Bunge, in his "Physiology," cites the report by a Swiss merchant, Charles Breuer, who had lived in India for a long time, of a religious celebration which took place in 1895 in the presidency of Madras. A fakir was placed in a trench, his body was covered with a cloth and then by earth. This occurred at eleven o'clock in the forenoon; at five o'clock in the afternoon the body was disinterred and resuscitated. During the entire time a large number of spectators was present, and Breuer

himself witnessed both the interment and the disinterment.

Of course, it is very difficult to say whether much contained in these reports is not due to errors of observation. According to Schmidt, the four cases of Braid occurred between the years 1828 and 1857, and, in all probability, represent various "deaths" of one and the same person, the Yogi Haradas, who came from the neighborhood of Karnul. Garbe says that the reports by Hindoo natives of apparent deaths of the Yogis "have but little value for those who recognize the untrustworthiness of the modern Hindoos."

Even if all these reports are exaggerated, even if the trustworthy ones are only those which tell of the Yogi's sleep in the open air and of cases in which heart action and respiration showed no marked variation from normal conditions, still there must be involved in them a question of prolonged hypnosis, of a cataleptic state. Hence they must be of interest in showing the extent to which bodily functions may be influenced by suggestion, by the concentration of the will and the imagination upon a certain idea.

C. Forms of Suggestion

In a more special discussion of the various forms of suggestion, it is advisable to take up first the difference between waking suggestion and hypnotic suggestion.

There can be no doubt whatever that premeditated psychic inoculation is most easily effected in a special condition of consciousness which is called hypnosis. We are usually able to avoid the use of this method, however, since in a large number of persons a further increase of the naturally great receptivity and impressionability is superfluous. Furthermore it is frequently difficult, and, for the unpractised hypnotist, occasionally impossible, to produce the hypnosis necessary for an increase of suggestibility. As a rule, therefore, we shall have to confine ourselves to suggestions made during the waking state. Those, in the majority of cases, not only are adequate, but also enable us to avoid the various dangers associated with hypnosis, especially as practised by the unskilled.

He who, through lack of experience or because of ignorance of the technique, is in doubt regarding his ability to implant suggestions by means of

hypnosis, will be able, notwithstanding, to attain results by the persistent use of suggestive influence during the waking state. Still it will be useful to know the main characteristics of the hypnotic state.

Hypnosis, as the word indicates, is a sleep-like state produced by artificial means. The condition is brought about by suggesting the idea of sleep and by the acceptance of the suggestion on the part of the person to be influenced. The question immediately arises, Is the condition produced by the suggestion of sleep an actual sleep? As to that, opinions differ widely. Certain authors, including Wundt and Krafft-Ebing, deny there is any similarity between the hypnotic state and sleep; others consider the two states identical; still others adopt a middle course, designating the lighter grades of hypnosis as states not akin to sleep, while deep hypnosis is regarded by them as actual sleep.

The difficulty of answering this question lies in our ignorance of the physiological conditions which exist during sleep. In sleep, the attention—that is, the power of concentrating the psychic energy on certain concepts—probably is divided equably among all the sensory organs. In consequence of this equable distribution, it is impossible, accord-

ing to Hirsch, for any individual function of the brain to become efficient to the same degree as in the waking state.

Indeed, it may be said normal sleep occurs through not concentrating the attention, through not thinking of anything definite, through not directing the sensory organs toward a definite point —in short, through closing them to external stimuli. The more such equalization occurs, the stronger does fatigue become, and when it reaches its height, sleep occurs. Sleep does not occur in consequence of the attention being concentrated upon the idea of sleep, for, as is well known, many people fall asleep entirely against their wills, even when they voluntarily distract their attention from sleep, and often under very inappropriate conditions.

Accordingly, also, the process of awakening, after brain and body have become rested, probably takes place through the gradual reconcentration of the attention, which, during sleep, has been distributed equably in individual perceptional centres. When such reconcentration is taking place, any sensory stimulus, a stream of light, a noise, etc., which is not perceived during sleep, may be

ample to make an impression on consciousness and cause the awakening.

The main distinction between sleep and hypnosis is furnished by the state of the attention. Whereas in sleep the attention is equably distributed, in hypnosis we find it concentrated on the idea of sleep. The hypnotized person merely believes he is asleep, he has the illusion of sleep without really being asleep. That is corroborated by the fact that people in natural sleep usually are not amenable to suggestion. Since the attention, in hypnosis, is directed toward a certain idea, consciousness is not altered in the same manner as in sleep. The hypnotist can place himself in communication, en rapport, with the object of the experiment, and can receive answers to his questions. It is said to be possible by this means even to inveigle the hypnotized person into revealing his innermost secret—that of a crime, for instance. Here, of course, we cannot enter on a discussion of the question whether such a procedure is justifiable, or whether, assuming all inhibition to be removed during hypnosis, divulgence of such secrets may be attained with any degree of certainty.

It is a fact, however, that we cannot place our-

selves en rapport with a sleeping person, and for that reason alone hypnosis is not identical with actual sleep. On the other hand, it is possible to transform sleep into hypnosis, or hypnosis into sleep. In the former case a rapport may be subsequently attained, in the latter case the rapport at once ceases.

Various additional points might be adduced to indicate the difference between sleep and hypnosis —such, for instance, as the fact that the closure of the lids which characterizes natural sleep is not necessarily present in hypnosis; the regular experience that going to sleep takes much longer than being placed in a state of hypnosis, which usually is attained in a few seconds; and the absence in hypnosis of the sensation of fatigue, which is concomitant with going to sleep. In the main we must agree with Hirsch that the chief difference between the two states rests in the fact that in natural sleep the attention is incapable of concentration and is therefore ineffective.

Still, since hypnosis is a sleep-like state, we are justified in contrasting it with the waking state. We must reiterate that during hypnosis, since the attention is directed to the concept of sleep, the

will power and judgment are markedly weakened, if not entirely suspended, and for that reason alone suggestibility is increased. Suggestions, therefore, may become fastened and realized more easily than in the waking state.

Nevertheless, we must insist that even without hypnosis, and without the usual accessories associated with it, such as the fixation of lustrous objects, stroking and other manipulations employed for the purpose of increasing the subject's credulousness, the simple verbal method of suggestion is entirely and promptly efficacious in the majority of instances. If we succeed in obtaining the acceptance of a suggestion, the emotions, the sensory perceptions, the impulses of the will, etc., which correspond to the suggested idea, will become operative, in accordance with the law of ideodynamics, or of the power of thought, first formulated by Bernheim.

In connection with the discussion on hypnosis, we must briefly mention the manifestations known as "subconscious" and their corollary, alternating personality.

The studies and investigations devoted to the hypnotic state, with the special attention given to

the memory of hypnotized subjects, soon showed that the memory remained unaltered during the lighter degrees of hypnosis. Throughout such superficial hypnosis the subject retains his recollection for all occurrences of waking life, and, after the hypnotic state has passed away, for all which has taken place during that state. Even the slightest lapse of memory cannot be discovered. But in the deeper grades of hypnosis the conditions are entirely different. A characteristic of those states is the post-hypnotic amnesia, loss of memory of what the person has experienced during the hypnosis. This loss of memory, which may be termed the direct mark of differentiation between superficial and deep hypnosis, is, however, by no means complete. The memory pictures which apparently have faded can be revived by means of a fresh hypnosis.

In the new hypnosis the memory impressions received in the preceding hypnosis will again be present. Even in the waking state an experience of the hypnotic state which apparently has been obliterated can occasionally be recalled. This takes place when conditions similar to those which have brought about the first impression arouse

the dormant recollections by means of association of thought. In this manner dreams and experiences of the waking state which have apparently been forgotten entirely, may reappear suddenly, distinctly, and clearly. If, on the other hand, many sensory perceptions disappear from memory without leaving a trace of their former presence, it is because they have left no impress on the brain, for, as we have already stated, such impress takes place only when the sensory perception is accompanied by the requisite attention. Whenever such attention is lacking, when the mind is busied with other matters or is incapable of concentration, the sensory perceptions will pass by without leaving a record; then recollections of their happening cannot be revived by a recurrence of like or similar conditions.

Memory is dependent on actual brain impressions and on the existence of association fibres by which these impressions are interconnected. It is immaterial whether these impressions have been produced in the waking state, in a dream, or in hypnosis. If the same or similar conditions are not reproduced again to stimulate the association fibres, the impressions will sink into oblivion, to

be recalled at once, however, when such conditions are reproduced again.

In hypnosis such reproduction is effected artificially when, through association of ideas, the imparting of the experience of a former hypnosis forms a bridge, so to speak, between hypnosis and hypnosis, or occasionally between the hypnotic and the waking state. But where have these memory images been during the time they have been unable to force their way into consciousness? They could not have been actually effaced, since an association of ideas or a renewed hypnosis has again brought them to light. The answer is that they were latent in the brain, in a sphere of consciousness which has been designated the "subconscious or subliminal mind," in contradistinction to the supra-conscious or supra-liminal mind, which takes in the perceptional contents always present in consciousness. On this basis Dessoir has constructed his theory of dual personality. The concepts present during hypnosis would fall, therefore, within the domain of the subconscious. Dessoir even goes so far as to look upon all hypnosis as a state in which the subconscious self occupies a dominant position, displacing the supra-conscious self.

To me it does not seem that the term "subconsciousness" has been happily chosen. The word may give the impression that there is a contradiction between subconsciousness and supra-consciousness. Yet the one does not exclude the other, as, for example, the word "day" excludes the idea of night, light excludes dark, right excludes left. We must always remember that subconsciousness does not stand for any new thoughts, but is essentially made up of memory images. For this reason I agree entirely with Prince, who prefers the term "co-consciousness." This quite correctly expresses the idea that, beside the main consciousness there exist perceptional contents which are not always present and apparently have left behind no brain impressions, but which, through purposeful or accidental stimulation of the association fibres, may be recalled to memory at any time.

This explains the facts mentioned by certain observers, which at first blush seem rather mystical. I would recall to mind the case mentioned by Obersteiner of a servant girl who, while in hypnosis, cited Hebrew phrases, but during the waking state had no knowledge of that language nor any recollection of ever having known it. It was shown, however, that this knowledge had come to her in

an entirely natural way. Years before she had been in the employ of a pastor whose custom it had been to read aloud the Hebrew biblical texts, and these she evidently had learned without in any way understanding them. It certainly is not unusual for persons in hypnosis to live in a world of thought entirely foreign to that of their waking state. Out of that condition of affairs grows the idea of a double self or dual personality. It is this which has helped to surround the hypnotic state with an atmosphere of mysticism, and which has caused the belief that some demonic or supernatural force controls hysterics, who, on the one hand, are easily hypnotizable, and, on the other, are so changeable emotionally that they often present the picture of dual personality.

It is now in order to take a cursory view of the condition which the spiritists designate as "trance." In this state, which is identical with hypnosis or somnambulism, the spiritistic mediums, figuratively speaking, are said to be transported from earth and endowed with the power of second sight, clairvoyance. Then, it is asserted, they manifest knowledge which goes far beyond what should be expected of them in view of their educational

opportunities. The spiritists explain this by the assumption that the mediums, when in a state of trance, are the interpreters of people who are dead, and, therefore, that it is not their proper self which gives expression in the trance to so-called supernatural knowledge, but another self—namely, the spirit of the departed. As a matter of fact, in these cases it is a question essentially of the revival of memory images which have passed out of consciousness and which, perhaps for many years, have lain latent in the subconsciousness, or co-consciousness. The use of foreign languages in the trance is also to be explained in this way. Thus Laura Edmonds, daughter of Justice J. W. Edmonds, of New York, was able to speak nearly all languages in which conversation was sought, although, according to her father's statement, in a waking state she knew only her mother tongue, English, and a little school-girl French. When in a trance she also sang in foreign languages.

Such powers have been manifested by other mediums, too. Quite as singular is the answering of scientific questions in a state of trance by a medium who, when awake, is unable to impart any information whatsoever on such subjects.

Spirit-writing, or the transmission of a spirit's "thoughts" in writing by the hand of a medium, is usually effected by means of the psychograph. Varied constructions of this apparatus are seen. A common one consists of a light, freely movable bar or pointer on a board on which letters of the alphabet, the figures 0 to 9, and many of the commonest words are printed in a circle. The medium places his hands on this board, and then the pointer moves to and fro, from letter to letter, thus forming words and sentences. The planchette is a variety of psychograph.

Automatic writing, spirit-writing without the use of apparatus, is effected as follows: A pencil is held by the medium in a writing position over the paper; when the attempt is successful, the hand moves as though under foreign influence; often many futile attempts are first made, the writing then representing nothing but a confusion of lines and dots, from which ultimately a legible writing is developed. It also is asserted "spirits" send direct written communications, in which the pencil is moved by the "spirits" themselves, and the writing is done on covered or concealed sheets of paper. The statement of the spiritists that this

form of communication is the highest manifestation of spirit life, when considered together with the concealment necessary for its effectiveness, suffices to characterize the entire procedure as a piece of dextrous sleight of hand, which can impress none but the credulous mind.

As a matter of curiosity, let us here relate an example of direct writing which has been designated by the spiritists as a "great success," and which shows that even the most learned men may become victims of deception when they abandon the field of fact for that of speculation. This example is taken from the report of a séance, at which Professor du Prel and Baron von Hellenbach allowed themselves to be mystified by the well-known medium Eglinton. As du Prel tells the story, Eglinton, on being left to himself, soon went into a condition in which, evidently, he no longer acted consciously, but was governed by instinctive and involuntary impulses. He next sat at a table, arising now and then, walking about, and speaking in an altered tone of voice. He asked von Hellenbach for some clean paper, and, taking a single sheet from a package of rather stiff sheets of notepaper of the size of a postal card, placed it on the

table. Then, going to a bookcase, he took out a book which happened to be Zoellner's "Transcendental Physics," and which also was placed on the table. Tearing a corner from the sheet of notepaper, Eglinton placed the torn bit in du Prel's hand, and the empty sheet, together with the point of a pencil, in the opened book, which then was immediately closed. Eglinton kneeled between du Prel and Hellenbach, and all three joined hands on the closed book. Hellenbach asked a question relating to his studies which required a long answer. After a few seconds, du Prel, having the feeling in one of his hands that writing was going on within the book, placed his ear on the volume and distinctly heard the muffled sound corresponding to rapid writing on material of such a nature. Three quick knocks from within the book announced that the unknown "spirit" had completed its work. When the book was opened, the previously clean sheet was found covered by thirty closely written lines. From a corner of the sheet a piece was missing, and the torn edge fitted exactly with that of the piece in the possession of du Prel. A repetition of the experiment furnished the opportunity for a completion of the answer.

Du Prel says particularly that the writing bore no resemblance to that of Eglinton, and that, by the light of three gas-jets, every movement of Eglinton could be carefully observed. He gives it as his opinion that no deception could have taken place.

Any one who has attended spiritualistic séances, and who has been a witness of the manner in which even the most intricate exhibitions of so-called mediums have been surpassed by expert prestidigitators, must be able to form his own conclusion as to the value of such experiments. So far as automatic writing is concerned, we would only recall what has been said concerning the involuntary bodily movements always associated with psychic processes. That these movements may give to the pencil a certain direction is evident. At times the meaning of the written communication is without sense or ambiguous; at times a clear meaning is given. In the latter case, careful study always will show that the apparently foreign thought is not a new revelation, but represents that part of the general conceptive contents which has lain dormant in subconsciousness, or, rather, co-consciousness. That such processes of thought may be elicited during trance or hypnosis without

having been suggested is explained by the augmented powers of recollection which accompany those states, and which condition is known as hyperamnesia.

We have already mentioned that, during hypnosis, there may be observed in certain persons a complete dissociation of consciousness which bears the impress of dual personality. The case of the woman Ilma Szandor, to whom had been suggested the seventh year of her life and loss of memory for the entire period which had elapsed since that time, so that she believed herself to be a child and looked upon her surroundings from a childish view-point, as well as the case of the young man who, during hypnosis, was transformed from a mild and timid into a valorous and intrepid person, depends solely on the power of suggestion and the alteration in the conceptional contents produced thereby. An entirely different interpretation must be given for those cases of dual personality in which, through accident or disease, certain association tracts have been destroyed or barred out, so that the memory images for certain periods of life cannot be reawakened by any known means.

Finally, let us take up briefly the differences

between auto-suggestion and foreign suggestion. There are suggestions which arise apparently spontaneously, without any influence of other people, which depend on an idea starting in the individual himself, and are therefore designated as auto-suggestions. The formation of an auto-suggestion may be caused by an association of ideas. Take the case of a person who has undergone a painful operation at the hands of a physician. Later, if he is obliged again to consult the physician, the auto-suggestion will arise that he must again submit to a painful operation.

Moreover, numerous pathological manifestations depend on auto-suggestion caused by association. The nervous vomiting which affects so many people may well be caused by the fortuitous occurrence of a single attack of vomiting after a heavy meal, followed by the auto-suggestion that this vomiting will recur after every subsequent meal. Numerous idiosyncrasies against certain foods or odors are perhaps to be explained in the same manner. Furthermore, Moll calls attention to the fact that the imperative concepts, obsessions, such, for instance, as the fear of open spaces (agoraphobia), owe their origin to auto-suggestion. The agora-

phobic patient becomes dominated by the idea that he cannot traverse an open space, his own will is too weak to withstand this auto-suggestion, and every attempt to traverse an open space brings forth the typical feeling of fear. Similarly, numerous hysterical paralyses are dependent on auto-suggestion. We shall become acquainted later with many forms of disease whose ultimate causation is the result of ideas produced through auto-suggestion.

That auto-suggestions may arise in consequence of sense deceptions is also undeniable. As opposed to auto-suggestions which arise against one's will stand those which are produced consciously by one's will. Hirsch cites a drastic example, mentioned by his former teacher, the physiologist Preyer, in his lectures as proof of the possibility of an intentional auto-suggestion. Preyer recounted that he never allowed his study to be heated, but utilized his will power—that is, his capability of auto-suggestion—to eliminate the sensation of cold. By means of the auto-suggested sensation of warmth, it became possible for him to work in comfort in a cold room and to bathe in ice-cold water.

In the same category belongs the power, emphasized by Kant, of mastering one's disordered

feelings, by the mere exercise of will—that is, by auto-suggestion. As a matter of fact, all suggestions, even those which come from another person, act through auto-suggestion, since even the foreign suggestions must become fixed and elaborated, must be adopted by the brain of the person to be influenced, before they can become efficacious.

D. Suggestion—Its Past and Present

It has seemed advisable to me to defer a consideration of the history of suggestion until the reader has become acquainted with the terms and definitions of the subject, instead of following the usual custom of making use of such retrospect as an introduction. Especially important did it seem to me to show clearly at the start that certain functions are of psychic causation, and therefore amenable to psychic influence. The same consideration also will constitute the basis for what is to follow. Let us begin, therefore, with those functional disorders which are of psychic production, those caused by suggestion and which, as already indicated, come under the designation "psychic contagion."

From olden times there comes to us knowledge

of a species of psychic disorder which manifested itself in a belief that the afflicted person had been turned into a wolf or a dog. These patients, especially with the approach of spring, were swayed by an irresistible impulse to follow the habits of wolves and dogs and to pass their nights in lonesome burial places.

The old and wide-spread belief in the existence of man-wolves seems to have furnished the basis for this delusion. In not a few instances this fancy has become epidemic and hundreds of persons have become cannibals, going on all fours, living in forests, and howling like wolves. Other persons imagined themselves to be dogs and went about snarling at all whom they passed. In some cases, without having been bitten, or without even having come in contact with dogs, they barked, frothed at the mouth, and in every act simulated rabies. This spurious hydrophobia, of course, had nothing in common with lyssa, or true rabies.

Zander relates that Marcellus of Sidoc in Pamphilia, a Grecian physician of the time of Marcus Aurelius, has described such a lycanthropic epidemic in hexameters, and from a later Arabic author we learn that in the sixth century B. C.

this cynanthropy or lycanthropy was endemic. In his "Contributions to the History of Medicine," Boettiger of Weimar adduces the oldest references to wolf-madness from Grecian mythology, and from this source we note that nearly all the barbaric tribes of the Middle Ages were afflicted at some time or other by this obsession.

Even in more recent times the man-wolf occupied so prominent a place in connection with the prosecution of witches and sorceresses that there can be little doubt that this form of mental disorder, evidently due to hallucinations caused by suggestive or psychic contagion, must have been epidemic, and that much of the belief in witchcraft and sorcery owes its origin to this cause.

In 1600 many scores of people in the Jura were executed for lycanthropy, and about this time a French judge named Boguet drew up a code in which he permitted ordinary witches to be strangled before they were burned, but provided that lycanthropes were to be burned alive.

Most noteworthy examples of the communicability of morbid nervous manifestations and of the wide distribution of such psychic epidemics are furnished not only by the witchcraft prosecutions,

but also by the associations of flagellants, by the children's crusades, and by the dancing madness of the Middle Ages. Witches, who, in all probability, were mostly hysterics, were supposed to be possessed or controlled by some evil spirit. All their actions, their appalling cries, the contortions of their bodies, the atrocities which they committed, were the work of the devil within them. Exorcism was the only cure. When this devil could not be driven out, incarceration, racking, and burning to death were the logical means of reaching the seat of the trouble.

The records of these witchcraft prosecutions, the drawings and paintings of that time, leave little doubt that a large number of the witches were sufferers from hysteria and that this disease furnished fertile soil for the development of all manner of sense deceptions and suggestions. Scourging, or flagellation, having been encouraged by the popes and prominent churchmen as a means of religious discipline, for penance and expiation, became popularized by the mendicant friars. In 1261, when Italy was under the bane of the greatest profligacy, according to the Monachi Patavini Chronica, a piety hitherto unknown suddenly over-

came first the inhabitants of Perugia, then the Romans, and finally spread among almost all the people of the country.

In processions of hundreds and thousands, at night with burning candles, naked even in the most severe winter, and headed by the priests bearing crosses and flags, the gentry and the common people, the old and the young, even children, marched through the streets of the towns scourging their bare bodies until the blood flowed, moaned and called upon God and His mercy, and threw themselves upon the altars in supplication. Some of these processions marched even over the Alps, and found imitators in Carniola, Styria, Austria, Bohemia, Moravia, and Hungary.

In 1348, in consequence of the desolating plague called the "black death," which spread from Asia through all of Europe, and which was looked on as a divine visitation, these same scenes were repeated, and this time Germany was not exempt. Associations of flagellants marched from place to place, praying and scourging themselves with knotted ropes. Like an avalanche these hosts grew and spread, drawing every one with them.

Additional evidence of the power of suggestion,

or psychic contagion, is furnished by the so-called children's pilgrimages, or children's crusades. These were taken part in by thousands of young people of both sexes, most of them between the ages of twelve and eighteen. Aventinus, in his Chronica, describes the first of these crusades, which took place in the year 1212, the children marching through Saxony, South Germany, and over the Alps to the borders of the Adriatic.

Without a leader, without means of subsistence, without money, sustained solely by their intense enthusiasm, these young wanderers began their pilgrimage for the purpose of delivering the Holy Sepulchre from the dominion of the Turks. Soon they were joined by men and women. Thieves and scoundrels associated themselves with the youthful crusaders, robbed, and plundered them. Many died from want and deprivation; some reached Genoa; others turned back, and, barefooted and hungry, exhausted from cold and suffering, derided and insulted, they again reached their homes.

A similar pilgrimage which started from Paris fared no better. A pilgrimage of one hundred children from Erfurt in 1237 also came to a tragic

end. These children started out dancing and singing, but soon fell exhausted by the wayside; many died, and, according to report, the others became afflicted with a tremor which remained with them for the rest of their lives. The last of these pilgrimages set out in 1458 for St. Michael in Normandy. Aventinus described this crusade as follows:

"Unexpectedly the children came; they had to run along. It was said that those who wanted to go along, but were restrained, would die. Many died of hunger, many were frozen to death, and some were captured in France and sold into bondage; not one came back to its home. The mothers could not hold back those who wanted to start. There followed a great pestilence."

In this connection let us recall what we have previously said regarding the power exerted by erroneous ideas, even when they are in no way dependent on organic disease of the brain. To-day, when among civilized peoples the scepticism due to cultural enlightenment has made the atmosphere immune to such contagion, these children's crusades are no longer possible. The same may be said of the dance madness of the Middle Ages.

In the year 1374 scores of dance-mad men and women appeared at Aix la Chapelle and danced for hours in a wild delirium, in churches and on the streets, until they collapsed from exhaustion. In many of them there ensued a tense expansion of the abdomen, of which they tried to rid themselves by tight bandages, by blows and kicks. During the activity of the dance, it seems, all sensory impressionability was eliminated. The imagination of the dancers held full sway. All manner of visions were conjured up before their eyes; they saw spirits whose names they muttered, and later they said they had believed themselves to be immersed in a stream of blood and had jumped so high in order to avoid it. Others, in their transports, saw the gates of Heaven ajar, with the Saviour and the Virgin Mother upon a throne, ready to receive them. This dance-madness, in many instances, was preceded by convulsions.

A fresh outbreak of this disease, which meanwhile had spread from Aix through Belgium and Holland, and along the upper Rhine, occurred in Strasburg in 1418. By order of the magistrate, the dancers were led in troops to the Chapel of St. Vitus in Zabern, there to be pacified by the

saying of mass, by prayers, etc. This dance-madness became extinct with the close of the fifteenth century, but along the Rhine traces of its existence are still to be found, as is shown by the annual saltatory procession to the grave of St. Willibrad in Echternach.

These examples which we have presented are instructive in many ways. Above all they show how persons with but little strength of character and of feeble will power—yes, even entire masses of people—may, by means of any idea and the imitative impulse, be stirred up to the commission of even the most absurd deeds. But they also show that the interpretation of these vagaries by the people of the Middle Ages did contain a justifiable nucleus. Ever since psychology and psychiatry have been dominated by scientific tendencies, we have endeavored to find a material substratum, some organic alteration which might be held responsible for any disorder, not only of the body, but also of the mind. Nevertheless, we are still warranted to-day in stating it as a law that a number of functional symptoms and disorders are psychically produced—needless to say, not by means of demonic possession, as was the mediæval

belief, but through the power of suggestion. The significant difference between our explanations and those of the mysticists, therefore, rests in this—that ours is founded on natural psychical causes, while theirs was based on supernatural and extraterrestrial causes.

The justifiable nucleus of the otherwise abstruse views of the Middle Ages, however, is to be sought in the fact that disorders of function, disturbances of body and brain action without any pathologico-anatomical basis, do exist. This view must be accepted as correct until the microscope and other refined methods of investigation will have demonstrated that these "functional" disorders and symptoms, too, are nothing else than manifestations of morbidly altered structures. That time has not yet come. If it be admitted that the people of the Middle Ages were correct in their assumption that hysteria and other neuroses were psychically induced, then their mode of treatment by psychic means cannot be considered at fault.

Diabolic possession can be treated only by exorcism of the demon. Deride this as we may, we cannot accuse our ancestors of having been illogical in their conclusions. To-day, instead of exor-

cism, we employ another means of treatment, one more in accord with our advanced knowledge, yet withal a psychic one.

Natural causes demand natural remedies. Psychic infection is quite as natural a process as is the physical infection due to bacteria. Similarly, the suggestion which we employ for the cure of such psychic infection is no less a natural remedy than, for instance, the Jesuit's bark used to cure malaria.

Fundamentally, therefore, nothing can be said against the point of view of the Middle Ages. Neuroses, being of psychic origin, may consequently be influenced by psychic means. Moreover, the far past had other explanations also to offer for the occurrence of hysteria and allied neuroses than that of diabolic possession. Natural causes, too, were acknowledged, and natural remedies were employed.

Of all things let us not lose sight of the fact that the cure or alleviation of disease through psychic influence is by no means a product of modern times. Inscriptions found on many of the most ancient monuments bear witness to the success attained in the cure of disease through mental influence. In fact, it may truthfully be said that the

methods of influencing the mind were better understood thousands of years ago than they are to-day.

What seems most amazing, however, is the fact that the sleep-like state which to-day is called hypnosis was known to the ancients and was employed by them for therapeutic purposes. Unquestionably the "temple sleep" of the old Egyptians was simply a hypnotic state. The priests, to whom, as is well known, was allotted all treatment of disease, were the ones to bring about this sleep. The patients were subjected to various preparatory ceremonies, which probably served to augment their faith and to increase their impressionability. It is quite likely that the baths, the fasting, etc., which formed part of the preparations for the "temple sleep," constituted, through their hygienic influence, an important factor in the production of some of the cures of the priests. During this sleep the patients, in answer to questions propounded by the priests, proclaimed the remedies which would restore them to health. These answers were considered oracular. It may also be assumed that the information obtained by the priests during this hypnosis furnished them with much knowledge of the previous life, as well as of the ordinary men-

tal processes of the patients. Thus was gained knowledge which became of the greatest value for future suggestive treatment and which could not have been obtained during the waking state.

Nor was the psychic aspect disregarded in the application of other medical ordinances. Even in the prescription of medicines, whose activity was certainly not underrated, the physicians of times long past deemed it useful to augment the mental influence on their patients by the addition of certain magic formulæ to the recipe.

Among the Hebrews the practice of medicine, exercised by the Levites, consisted in an appeal to the Deity and in sacrificial offerings, for which, when they were abolished in a later period, prayers were substituted. In a similar manner the art of healing among the old Greeks was clad in a religio-mystical garb. The oracles of renown, those of Æsculapius at Epidaurus and Pergamus, and that of Apollo at Delphia, attracted sufferers from all diseases from far and near.

In the case of the Greeks, too, as among the Egyptians, the "temple sleep" revealed its powers. Large "sleeping houses" were erected in the temples, and in these the patients, while in their sleep,

received divine utterances, probably suggestions by the priests. A certain amount of reverence was attached to this "temple sleep," too, by the Romans, for whom the prognostications of the Sibyls, as well, were of great significance. The peculiar condition which overcame the Sibyls during their utterances seems to have been closely allied to hypnosis, if it was not an actual hypnotic state. The Persian Magi also knew how to place themselves in a state of hypnosis, using the method of fixation. The Indian fakirs of to-day use the same method. So, in the fourteenth century, the monks upon Mount Athos, that body known as Omphalopsychites or Hesychasts, placed themselves in a hypnotic state by deep contemplation or by fixation of the navel. Let us pass by that period during which Theophrastus Paracelsus attempted to demonstrate the influence which the astral bodies exercised on one another, and, more particularly, on human beings and their diseases, and thereby laid the foundation for that doctrine of animal magnetism which in 1775 became generally known through the efforts of the Viennese physician, Friederich Anton Mesmer, and which, though erroneous, must be recognized as the forerunner of modern psychotherapy.

It was known long before Mesmer's time that animals could be put into a hypnoidal state of passivity. As early as 1646, Kircher, a Jesuit priest, had "mesmerized" chickens so that they remained motionless in any posture in which they had been placed. Two hundred years later, Wilson, in London, followed up these experiments by imposing a cataleptic state upon wolves, horses, and other animals. Further successful experiments of this kind have been conducted by Verworrn, the renowned physiologist of Goettingen, upon birds, snakes, frogs, and guinea-pigs.

Hollander calls attention to the fact that in Austria the law requires army horses to be mesmerized in order to shoe them. This procedure was introduced by a cavalry officer named Balassa, for which reason it is now known as "balassiren." By this method, says Hollander, "horse-tamers tame the wildest colts and the most vicious horses in an hour."

This "mesmerizing" of animals has nothing in common with the suggestion exercised upon human beings except the state of passivity of the will which is thereby produced. Through fear or fright the animal is thus placed in a condition of muscular

rigidity, known as catalepsy, during which it is unable to resist anything which may be done with it. Of course there is involved here no question of any psychic contact, of any "rapport" between the animal and the experimenter, yet remarkable results have been achieved through such balassing, or mesmerizing, of animals. Lion and other animal tamers, Hindoo fakirs, who at will place their poisonous snakes into a state of complete immobility or wildest furor, all exert their apparently marvellous powers through a dominance achieved by fixity of eye and general comportment. The ruler of animals or of human beings always owes his successful psychic influence in part to an imposing dignity which he may possess; but that which may be attained in animals only through fright or fear is effected by the suggestionist of human beings, through psychic contact, through the production of certain ideas.

This doctrine of animal magnetism entered upon a new phase when in 1814 Abbé Faria, of Paris, expressed the conviction that a magnetic fluid did not exist, but that the production of the phenomena of animal magnetism was entirely dependent on the will of the subject on whom the experiment

was being carried out. Since it is this principle which constitutes the fudamental idea, as we have already learned, in the causation of the manifestations produced by suggestion and psychotherapy, we must accord to Faria the credit of having been the first to recognize this truth. The views of Faria having been adopted in France, more particularly by Bertrand and Noizet, the Paris Academy of Medicine in 1826 appointed a commission to investigate the entire question of animal magnetism. Forty years previously, as a result of an opinion given by this same academy, the employment of so-called magnetic treatment (mesmerism) had been forbidden. Now the Paris commission recognized as true, within the limits placed on it by Faria, the manifestations produced by animal magnetism. Preyer says that, if to-day we substitute the word "hypnotism" or "suggestion" for the word "magnetism" wherever it occurs in the report of the French Academy, we should have no reason to find ourselves in disaccord with the thirty theses enumerated by that body.

Next to Faria, most credit is due to the English surgeon, James Braid, for our advance in knowledge regarding suggestion and hypnosis. Stimulated by

public exhibitions given by a French magnetist, La Fontaine, Braid in 1840 began his independent investigations, which culminated in the conclusion that a person may pass into a sleep-like condition as a result of intent fixation of a glistening object. This state, to which Braid applied the designation "hypnosis," was employed by him for the production of anæsthesia, of which he made practical use in his surgical operations. In his book, "Neurypnology," published in 1842, Braid says that concentration of the attention on the glistening point is as necessary as fixation.

Although Braid was the first to explain clearly the increase of suggestibility which is present during the hypnotic state and to make use of this condition of augmented suggestibility for therapeutic purposes, yet he undoubtedly started from a false premise. He considered the fixation, the physical stimulus, as the chief causative factor in the production of suggestion and hypnosis, while he entirely overlooked the psychic factor, the will of the subject, on which Faria had laid stress.

Faria's doctrine, however, did not receive a scientific foundation until Liébault, the physician of Nancy, took the matter up and showed that the

verbal method, the influence of words alone, was sufficient in itself for the production of suggestion, provided the suggestion were accepted by the person to be influenced. If, however, the constitutional character of the subject oppose the suggested idea, then its acceptance and consummation may be effected neither by fixation nor by verbal hypnosis.

Although a beam of light had thus been cast into this chaotic confusion, Liébault for a long time did not receive the recognition which was his due; he, too, had to learn by bitter experience how difficult it is for people to comprehend the most simple facts. It apparently was easy to believe that mystic supernatural influences could be transmitted to human beings by means of complicated artifices and manipulations, as was done by the old oracles, religious cures, and animal magnetism; but to accept comprehensible truths, and to exclude all that was supernatural in the explanation of recognized facts, seemed wellnigh impossible at a time which was still under the influence of Schelling's philosophy of nature.

Not until Bernheim of Nancy succeeded in promulgating Liébault's doctrines among the general public did they attain any measure of acknowledg-

ment. The existence of a certain opposition between the school of Nancy and that of Paris has already been mentioned. Charcot promulgated and defended, but by no means succeeded in proving, the theory that hysterics alone were amenable to the influence of suggestion and hypnosis. The Nancy school, by means of thousands of observations, has refuted this claim, and has clearly demonstrated that, although hysterics are exceedingly susceptible to all functional disorders originating in fallacious ideas, and, consequently, furnish excellent material for the exercise of all forms of psychotherapy, yet all this is true of other neuroses, as well as of organic diseases, to a certain extent.

We must yet refer briefly to those investigators of more recent times who have aided by their work in promulgating the doctrines of suggestion and its psychotherapeutic application. The list is a large one, and only a few names can be mentioned here.

In America, the names of Prince, Putnam, Sidis, and Muensterberg stand for all that is best in actual scientific work. The Society for Psychical Research, on the other hand, has devoted its attention chiefly to occultism, to the mystic manifestations of mental life.

Among the foreign workers and writers we must mention, in Germany, Albert Moll, Preyer, the renowned physiologist, Max Dessoir, the philosopher, and Albert Eulenberg, the neurologist; in England, Lloyd-Tuckey and Hack-Tuke; in Switzerland, Forel; in Stockholm, Wetterstrand, and, in Russia, Bechterew. This enumeration of names, which should be much extended, by no means signifies that psychotherapy is without adversaries. Later we shall become acquainted with their facts and arguments; here we will merely say that such opposition is of favorable significance for the future of psychotherapy. The history of medicine clearly demonstrates that those procedures which have been at once acclaimed and enthusiastically received have been short lived, while those which have been slow of growth and recognition have been of permanent worth.

The opposition to psychotherapy is due in part to the failures which have inevitably followed the mistaken or unwarranted employment of this method of treatment. Not every physician is fitted for the practice of psychotherapy. He who is not thoroughly convinced of the efficacy of this remedy will not be able to satisfy the public of its value.

Apart, however, from the misdirected and unaccepted suggestions made by physicians themselves, the great bulk of failures undoubtedly is due to the practice of psychotherapy by persons without medical training, who, because of their inability to make correct diagnoses, can have nothing but therapeutic unsuccess. Only the physician schooled in psychiatry is able to recognize the cases which are adapted for psychic treatment, and he alone can avoid the dangers with which suggestion and hypnosis are beset. To these more attention will be given in a future chapter.

It cannot be gainsaid, on the other hand, that the lack of critical appreciation which has confounded faith, prayer, and miracle cures with true psychotherapy, is in large part responsible for the discredit which has been cast upon the latter. Nor can we deny that astonishing improvements have been achieved by "Christian Science," the waters of Lourdes, the contact of holy relics, etc., without the concomitant use of physical or chemical remedies. Yet we must repeat emphatically that in such cases of amelioration it has never been a question of supernatural, but always of quite natural, processes.

As will be demonstrated in a special chapter, the beneficial results accomplished in those cases must be attributed to a concurrence of fortunate conditions which have neutralized the disease-producing psychic cause by means of contrary suggestions. Never is there involved a question of any "miracle," of the abrogation of any natural law. There does not exist a single authenticated case of organic disease which medical science has failed to cure which subsequently has been cured by suggestive influence. Such a case, if it did occur, might justly be termed a miracle. Since the disorders and symptoms which are most amenable to psychotherapeutic action are those that are due to mental influences, it can be of little significance whether the beneficial result is obtained in one manner or another; but what we, as scientific physicians, must desire and demand is the recognition of the fact that these beneficial results are quite as dependent on mental influence as is the disorder against which the treatment is directed, and that the attainment of success should not be left to a fortuitous happening, but attained designedly in accordance with physio-psychological laws.

This chapter should not be closed without show-

ing, by examples taken from most recent occurrences, that even to-day suggestion, when subservient to superstition and fanaticism, may become a tool of obscurity and crime.

Bechterew gives a full account of the aberrations of those sects, so numerous in Russia, and exemplified by the Dukhobortsi and the Raskolniks, which, blindly carried away by some idea, impulsively follow the leader who proclaims himself to be directed by God's inspiration, but who is actually dominated by hallucinations and delusions of his own brain.

Toward the end of the last century, seven thousand Dukhobortsi immigrated from Russia into Canada. There they did not find what they sought, for they did not want to obey the laws of any State, nor be the subjects of any ruler but God. As "pilgrims of God upon this earth," they are unremittingly in search of a haven in which they may live undisturbed in accordance with their fanatical views.

Still more extreme are the Raskolniks. In them certain mystical ideas resurrected from mediæval habits and thoughts became, through psychic infection, the source of a series of crimes. The

mental influence exerted by the life in the Raskolnikite cloisters, the isolation from the outer world, the persistent fasting and praying, all these undoubtedly furnished an appropriate atmosphere for the development and maintenance of religious fanaticism. Thus it came about that, only a few years ago, by order of the nun Vitalia, twenty-five persons allowed themselves to be immured alive within subterranean walls. Bechterew justly remarks, "He who allows the details of this appalling occurrence, beside which even the most extreme manifestations of Buddhist Asceticism are cast into the shade, to pass before his mental horizon, must certainly say to himself that these martyrs, who could give themselves up to death with such peacefulness, could do so only as a result of an irrefutable conviction, implanted by means of suggestion or auto-suggestion, that through such burial alive they would become the possessors of eternal salvation."

Of the details of this dreadful example of aberrant religiosity we will merely mention that Kowalew, the executor of this mass interment, was a peasant of limited mentality, entirely under the suggestive control of Vitalia, whose commands he

accepted even after she, together with his own mother, wife, and daughter, had been entombed and covered with earth.

After this brief historical sketch, which has taken cognizance of only some of the facts characteristic of suggestive influence, and having seen that suggestion in the hands of individuals either insane or dishonest may become an instrument of the gravest danger, we will proceed to a consideration of that use of suggestion which seeks to combat psychic infection with its own weapons, psychotherapy. We shall show that this remedy, whether employed by itself or with other methods of treatment, is destined to become a source of great benefit to suffering humanity—always presupposing that it be employed the same as any other remedy by the adept and experienced physician.

PART SECOND

PSYCHOTHERAPY

I. GENERAL CONSIDERATIONS

A. Definitions

WHAT is to be understood by "psychotherapy" can easily be deduced from the preceding explanations. Etymologically the word admits of a double interpretation, cure of the mind (*ἡ ψυχή, ἡ θεραπεία*), as well as cure through the mind.

Psychotherapy differs from psychiatry in that it concerns itself above all with functional disorders, or, more correctly expressed, with functional symptoms and their removal. That these disorders or symptoms, psychically caused and dependent not on organic changes but essentially on erroneous ideas, may be influenced psychically—that is, by the awakening of correct ideas—has already been demonstrated and will be made clearer in the following chapters. Inasmuch, therefore, as psychotherapy removes false ideas and the dependent

functional disorders or symptoms, it is actually a "cure of the mind."

It can hardly be necessary again to recall that by "mind," in the medico-scientific sense, we understand those manifestations of the central nervous system which find their expression in apperception, association of ideas, and conscious activity of the will. Just as diseases are nothing else than manifestations of life under abnormal conditions, so, in so far as functional disorders and symptoms are concerned, abnormal conditions are represented by certain false ideas, the removal of which is the task of psychotherapy.

If, furthermore, we remember how intimate are the relations which exist between body and mind, especially between the higher psychic functions and their bodily organs, the brain and the nervous system, then we need but recall the law of psychophysical parallelism to appreciate at once that a beneficial reaction of psychotherapy upon the physical condition cannot be wanting. This does not alone mean that, with the passing of erroneous ideas, the dependent functional disorders must disappear, but it also signifies that purely physical diseases, associated with organic changes as well,

may be beneficially influenced by psychotherapy—of course, not directly, but by the devious channel of enhancing the confidence of the patient in the therapeutic power of medicinal remedies or any other curative factor which may be employed. Psychotherapy, therefore, is "cure of the mind" in so far as false ideas are removed, and, on the other hand, is "cure through the mind" in so far as purely physical states may indirectly be ameliorated by means of suggestive influence.

B. The Justifiability of Psychotherapy

After all that has been said, it may seem superfluous even to discuss the question of psychotherapy's inherent right to intervene in relieving human suffering. Nevertheless, we must not forget that there exists a constantly increasing number of learned, half-learned, and unlearned individuals who are of the opinion that the efforts of medicine and hygiene, hence also those of psychotherapy, cannot be made to harmonize with the aims of nature. Applying the law of evolution unrestrictedly to human society, these people say that nature, by means of the struggle for existence, strives to cause a survival of the fittest, but that it cannot attain this

aim in human beings as it can in plants and animals, because the science of medicine is steadily opposing its purpose.

By means of the intense competition for the possession of the restricted existing materials of sustenance, nature of itself weeds out the unfit. The final word of Darwinism, although Darwin himself disclaimed this application of the developmental law, may be taken to mean that the sick and the feeble, who are not equal to the struggle for existence and who fall a prey to every infection and other injury, should be left helpless to their destiny, that they should be allowed to succumb in the way animals and certain aboriginal peoples are left to their fate. Certain votaries of this prejudiced and fanatic point of view go still further and, following the philosophy of Nietzsche, who died insane, declare compassion to be a reprehensible frailty on the ground that it is opposed to the intent of nature. In the opinion of these persons, a strong and healthy race needs neither medicine nor hygiene, both of which serve merely for the artificial preservation of the sick and the infirm and, in addition, enable them to propagate their kind. Pestilence, disease, and the exertions inci-

dent to the struggle for existence, they say, are nature's means of selection; he who is not able to withstand such ordeals is destined for extinction, and medical science should not intervene protectively.

All of this may be answered by the recognized fact that civilization has completely changed the natural conditions of life, and that, for this reason, the law of development as affecting human society must be materially restricted in its application. The number of accidents occurring as a result of industrial conditions has been augmented proportionately with the progress in the development of technical appliances; nor, despite our vaunted civilization, has the number of those injured on the field of battle been diminished.

The victims of industry and of war may have been just the ones selected by nature for survival. Should we, then, leave them to their injuries and stand passively by, waiting to see whether their broken bones will unite, their torn tissues heal, their loss of blood cease, without intervention? So ridiculous is this thought that no person of intelligence can question the right of surgery to come to the aid of nature in such cases, and, in many instances, to forestall fatal results.

Material conditions have been so altered by civilization that to-day life is less a question of bodily than of mental fitness. For people living in a rough and uncultivated land, not yet influenced by cultural development, and for those who pass their lives in a primeval forest or on a lonesome prairie, the natural requirements are entirely different, of course, from those of dwellers in a densely inhabited community. Where the people are isolated and dependent on themselves, they require, in their struggle for existence, well-developed muscles and impregnable health, but where pioneer work is no longer needed other qualifications are essential.

Civilization causes a survival of the fittest in quite another sense than does nature. Our civilization could not persist and could not develop if pestilence, disease, and accident, through which the best cultural elements are often swept away, were allowed full sway. Nor should we lose from sight for a moment the fact that civilization has been the cause of numberless evils which originally did not exist and against which nature has supplied no means of defence. We ourselves can and must provide for such defence by scientific insight into

the origin of these evils and the methods of combating them.

It cannot but be considered fortunate that the very same civilization which, through interference with natural laws of life, has been the cause of so many new ills to man, should at the same time place in his hands, through the achievements of medicine and hygiene, the weapons with which these afflictions may be combated.

Animals are furnished by nature with all sorts of means of defence, without which they would be helpless against every attack. Once they have become domesticated these means of defence, being no longer necessary, waste away from disuse. Nature has not provided the domesticated animals with the implements which their subserviency to man makes requisite. The horse, when living in freedom, needs no artificial protection for its hoofs, but without such protection it soon goes lame on the pavement of our streets. Civilization, therefore, has altered the conditions under which the horse naturally lives and, making demands on this animal for which nature has made no provision, produces an affliction which can be forestalled or remedied only by civilization itself. This one ex-

ample suffices to show that medical science does not work against the aims of nature, but meets the altered conditions of life which civilization has produced.

Considerations of still another kind make the thought that medical science is superfluous, or even detrimental, appear absurd. Human beings are not animals among whom exists no law of morals, but only the law of superior force. Frequently the cultural elements of greatest worth are those which, in the sense of nature, are not fit. Not always does a strong body go together with a strong mind; sometimes the body is weak but the mind strong. Often the most valuable cultural elements, great scientists, inventors, writers, are individuals of infirm constitution, and yet their worth to progress is found to be far greater than that of the great mass of people.

The able, the robust, the healthy, therefore, are not necessarily the most precious. Darwin himself was an invalid the greater part of his life. How many valuable lives would have been lost to the world had selection been left entirely to nature! Then humanity would have consisted of none but the strong, but the fact that these powerful ones

had rid themselves of the sick, the infirm, and the helpless would mean at the same time a subjugation to atavistic instincts, in consequence of which the human race again would sink to the level of the brute.

So deplorable a state could be brought about only through the stunting of that which is best in man, of that which raises him high above the animal, and gives him the character of an ethical personality, the feeling of altruism. Nothing but cold, crass egotism can endorse the doctrine which places compassion and weakness on one plane.

Since, therefore, it is personal interest which bids the human race to preserve the sick and the feeble, in so far as they constitute valuable cultural elements, considerations of an ethical and altruistic kind demand that the same be done for those of inferior worth.

The endeavors of medicine and hygiene are rooted in a soil of altruistic sentiment, which looks beyond the mere question of benefit. Yet medical science does not desire artificially to prolong the lives of degenerated and incurable weaklings. Its aim is to make the weak strong, the sick well, to restore to them the joy of living and of usefulness

so they may again fulfil their missions in life. It aims at the recognition and the avoidance of those noxious influences which threaten human health and well-being at every step, and which modern cultural development has called into existence in the shape of new dangers and diseases in nowise ordained by nature.

It aims also, however, to protect the healthy against any injury which might be caused through the physically or mentally diseased. To stand passively by while the helplessly degenerate transmit noxious germs to healthy individuals would no longer be compassion but would be criminal weakness. All that has been achieved by medical science through prophylaxis and therapeutics is the outcome of laborious investigations the justifiability of which can be questioned only by visionary fanatics. Unfortunately even in this twentieth century there exist people who believe disease should be accepted with resignation as a divine dispensation. Instead it should be a matter of universal knowledge that disease is a result of our ignorance and disregard of natural laws. If the sins of the fathers be visited upon the children unto the third and fourth generations, it is a purely natural proc-

ess of development, which must take place even if there is no co-operation of supernatural powers. For any one who realizes thoroughly that it is as impossible for races as for individuals to return to a state of nature, to the days of childhood, from maturity to immaturity, from reason to belief, and that they must meet the age of maturation and independence with fortitude and decision, there can exist not the least doubt that in our battle against disease we cannot rely on nature to make any selection adapted to the requirements of civilization, much less expect any aid from chance occurrence or miraculous happening. Even from a religious point of view it would be unreasonable to expect that God would intervene between us and the orderly course of natural processes for the purpose of mitigating suffering of our own making, and for which there exists a natural relief.

It will be unnecessary to do more than refer to the fact that a belief in the miraculous is sure to be a hindrance to progress of all kind, in that it causes a passivity which allows every misfortune unopposedly to take its course. No words are truer than those of Horace, "Nihil sine magno vita labore dedit mortalibus," and we must learn that progress

is essentially a question of our own endeavors, and that the impulse which is innate in the human race, to defend itself against evils, whether dependent on our own misdeeds or not, has been implanted in us so we may learn to recognize the laws of nature and adapt ourselves to them.

What can be accomplished by such persistent endeavor is nowhere more strikingly shown than in the remarkable achievements of medical science and hygiene. That we are no longer impotent against pestilence and disease which formerly depopulated entire countries, that infant mortality has been reduced extraordinarily, that the average duration of human life has increased notwithstanding the exhausting struggle for existence, that we are able to trace most processes of disease from their first causes to their final stages and to influence their course prophylactically as well as therapeutically, are facts which of themselves must silence all objections to the legitimacy of the science of medicine, whether they be raised by fanatics on the subject of nature's manner and purpose of selection or by religious enthusiasts. Many an unsolved and apparently insoluble enigma still confronts us; our discernment of the course of disease

and of its remedies is by no means perfect, and we still must allow people to die without ascertainable cause; but not even those facts constitute valid arguments for the opponents of medical science.

The weakling alone is discouraged by failure. The physician never is apathetically resigned, but ceaselessly strives onward along the road which his desire to triumph over disease and suffering bids him take.

Special objections to psychotherapy may be raised. With a certain amount of justice it may be said this branch of therapeutics has not yet earned its right to recognition. It may be said that medicinal therapeutics, surgery, all physical means of treatment act by material effects which may be seen, felt, or recognized in some other way. It may be argued that the basis of the psychotherapist's work still is insecure, while the surgeon who removes a malignant growth, opens an abscess, sews up a wound, or ties a bleeding artery is acting in accordance with the requirements of exact science, and the physician who combats an infectious disease by means of the corresponding antitoxin, who reduces fever by a withdrawal of heat, who makes use of quinine in the treatment of malaria,

etc., is sustained by medical and physical laws, or, at any rate, by practical experience. It may be contended that in psychotherapy the material, the physical basis is wanting; that it appeals essentially to the idea, to the power of imagination, to belief; that it makes use of no other method than that of declaration; that it is comprehensible how the medicaments of the physician or the knife of the surgeon produce curative physical changes, but it seems entirely incomprehensible that bodily disorders which have defied other methods of treatment can be influenced by psychotherapy, by a simple declaration.

Such scepticism would be fully warranted were we to maintain that organic tissue changes can be done away with by means of psychic treatment. But, as we have shown before, psychotherapy can have for its object only the cure of functional diseases and functional symptoms, diseases of the imagination, which despite their immaterial basis are perceived as actual diseases. Still, psychotherapy bears no impress of the mystical as do the faith and mind cures of confused theorists. Its results, indeed, may be the same as those attributed to the waters of Lourdes or the holy coat of

Treves, but it does not ascribe them to miracles, to supernatural occurrences, but shows them to be in conformity with natural laws which enable us to understand the contraction of a muscle when it is stimulated by an electric current or the palpitation of the heart under the stress of emotion.

In the chapter which is to follow we shall show that ignorance or disregard of these laws of nature involves psychotherapy in precisely the same dangers as it does the practice of medicine in any form by the unqualified. Here it need merely be stated that psychotherapy is based on no other principles than those which must guide all therapeutic methods.

The same given causes under the same given conditions must always produce the same effects. Therein lies the justification for psychotherapy, if any outside its practical successes be demanded.

Certainly Christian Science, as well as all other forms of faith and prayer cures, is psychotherapy just as much as the latter may be looked on as cure by faith in that it is dependent on faith in the suggested idea. All suggestion remains ineffective in the absence of faith, in the absence of its acceptance by the patient. That it can, however, exert

most astounding influence on the functions of the body, when once it is firmly established in the brain, has already been shown by various significant examples. Is there any reason, then, why this influence of mind or imagination on the bodily functions should not be utilized therapeutically?

Scepticism is permissible only toward that form of psychotherapy which ascribes cures to a miracle, to a supposed response to prayer in the shape of supernatural intervention between man and the order of nature, with a suspension of causal laws. Later we shall discuss in detail the aberrations which have resulted from this pseudo-psychotherapy, which, on the one hand, claims to cure all diseases indiscriminately by means of faith, and, on the other, has a fundamental disregard for all of nature's remedies. Faith in any therapeutic procedure, when employed under conditions which the experienced physician recognizes as suitable for suggestive influence, is classed by scientific psychotherapy with the natural remedies. Scientific psychotherapy, moreover, differs from Christian Science in limiting itself to the use of suggestion only in suitable cases, at the same time allowing full latitude in every instance to any other method

of treatment and considering it thoroughly warrantable to reinforce the action of any medicinal agent by arousing a belief in its curative virtues.

The previously cited principle that the expectation of the occurrence of a certain physiological or psychological effect tends to bring about that effect becomes of practical import in the exercise of psychotherapy.

Recovery is what an invalid anticipates and hopes for. It is evident, therefore, that in psychotherapeutic treatment a belief in recovery is to be suggested above all else. As Moebius says, "Faith is the simple mental remedy, whether it is faith in recovery or faith in this or that curative procedure." No matter under what guise the suggestions which are to arouse or to augment this faith in recovery have been employed, it is always the anticipation of improvement which causes their beneficial action.

Daily life furnishes numerous examples of this palliative and curative influence of faith. How many minor ills are ameliorated by the mere assurance that they are of no import and will pass away? Is the mother's statement to her child suffering from headache that the pain soon will cease any-

thing but psychotherapy? Is not consolation in misfortune or in sickness also a remedy that acts through suggestion? Our friends comfort us in our physical and mental sufferings because they know that consolation lessens distress and ameliorates the condition of body and mind.

If the reassurance of a friend whom we know not to be competent in medical matters can produce alleviation in many diseased states through the suggestion which it carries, how much more potent must be the suggestion conveyed by the physician who wears the garb of authority! Should it astonish us if many remedies which the adept physician prescribes carry with them a suggestive influence in addition to their physiological one? The patient is anxiously intent upon carefully following every detail of the medical ordonnance; he counts each single drop, carefully adds and stirs the water, imbibes the mixture, and then awaits the improvement, which often sets in before there can be any actual remedial effect of the medicine, any question of its assimilation by the tissues of the body. Of course, it must not be thought that all remedies act by means of suggestion. The materia medica contains tested remedies so specific in

their action that such a supposition would be absurd.

Here again it is not out of place to lay stress on the fact that a reversal of any physiological drug action through suggestion, as, for instance, a sudorific effect from atropine or a laxative one by means of tannin, can never be produced. When all has been said, however, there still remain numerous remedies which, in all probability, carry with them simply a suggestive action. Otherwise, how could we understand the daily advocacy of new remedies, said to be of extraordinary efficiency? As a matter of fact, the early employment of such remedies is attended with unusual success; physician and patient are gratified that a specific has been found at last. Soon, however, that enthusiasm wanes; dispassionate discrimination takes its place and it is seen the efficiency of the remedy was due entirely to faith in its activity, and that both efficacy and faith had passed away simultaneously. Not only to many patent medicines and to the panegyrics of charlatans, whose cleverly worded advertisements create about the undiscerning public an atmosphere of suggestion, are such effects of faith due. It cannot be denied that critical and sceptical physi-

cians frequently are the victims of self-deception which also is sure to influence the public temporarily. It is clear, however, that no scientific and conscientious physician will prescribe, merely to produce a suggestive influence, a remedy of whose inefficacy he is convinced. Such action cannot be justified in any circumstances. Science should never prostitute itself to become the tool of wilful deception, even if it is of no importance to the patient whether his improvement be due to the remedy itself or to a belief in its curative virtues.

The domain of psychotherapy is ample without resorting to any such means. All the complaints due to actual disease, but which are magnified by mental processes which cannot be comprehended by the patient, all the functional disorders of neurasthenics, hysterics, etc., the many associated symptoms of organic disease due to fear and apprehension of future occurrences, to introspection and to erroneous deductions from readings of varied nature, properly belong in that domain, and there psychotherapy will find a fruitful and grateful field for the exercise of its influence.

C. Dangers of Psychotherapy

That psychotherapy has its dangers has already been stated. This may be understood easily if we but consider that treatment by suggestion is simply a part of general therapeutics. Just as the surgeon first must learn all about the operations which he is to perform and as the physician must know the toxic action of all drugs which he employs, so must the psychotherapist be well informed as to the numerous precautions which the practice of his branch entails. Every specialist at least must have such knowledge of his special branch as will enable him to make correct diagnoses and to institute proper treatment in extraordinary cases, and to do that with greater precision and certainty than can be expected of the general practitioner. What would be thought of a surgeon who is not thoroughly versed in topographical anatomy, or who is not master of the operative technique? What of the clinician who cannot differentiate a bronchial from a cardiac asthma? Similarly the psychotherapist has missed his vocation if he is not the possessor, in addition to a good general medical education, of special knowledge of the psycho-physiological

laws, of the functions of the mind and the nervous system and their reciprocal relations under physiological as well as pathological conditions.

All dangers which may possibly follow the employment of treatment by suggestion are attributable, without exception, to incapability or neglect on the part of the psychotherapist. Morphine in the hand of the physician is a remedial blessing, in that of an inexperienced layman or a criminal a lethal poison. Psychotherapy when employed by the incompetent becomes a curse instead of a blessing. For the psychotherapist who is not properly schooled, the practice of suggestive therapeutics will be nothing more than uncertain and haphazard experimentation in the course of which, when favored by chance, he may occasionally obtain a certain degree of success. As a rule, however, he will cause only harm.

The greatest danger lies in making an error in diagnosis, in a failure to recognize the disease actually existing. The scientifically trained physician is only exceptionally liable to err in this manner; the lay practitioner, on the other hand, cannot reasonably be expected to possess any accurate knowledge of the complicated conditions met with

in disease, or any capability of differentiating between organic and functional disorders, and, therefore, will usually be in error. Such error will cause the patient to conceive himself to be afflicted with the disease which has been ascribed to him. Thereafter it will be easy for him to obtain information concerning the symptoms of that disease through popular scientific writings, and, provided his belief in the faulty diagnosis be sufficiently strong, he will not fail to discover those very symptoms in himself. Meanwhile the real disease remains uncared for, and, the proper moment for therapeutic intervention having passed, may become refractory to therapeutic influence of any kind. The damage thus has been increased twofold. Not only has the patient not been freed from his primary trouble—the malady, on the contrary, having been aggravated—but he also has had thrust upon him another which, albeit one of the imagination, is experienced as an actual disease.

These remarks bear particularly upon the adherents of Christian Science and upon visionaries of other kinds who, as a matter of principle, disparage the employment of all therapeutics and, looking on disease as a visitation, perhaps a pun-

ishment for sin, expect a cure to be wrought indiscriminately and solely through faith and prayer. It goes without saying that for such persons a correct diagnosis is not of the slightest import. Let it be stated parenthetically, however, that the majority of church congregations, irrespective of creed, have taken a stand against believers in such mistakes, and have expressly recognized the obligation to employ the remedies furnished by science, instead of awaiting hopefully the intervention of miraculous happenings.

Since in psychotherapy no instrument or chemical substance is used, but simply assertions which may be considered entirely harmless, it may be asked how can there be any danger at all in the use of suggestive treatment, no matter how incorrectly employed? It is precisely in those so-called harmless assertions that the danger lies. Adopted by the person who is being treated, they become fixed in his brain, are transformed into perceptions, and impulses of the will, and thus under certain conditions may develop into a controlling power over the entire personality, and, through the resultant influences on the functions of the body, may carry in their wake disorders which have not been present before.

Special precautions are required in the use of hypnotism. Incorrect employment of it may bring about permanent harm. Through hypnosis the impressionability for suggestive influence becomes increased. The person in that state, consequently, subordinates his will to that of the hypnotist more readily than during the waking state. The object of all psychotherapy should be the strengthening of the patient's will. When that object has been defeated and the will power enfeebled, the fault lies in the method employed. True, the hypnotized subject can never become a volitionless automaton. No hypnotist can coerce him to commit deeds which are repugnant to his fundamental character and which he could not have been induced to commit during the waking state. Still, a conscienceless hypnotist can designedly and permanently weaken the will of a patient and place him in a condition of abject dependence in order to take advantage of him for selfish ends. Hysterics who have been frequently hypnotized acquire an augmented suggestibility, not only in their relations to the hypnotist, but to every one else, so that even in the ordinary occurrences of every-day life their thoughts, feelings, and actions may be swayed

easily. Such subordination of the will must be prevented under all circumstances, for the only justifiable object of suggestion and hypnosis must be to effect a cure. Once that object is ignored all dangers incident to psychotherapy will surely arise.

In certain conditions it may be excusable for a physician to institute hypnotic experiments for purposes of study, and that will be justifiable if care is taken to exclude all harmful influences. But the use of hypnotism can be characterized only as deprecable and unwarrantable when, as has been done, a neurasthenic patient is led through suggestion to have the experience of a raging storm, during which the house is struck by lightning, and, through reacting to such suggestions as though to an actual occurrence, is overcome by terror from which he never recovers; or when, for the purpose of studying post-hypnotic phenomena, the hypnotist arouses sense deceptions which leave the patient in a state of fright.

Among the dangers of hypnosis mentioned by many authors must be classed the artificial production of hysteria. Others claim, because of their observations, that hypnotism is responsible for disorders of intelligence, for nervousness and head-

aches. Still others contend that hypnosis has been the productive cause of harmful auto-suggestions, or that the suggestions implanted during the hypnosis have a tendency to recur during the waking state, even without the special command of the hypnotist.

All these ill effects and dangers, however, are rocks on which none but the inexperienced are wrecked, while the trained and adept psychotherapist, he who but rarely makes use of hypnotism, knows how to avoid them. For the psychotherapist who practices with a thoroughly conscientious observance of the responsibilities involved, suggestion during hypnosis or during the waking state always represents simply a curative procedure, the dangers of which fade into thin air when the art of diagnosis is combined with the knowledge of therapeutic laws.

D. Christian Science, Faith and Prayer Cures

Twenty centuries of progress in the training of thought and in the discernment of nature's processes has not been sufficient to free mankind of the idea that the omnipotence of God must disclose itself, as well as in many other ways, by a constant regulation of the functions of the human

body in health and disease. And wherever we find that idea firmly implanted we also find the outcropping of superstition, with the wonder cures dependent on it. Hence, even in this era of enlightenment and precise, unprejudiced investigation, we find the most pregnant scepticism and the most crass superstition existing side by side. That condition simply proves that history repeats itself.

In a preceding chapter we spoke of the temple sleep, a function which two or three centuries before the Hippocratic era—at a time, therefore, when Greek culture was dominated by theistic principles—represented a factor in the art of medicine the employment of which was fully warranted. As Magnus very justly states, this temple sleep must be looked on as evidence of a faith notable particularly for the depth and fervor of the sentiment which prompted it; of a faith, it is true, which was artless and childlike, but always touching. At that time this function contained as yet no trace of superstition. It represented the pure and uncorrupted expression of the belief then current that human art was futile against all disease, and that help could be had only from the

gods, who were credited with regulating and, in fact, producing even the smallest detail of mundane occurrences.

An abrupt change in that situation came when medicine perceived that the manifestations of disease were not the results of supernatural interference with the functions of the human body, but disturbances of bodily life produced by terrestrial, natural factors. That point of view was first defended in the writings of Hippocrates, and thereafter the temple sleep, which previously might have been excusable because of the lack of proper understanding of the occurrences of nature, lost all right of being. The more intelligent comprehension of those occurrences should have caused the temple sleep to disappear absolutely from the art of medicine; but, as that did not occur, it necessarily degenerated into a superstitious imposture. No one but the priests can be blamed for this unfortunate condition. They, above all others, should have directed into proper channels the beliefs of the sick and the infirm who, in childlike piousness, crowded the temples in search of health. By not doing that, and by trying in every possible way to maintain among the masses the old belief in the thera-

peutic capabilities of the gods, the priests made themselves disseminators and allies of superstition. With the decline of antique culture and religion, the temple sleep by no means disappeared; it merely became altered in form and continued to persist, under the name of church sleep, as belief in the miraculous powers of saints and relics, and ultimately as the Christian Science of modern times.

These facts are of great importance in making the ultimate estimate of Christian Science, faith and prayer cures, because a correct decision must be based on the question whether those cults are governed by a lack of appreciation of the true facts, or, knowing them, are the purveyors of wilful deception.

Notwithstanding the belief in the potency of the temple sleep was thoroughly shaken as early as the sixth century before the Christian era, the priests were untiring in their endeavors constantly to reinforce this credence by all manner of superstitious practices. The sixth marble votive tablet found in the Æsculapian sanctuary at Epidaurus gives evidence of the kind of miraculous occurrences reported by the priests. It was their custom to record on such tablets, reports of the cures which

took place in their sanctuaries. It is narrated on this sixth tablet that a blind man, Hermon by name, had regained his sight through sleep in the temple. But, it seems, Hermon was rather parsimonious, for he departed without showing, in coin of the realm, his appreciation of the miracle which had befallen him. Doubtless this ingratitude greatly offended the god, for he forthwith deprived Hermon of his vision again. Another temple sleep, together with an adequate monetary contribution, was required to mollify him and induce him once more to restore Hermon's sight.

Let us take note here of various instances which Magnus has critically recorded in his book on superstition in medicine. Mummolus, who was sent by King Theudebert as ambassador to Emperor Justinian (527–565 A. D.), was much harassed by pains due to stone in the bladder, and on the ambassadorial journey suffered from such an attack. He must have been in great agony, for he made his will without delay. He then was advised to spend a night of sleep in the church of St. Andrew at Patras, where the saint then was accomplishing most wonderful cures. Mummolus, racked by pain and fever, had his bed made on the stone

tiles of the sanctuary and there awaited further happenings. At midnight the sick man suddenly was awakened by a strong desire to urinate, and soon passed a stone of such size that it fell with a ringing sound into the urinary vessel. From that hour Mummolus, who only shortly before had despaired of life, was restored to health, and soon afterward he started on his homeward journey.

Fedamia, a woman living in Brioude, the capital of the modern department Haute Loire in France, had been paralyzed for years. The church of St. Julian then enjoyed a large reputation in Brioude, and, as Fedamia was penniless, her relatives took her there so that, even if she could not regain her health, she could at least earn some money by church beggary. For eighteen years she followed that pursuit. Then, on a Sunday night, when she was sleeping in the colonnade adjoining the church, there appeared a man who took her by the hand and led her to the tomb of St. Julian. There she prayed most devoutly, and while doing so she felt an actual load fall from her limbs. All this, of course, happened in a dream, but when the invalid awoke she was well again and, to the astonishment of the assembled people, was able to walk

to the grave of the saint as she prayed aloud. A blind deaf-mute named Amagildus also tested the sleep in the Church of St. Julian in Brioude, but it seems the saint was not always pliant to the wishes of the sick. Amagildus did not have to spend eighteen years in the basilica, but he did have to sleep an entire year in the colonnade of the church ere the curative power of the martyr freed him from his sufferings.

Veranus, the slave of a priest, had so severe an attack of gout that for a whole year he was deprived of all power of motion. His master then vowed to consecrate him to the sacerdotal order provided St. Martin would heal him. The sick man was carried into the church and laid at the feet of the statue of the saint. For five full days there was no change in the condition of the sufferer. On the sixth day a man appeared to the slave and stretched his leg. Frightened, he jumped up, when lo! he was cured. And for many a year he served St. Martin as priest.

A most noteworthy cure was effected for the German Emperor, Henry the Second (1002–1024), called the saint. He was suffering greatly from vesical calculi, and for that reason took refuge in

the Italian monastery, Monte Cassino, which then stood in marked medical renown. The monks of Monte Cassino, who usually were most expert in such cases, seem to have had no confidence, however, in their medical ability when the emperor came to them as a patient, for they withheld from him all mundane medicine and relegated him to the cure of heaven—more especially to the healing power of St. Benedict. This saint visited the sick man when he was asleep in the monastery, performed the operation, and departed after having placed in the patient's hand the stone which he had removed from the bladder. Certainly this visit of the saint was more in keeping with the dignity of the patient than if the operation had been left to mere mortal hands, even if they were those of pious and learned monks.

Alpinus, Count of Tours, suffered for years from an affection of the foot, so all joy in life was gone and he remained bedridden, sleepless and unable to eat. Repeatedly he had implored St. Martin to heal him, but in vain. Finally, however, the Count sank into a deep sleep during which St. Martin came to him and made the sign of the cross over the affected foot. At once all pain disappeared.

Alpinus was restored to health and able to leave his couch.

On another occasion St. Martin of Tours appeared to a woman who was deprived of the use of her hands as a result of contraction of the fingers. These the saint extended forcibly so as to tear the contractured tendons. During this operation, strange to say, the saint was clad in purple.

Distinct specialistic tendencies and qualifications were attributed to certain saints. St. Anna, for instance, practised opthalmology; St. Judas was adept in the treatment of coughs; St. Valentine excelled in treating falling sickness (epilepsy), and St. Catherine of Sienna in treating the plague. Not even the cattle were neglected, for St. Roch of Montpellier was distinguished especially on account of his veterinary activities.

Various means were used for obtaining the aid of one or the other of these saints. The most simple, probably, was to attend mass in a local church and to offer a sacrifice to the saint. Less easy was a pilgrimage to the shrine of this or that saint of medical renown. Such a pilgrimage was undertaken usually on the birthday of the saintly physician, for the saint on that day seemed to be

specially disposed for the practice of medicine. At any rate, the Chronicles report that on those days the most difficult cases were successfully managed in large numbers. As we have seen, the saints often exhibited no haste to exercise their medical dexterity, occasionally permitting patients to await their help for years. For that reason the church inaugurated the following very practical and valuable plan. Adjoining the church spacious accommodations were installed for the reception of patients. There those in search of health could obtain food and shelter and peacefully await the intervention of divine help. This arrangement was of especial value for the many patients who retained their health only so long as they remained close to the saint but had relapses as soon as they returned to their homes.

On the whole, the church sleep, together with the prolonged sojourn in the church shelters, which often were like hospitals, was rather inconvenient, especially because of the difficulties and dangers incident to all distance travel in the Middle Ages. It became necessary, therefore, to conceive a method by which the medical aid of the saints could be brought within the reach of the afflicted at all times.

Relic worship was the method chosen. The bodies of martyrs who had given up their lives for Christianity or of saints especially distinguished for their piety were believed to be endowed with special miraculous power. Furthermore, it was believed that power had been transmitted by the earthly remains of martyr and saint to all objects with which they had been associated during life. These objects or relics in turn were able to exercise similar miraculous power over any other object brought into contact with them. It was easy to send such objects all over the world and thereby make the original relic indirectly accessible even to those invalids who were unable to undertake a long pilgrimage.

Special healing virtues, for instance, were ascribed to the water with which the tombs of the saints were cleansed at Easter; any sick person washed with such liquid soon would recover, it was believed. A certain Countess Eborin was so ill that she was convinced her last hour had come. She was transported to the church of St. Martin at Tours and there was washed thoroughly with water dirtied from being used on the saint's tomb. The expectation of cure did not fail to produce

its effect, for the Countess was well from that moment.

It seems, however, that the medical achievements of the saints did not gain the confidence of the laity nor of the priests to such an extent that the professional doctor was renounced entirely. Even St. Gregory of Tours, whose writings contain an endless fund of knowledge regarding the miraculous cures achieved by the saints, sought help, when he became sick, through remedies administered by a terrestrial physician in conjunction with the divine remedies. Generally, however, in order not to weaken the wide faith in miracles, and also, perhaps, to prevent curtailment of the church's monetary revenues, the priests were studiedly cautious to ascribe all recoveries of the sick directly or indirectly to the saints as intermediaries of the Almighty, even when the cures were due to natural causes.

In all these examples from mediæval times, to which could be added numberless instances from the present, it may be seen without difficulty that the problem involved was one of functional disorder, which faded away under the influence of the power of the imagination, represented by a belief

in miracles; or, admitting some of the cases to have been of an organic nature, that the happy results were achieved by natural medical or surgical means associated with dexterous trickery, possibly with the best of intentions, through which the patient was kept in ignorance of the true character of the help which he received. There can be no doubt many Christian priests of the Middle Ages, as well as their colleagues in the Greek temples, did not disdain to employ such conscious deceptions, for it is certain they were by no means ignorant of the natural causes of disease and of the processes of recovery. Let us not forget that, during the Middle Ages, the Christian monasteries not only were the disseminators of humane culture, but also gave protection and encouragement of the highest order especially to medicine. It may even be said without exaggeration that, at certain periods of the Middle Ages, Christian monasteries bore the same relation to progress in medicine as later did the universities. Not only did the Christian monks foster nursing and medical treatment of the sick, but they also devoted much time to the scientific study of medicine; and, what is more important, they were thoroughly conversant with the medical

classicists of antiquity, Hippocrates, Galen and others, who had demonstrated convincingly the irrelevancy of supernatural occurrences to the causation, and of the temple sleep to the cure of disease. All medical culture, in short, was confined during that period to the monasteries, which furnished a far larger proportion of members of the medical profession than did the laity.

In that condition of affairs it might have been expected the monks and secular priests would use their medical knowledge to combat the abuses which were perpetrated by the use of the bones and the names of saints. But, neither during the Middle Ages nor subsequently, did they volunteer to correct those abuses. Subordinating their better knowledge and moral sense, they not only failed to instruct the people correctly, but in countless instances allowed patients to believe cures had been wrought by this or that saint although, as a matter of fact, it was the monks themselves who brought about the altered state of health.

We must not, however, disregard the fact that the mediæval monks and priests were quite as much a product of their times as we modern people are the product of ours. The Middle Ages having

been the period of miracles, demons, and witches, the clinicians of those times naturally had a different conception of miracle and demon belief than we. Through their devout and fervent faith in the omnipotence of God, the Christians of those times became convinced He could and did at all times manifest His omnipotence by altering the course of natural processes and terrestrial happenings. Alterations of nature manifestations, therefore, did not impress the mediæval Christians as being miracles, for, as they comprehended it, one and the same phenomenon of nature could occur in one way to-day, and in another way to-morrow, in accordance with God's pleasure. To them it was quite as incomprehensible that all manifestations of nature should be dependent on inalterable laws, uncontrolled by any mediation of the supernatural, as to-day it is inconceivable to us that God could or would at any moment set aside a law of nature to benefit one or another of us mortals. For that reason the priests and laymen of eras rife in the belief of medical miracles cannot be judged by the standards which we apply to-day to those who still believe in the occurrence of medico-scientific wonders.

Owing to the conditions then prevailing, many a Christian monk or priest may have vacillated between the demands of faith and those made upon him by his medical enlightenment. That the pillars of the church were not exempt from such frailty is shown by the case of Gregory of Tours, who, as previously mentioned, endeavored to cure the ills of the body not only with remedies supplied by the grace of God, but also with medicaments of the professional pharmacy. Certainly in an era characterized by credulity and faith in miracles the dominant belief in God's interventional powers made any opposition to belief in them exceedingly different from what it is to-day. It may well be, therefore, that many an enlightened monk or priest, weary of combating the people's thirst for celestial medicine, sacrificed his scientific convictions to the fantasies of over-wrought faith.

Some consideration, therefore, may be due to the attitude of monks and priests of the Middle Ages, but there is not the slightest excuse for the present day zealots who advocate miracle, faith, and prayer cures. This is true especially because medical knowledge, the appreciation of the natural laws which govern the production and

cure of disease, has become so complete and exact that ignorance, which has been so well called the culture medium of faith, can no longer be professed. When it is recalled that Hippocrates, notwithstanding the comparative deficiency of his medical knowledge, declared his opposition to the assumption that God himself, unhampered by natural laws, regulated all terrestrial manifestations, how is it possible for any person of intelligence to contend to-day, simply because of our inability to control many processes of disease, that there are enigmatical powers which can make us sick or well, according to wish and will?

It is comprehensible that people should have appealed to the "unknown God" for help in all afflictions of the body at a time when, through ignorance, they believed themselves at the mercy of all kinds of unknown powers. But to-day, as we are able to recognize the origin and foretell the course of almost every disease and as we have at our command adequate natural remedies, there certainly can be no reason for having recourse to supernatural aid. The truth of that is all the more evident because our knowledge of pathogenesis and therapeutics, as well as of preventive

medicine, is daily increasing and becoming more trustworthy.

Stress also must be laid on the fact that, in this century of mechanico-physical conception of the laws of nature, when all scientific knowledge quickly becomes assimilated by the mass of the people, the question of making concessions to popular belief is not involved. Popular belief to-day does not look for the production of miracles. Nevertheless we observe daily, not only among the less cultured in smaller villages, but also among the enlightened and usually incredulous people of our large cities, that Christian Science is winning enthusiastic supporters. Can this deplorable fact be attributed to anything but a misguided religious sentiment?

Many instructive instances from most recent times might be adduced to demonstrate the extremes to which an over-wrought religious feeling, lacking in the counterpoise which a mechanico-physical conception of nature gives, may lead. Typical examples are Mrs. Eddy's Christian Science, John Alexander Dowie's Christian General Church in Zion, and the Emmanuel Movement.

The system of Mrs. Eddy, an absurd jumble

of undigested scraps of philosophy, of distorted medical observations and of crass errors of judgment, is based on the belief that disease has no material basis, but is due entirely to certain states of mind. This conception, which has been borrowed from a natural philosophy long ago discarded, makes the employment of physicians and medicines superfluous, the treatment of the sick being assigned to persons able to teach the patient how to concentrate his mind upon the spiritual or God-like principle which dwells within him.

Mrs. Mary Baker Patterson, afterward Mrs. Eddy, after having had a wondrous vision, which later "proved to be God-given by healing the lame and the blind and by raising the dying," verified her vision because, proceeding in accordance with it, she said, she had "prevented disease, preserved and restored health, healed chronic as well as acute ailments in their severest forms, elongated shortened limbs, relaxed rigid muscles, restored decaying bones to a healthy condition, brought back the lost substances of the lungs and caused them to resume their proper functions."

Eddyism contains several so-called maxims from which the student is not allowed to depart. These

fundamental propositions are: God is all in all, God is Mind, God is good; therefore, as God is all in all and there is nothing but God, or Mind, and if God is good, there can be nothing which is not good. As God is good, He does not wish His creatures to suffer, and, as suffering is not dependent on Mind, *i. e.*, God, but on matter, therefore it can arise only through sin. Only when matter has gained control of mind through sin can the suffering of matter be transmitted to the mind. Cure, therefore, can consist only in mind regaining sovereignty over matter. This ascendancy of mind over matter, or re-union with God, which had been disturbed through sin, can be re-established through prayer. Then mind, the only reality, conquers matter, which has no reality, but exists merely in our imaginations. All our suffering is at an end when mind has emancipated itself from the false notion of the reality of matter and its dependent ills.

These absurd propositions, devoid of the least semblance of science, are noteworthy in that they mark the line of contrast between Christian Science and other systems of faith and prayer cures. All the other systems furnish more or less evidence

of belief in the existence of disease as a punishment for our sins, and as a divine visitation for our moral elevation, but in Christian Science that conception is entirely absent. The reality of suffering being in no way recognized, disease can serve no ethical purpose.

That any person ignorant of the laws of reasoning and unburdened by knowledge of the positive facts should produce matter so confused and unrelated as does Mrs. Eddy in Christian Science should cause us no astonishment. History shows that at all times people of all classes have devised and expounded nonsense of the most intricate kind. That the view of Mrs. Eddy should have found support among people of all grades of intelligence to so great an extent that governing bodies felt themselves called on to intervene, and this at a time when the progress of the natural sciences must have forced some light into even the dullest brain, is probably the most interesting point in connection with the entire subject. In a critical review of the Eddy system, Magnus says the historian really should be astonished by nothing, for, no matter in what field he conducts his investigations, he will again and again find human stupidity and igno-

rance constituting a power superior to cultural factors of every kind. A discussion of the details of the Eddy system at great length will be unnecessary; only two points are worth special consideration.

First we would note that there is no difference of moment between the miracle cures of the Middle Ages and Christian Science. In the former it was the saints who restored the sick to health, but they did so not through any superior qualifications of their own, but through miraculous gifts bestowed on them directly by God. They were mere intermediaries between the patient and God, through whose omnipotence was caused sickness or health, according to His will. Mrs. Eddy, on the contrary, scorns such intermediation and advises her adherents to appeal directly to God Himself. In one way or another it is made to appear that any aid which comes to a sufferer is superhuman, supernatural, even in those instances where it must be perfectly obvious recovery is certain through entirely natural means.

Secondly, we cannot refrain from reiterating what Mary Platt Parmele wisely says, that Christian Science is neither Christian nor science. After all we have said, no demonstration is needed

to prove that it is not a science, and that it and science have nothing in common. Science is the recognition and explanation of facts in nature and history. Since Eddyism disdains to give any consideration to facts, even to those induced from experience, but bases its doctrines entirely on sentiment and fantasy, it proves itself to be the pure product of an imagination led astray by the misinterpreted readings of its originator.

But, some one may say, at least this system must be recognized as Christian. Certainly not! For one may be a devout Christian without expecting God to reverse or annul the order of nature.

If it be assumed God is the Creator and Maintainer of all things, it must follow that all physical and chemical remedies are of His giving. It may not be inconsistent with the religious sentiment of the present day to believe that, in certain conditions, God might interfere with the methodical course of nature,—that is to say, might perform a miracle,—but it cannot be consistent with sound religious sentiment to assume that He would grant such supernatural aid when we are able to help ourselves by means of natural remedies. Is it not disrespect to the Maker of all if one declines to employ

the remedies at his disposal in order to rely on the supernatural? There is nothing which to-day justifies the belief, pardonable in an era of ignorance, that the physical welfare of each individual is guarded day and night by the Creator of all. If for no other reason, that assumption is refuted by the fact that in all times humanity has been dependent on itself in its battle against disease and pestilence and has had to learn how to protect itself against such afflictions. Inasmuch as Christian Science refuses to recognize the self-aid which natural forces place at our disposal in sickness, this "science" certainly can lay no valid claim to the designation "Christian."

The same must be said of John Alexander Dowie's Christian General Church in Zion. Dowie, it is true, must be judged from a stand-point different from the one applied to Mrs. Eddy. He is in accord with her only in the complete rejection of all professional medical treatment, whether by means of drugs or surgical intervention. But he and she arrived at this conclusion in entirely different ways. A faith pathetic in its artlessness led him to accept literally all the expressions in the Old and the New Testament. Because the Book

of Exodus, Chapter XV, verse 26, expressly says, "For I am the Lord that healeth thee," and because in the Epistle of James, Chapter V, verses 14–16, prayer is recommended as the best cure for disease, Dowie decides to employ prayer alone in the treatment of all forms of physical disorder. Even in surgical cases he supposes prayer to be more efficacious than the surgeon's art. In that Dowie takes a stand not different from that of the earliest Christians. Such treatment of disease by prayer is related closely to the idea that all bodily sufferings are divine visitations, intended to impress man with God's anger. That conception of pathological processes may well be termed primeval. How ancient it is is shown by the fact it is met with among the Egyptians; in Exodus we read how the Lord visited on Pharaoh and his people all kinds of afflictions, such as pestilence, black pox, and death of the first born. This view was adopted by Christianity and in the Middle Ages developed extraordinarily in form and dimensions. Every disease which occurred in epidemic form then was looked on as a visitation, as a corrective rod which God wielded over humanity. Peter Paladin, the pious Bishop of Zealand, assures us

that the "English Sweat," that dreadful pestilence which devastated Europe five times between 1486 and 1537, was sent by God in anger at the inordinate desire of the people of that time for enjoyment and personal adornment.

Both Eddyism and Dowieism start from the assumption that disease can be cured only through re-establishment of community with God by means of prayer. Both systems seek one end, but Dowie interprets the Bible text literally, while Mrs. Eddy combines it with all sorts of fantastic ideas from Indian philosophy, conceiving the entire physical world as an error, as existing merely in our imaginations.

Finally a word about the adherents of the so-called Emmanuel Movement. A few years ago the Rev. Dr. Worcester, of Emmanuel Church in Boston, inaugurated a movement which was brought to public notice through the daily press and other periodicals—a movement the thin disguise of which allows the features of Christian Science to be recognized easily. Still, the position of the adherents of Dr. Worcester is different from that of Mrs. Eddy in that they do not directly renounce medical treatment. They admit that organic

changes of the body cannot be cured by prayer, and therefore take the precaution to have a correct diagnosis made for them by professional physicians. Making a suitable selection of cases in that way, they leave to the doctors those patients suffering from organic disease, while those suffering exclusively from functional disorder are subjected to cure by means of prayer. This movement really originated in England several years ago, but did not meet much success. Even here it has not grown and spread as at first it was expected to.

To recapitulate briefly: We have learned that, through psychotherapy the perception of pain may be suppressed to a certain extent, appetite and digestive functions regulated, heart action quickened or retarded. We know that, on account of the tendency of the organism to complete a process which is anticipated, hysterical paralyses, as well as certain idiosyncrasies, may be removed by means of suggestion. We also know that suggestion may be employed with success in all forms of disease which manifest themselves by functional disorder and functional symptoms. If, then, it be said it is immaterial whether these effects are produced through prayer or through psychotherapy, the reply

must be that, although, objectively considered, the result may be the same in either case, subjectively the psychotherapist works with creditable methods, while the faith and prayer curist is the victim of self-deception in that he attributes to a miraculous influence the beneficial results attained by natural means, through the power of the imagination. What is of the greatest moment, however, is the sacrifice of many lives through the renunciation of medical treatment, which is characteristic of Christian Science—lives which could have been saved had there been an opportune recognition of the organic disease which led to their extinction, and which was quite as unamenable to psychotherapy as to religious treatment.

Therein, in my opinion, rests the moral culpability and the criminal responsibility of all faith and prayer healers. They wilfully exploit a superstition, and against such procedure the sick and the infirm must be protected.

E. The Personality of the Physician

The statement of a well-known clinician that disease is cured not by the remedy but by the physician must be accepted *cum grano salis*. The

kernel of truth which it contains is that the personality of the physician exerts an extraordinary influence on the efficiency of therapeutic procedures. This is true particularly in psychotherapy, where use is made of no material remedy but of mere assertion, and where, therefore, signal confidence in the physician's powers is a prerequisite. Hence, certain qualities must be possessed by the psychotherapist which are not necessary for the practice of other branches of medicine. Above all, the practice of psychotherapy requires special preparation; absolute essentials are a theoretic knowledge of neurology and psychology, a practical knowledge of the general clinical and anatomical peculiarities, and a special knowledge of all the details of functional disorders and functional symptoms. Psychotherapy is a sub-division of neurology and psychiatry. Only the trained neurologist and the psychiatrist, therefore, are qualified to practise psychotherapy; but, because of the mutational relations which connect all branches of medicine, even they can do so with success only if they are experienced in all other branches of medicine as well. This is so, if for no other reason, because the cases most amenable to psychic treatment, the

functional ones, often do not present such pronounced symptoms as would make it possible for them to be recognized at once. An error in diagnosis between organic disease and functional disease is one to which the inexperienced physician is easily exposed; and, of course, without correct diagnosis there can be no proper treatment. Only that physician who is in constant touch with general medicine is qualified for the practice of psychotherapy; only he who is able to exclude inappropriate cases from psychic treatment will save himself and his patients from disappointment.

Since, therefore, it is certain that not every physician, no matter how efficient he may be in his own branch, will be a good psychotherapist, it must follow that certain attributes are required for the practice of psychic treatment which need not be possessed by the surgeon, the general practitioner or the specialist in any particular branch of practise. This brings us to a consideration of the most characteristic difference between the practice of psychotherapy and that of the other specialties in medicine. For the recognition of all diseases presenting distinct objective manifestations, whether these be elicited by means of percussion or auscultation, or

by microscopical, chemical, radiographic, or electrical examination, no understanding between physician and patient actually is necessary. The fact that a patient is unconscious, or is a deaf mute, or speaks a language unknown to the physician need not preclude the possibility of arriving at a correct diagnosis or instituting the proper treatment. Without having to ask a single question, the physician can recognize a pneumonia, an organic disease of the heart or the kidneys, diphtheria, fractures, dislocations, etc.

In psychotherapy, on the other hand, everything, including diagnosis and treatment, depends on a proper understanding between physician and patient. The physician must be able to follow the train of thought and the emotions of children and adults, of the cultured and the uncultured, of the rich and the poor. If their ways of thinking and feeling be strange to him, how can he gain the confidence of his patients, or elicit the frequently abstruse history of their disease, or give them proper instructions? In psychotherapy, even when combined with other forms of treatment, it is the word which counts. To secure the acceptance of this word, to effect receptive adoption of his suggestions

by patients of the most varied degrees of education and refinement, the psychotherapist, more than other physicians, must possess a high degree of knowledge of human character and vast experience of life. Stress must be laid, too, on the ethical qualification of the physician. Not only must he understand the patient, but he must feel with him. Golden words are these of Delboeuf:

"When I am with a patient, deep compassion for his sickness overcomes me. When he suffers I partake of his pains, and when he weeps it moves me to tears. Between him and me there exists a common tie. Is it not this sympathy which makes it seem, when I talk to him, as though I were talking to myself, and is it not this same sympathy which makes him believe when I am talking, that he hears himself talking? Is not this compassion the secret of those who are successful comforters in sufferings which resemble their own?"

Cold, heartless, and emotionless egotists can neither comfort nor suggest successfully. Only forceful, sensitive, impressionable natures, themselves easily influenced by the sufferings of others, are able to exert a psychotherapeutic influence. Delboeuf's view that psychotherapy presupposes

the existence of a special sort of sensibility in the physician, and that it is the patient who first acts psychically on the physician, is perfectly correct. It is a fact that the manner in which the patient acts toward the physician is quite as important a factor in successful psychic treatment as is the demeanor of the physician himself. Where there is no psychic contact, the enthusiasm, the joy in one's work, becomes toned down. Hence it is this psychic contact which plays the determining rôle in psychotherapy. Without it medicines may be administered and surgical operations performed effectively, but successful suggestions cannot be implanted. No matter how calmly the physician may listen to the exaggerated complaints of hysterical patients, he knows the exaggeration is not simulation, and the patients actually suffer even if the existence of any disorder cannot be demonstrated objectively. In his therapeutic dispensation there can be but one governing law for the physician, and that is that when a patient believes himself to be suffering, and asks for help, he actually is suffering, and needs that help.

Wherever this psychic contact evolved from sympathy, which we have designated as the most im-

portant factor in suggestive treatment, is present, it will not be difficult for the physician to extend that measure of tranquility and patience which the nature of psychotherapy demands. This very demand, in fact, makes the practice of suggestive therapeutics impossible for many physicians. Time and patience are factors of the greatest importance. To listen to the never-ending complaints of many neurasthenic and hysterical patients is always a tax on both time and patience, but he who tries to hurry his patient, he who receives these complaints restlessly, without interest, or even with a hint the complaints are foolish or imaginary, will never achieve the slightest success in this form of treatment.

Nervous, excitable persons are particularly unadapted as psychotherapists, for the ability to concentrate his thoughts is necessary not only for the patient who is to be influenced, but also for the physician who desires his suggestion to be adopted. Similarly, on the other hand, the phlegmatic person will have but slight propensity for so arduous a task as suggestive or hypnotic treatment, for his words will lack that force which is necessary to impress the truth of his assertions on the patient.

Above all, the physician must be imbued with the truth of his own statements, for then self-confidence and surety of demeanor must follow.

He who wavers and doubts his own capabilities, he who does not himself believe in the effectiveness of psychic treatment, will never gain the confidence of his patients. I cannot agree with Struempell in his contention that the psychotherapist, and especially the hypnotist, must possess dramatic talent to produce a more marked impression and to conceal his own misgivings. There should be no want of confidence, no doubt in one's self, which may need covering. Of course, it is an advantage to the physician to have a voice which is tender and agreeable. Delboeuf mentions the favorable impression which the pleasant, convincing tone of Liébault's voice made on him. But, after all, the means of expression which the physician uses, whether these be words or gestures, must harmonize with his innermost conviction. Where that harmony is wanting, the successful practice of psychic therapeutics is impossible. It would almost seem the true psychotherapist is born, not made, and yet it cannot be denied that practice and experience are essential for the development of this natural dis-

position, and for the fixation of that confidence in one's powers on which success depends. The psychotherapist who is the fortunate possessor of natural and acquired qualifications cannot fail to cull the fruits of conscientious endeavor.

F. The Personality of the Patient

Emphasis has been laid repeatedly on the fact that it is in the field of functional disorder that the most brilliant successes of psychotherapy are achieved. All affections which have been produced by psychic influence, the force of idea or imagination, may also be set aside by psychic means. The main occupation of the psychotherapist, therefore, will be the treatment of neurasthenics and hysterics. Of these, according to the opinion of the majority of writers, those most easily influenced are children and other persons who are not given to independent thought and action, or, to put it in another way, who are accustomed to obey orders promptly, and who have great respect for authority.

Still, intelligence, will power, and strength of character also constitute important factors in suggestive susceptibility. Sceptics, persons in whom

the spirit of contradiction is strong, materialists, and those who are inclined to be sarcastic, are not influenced easily. They are insistent upon explication, and they criticize or oppose any method of treatment if they do not at once appreciate its efficacy. In their cases, hypnosis is the only method worthy of trial, for this sleep-like state excludes, or at any rate curtails, the force of counteracting objections. On the other hand, idealists, enthusiasts, people who are emotional and impressionable, are most easily influenced by psychic means. This is probably the reason why, according to Obersteiner, Moll, and other authors, people who are strongly affected and emotionally excited by music are good hypnotic subjects.

Real insanities, as we have seen, cannot be beneficially influenced by means of psychic treatment. *A priori* it would seem that precisely that want of critical acumen which forms so great a contrast between the thoughts and feelings of the paranoiac, the paretic, etc., and those of a healthy mind would be markedly propitious for psychotherapic action. But if we remember that this lack of discrimination, dependent as it is on actual disease of the brain, cannot be corrected so long as the tissue

changes or circulatory conditions which are present render an orderly association of ideas impossible, this apparent contradiction, that insanity and psychotherapy are incompatible, can no longer astonish even the mind of the layman. Ideas of grandeur, hallucinations, etc., when once fixed in the brain, are more powerful than the word of the psychotherapist, and the critical indiscrimination which arises through an unordered association of ideas cannot be corrected through a discrimination which is dependent on an orderly association of those same ideas.

Psychotherapy addresses itself to personalities. The personality of the patient represents an entity which cannot be divided into parts. When a patient seeks medical aid he is not able to analyze his disordered sensations to such an extent as to make him willing to have only those symptoms which are of functional origin removed by psychotherapy. What he asks of the psychotherapist is freedom from all his troubles, even those which grow out of organic changes. We have seen that, although psychic treatment cannot directly influence organic disease, a therapeutic effect may be produced by psychic reinforcement of a patient's confidence in

the potency of medicinal or other remedies. In a way, therefore, the patient's hope for relief is not unwarranted, for it cannot be denied that, together with the disappearance of certain symptoms which to a large degree react perniciously on the nervous system, the general condition becomes markedly improved. He who has learned that no better remedy exists for stimulating the digestion, for regulating the movements of the bowels, for inciting the appetite, for influencing the heart's action, than the power of suggestion supported by the authority of the physician, is bound to come to the conclusion this power must be of potent advantage to the entire personality of the patient, and that by means of the combined method of treatment associating the employment of psychotherapy and medicinal or mechanical remedies, the patient will at one and the same time receive both specific and general help.

True, it is not always evident, then, which has been the active factor—suggestion alone, or the enhanced belief in the potency of the other treatment. This, however, cannot be of great significance so long as it is recognized that therapeutic suggestion is of itself capable of prolonging an al-

teration in a person's physical condition. The physician's supreme law must be his patient's weal; how the good is accomplished is of secondary importance and it can be of no consequence whether the patient himself can or cannot distinguish the benefits derived through therapeutic suggestion from those produced by other means. Even should those material remedies which support the action of psychotherapy be inactive of themselves, they are nevertheless worthy of employment because of their opportuneness. It is a foible of human nature which assures the acceptance of concrete things with greater readiness than of mere assertions, and this trait must not be disregarded by the physician in his employment of the combined method of treatment. Even a person of strong character will be more inclined to look forward to the occurrence of certain changes in his condition if the assertion of the physician be reinforced by the simultaneous use of remedies which have a material influence on the patient. The physician cannot dissect the personality of a patient in such a way as to influence the mind to combat functional disorders and symptoms and at the same time to ignore the treatment of organic changes which may exist.

In the one case as well as in the other, whether directly or indirectly, the state of mind of the patient exerts an influence upon the cure. The personality of the patient, in fact, is the most important basis for the individualization of psychotherapy.

The routine practice of medicine is always to be condemned because in various persons special conditions will cause the same disease to take different courses and, therefore, will demand different treatment. But in the exercise of psychotherapy, a consideration of the individual characteristics of a patient is of decisive importance. It should be remembered above all else that personality or character is by no means a fixed entity. People whose characters are unchanging and unalterable under all conditions and in all phases of their development certainly are exceptional. It may safely be maintained that the characters of most persons are subject to many fluctuations as a result of stress and other external conditions, and that pain and suffering seem to alter entirely the personality of an individual.

In his most excellent dissertation on the "Relation of Character Formation to Psychotherapy," Putnam says:

"A person's character is not always just the same—each phase of a multiple personality has its own character, and these phases reappear as *quasi* normal moods. The severe test of illness sometimes develops forms of character that might otherwise have remained undeveloped. Within the orbit of the invalid selfishness sometimes reigns, and narrow egotism, together with sentimentality, ignorance, and weakness of will, and these tendencies may remain active long enough to make themselves felt through modifications of the character. But,—what is more important for our purposes,—unselfishness, devotion, willing sacrifice of ambitions and desires, thoughtfulness, persistent effort, loyalty, the sense of service, may likewise be manifested here in their best form. The invalid may make excursions into certain realms which are rarely open to the well and the strong."

This emotional variation, these fluctuations of character and personality, may be of little significance for medicotherapy or surgical intervention. But, for the psychotherapist, who must exert an influence mainly by words, if not through words alone, due consideration of the mentality, of the psychic constitution of his patient, and of the appro-

priate manner and ways in which his suggestions are to be imparted, are of the greatest importance. No physician of discrimination will speak to a patient who is extremely depressed in the same manner as he would to one who is capricious and obstinate. Such individualization is called for particularly in those patients who at different times manifest the crass contradictions which are concomitant with dissociated consciousness and alternating personality.

The chapter on "Peculiarities of Mental Activity" has shown the differences which exist in the minds of the child and the adult, of man and of woman, etc. If, then, the abrupt fluctuations of character and emotions of each individual are problems which make serious demands on the tact and the wisdom of the psychotherapist, how much greater will these demands be when the problem confronting him is the effective adaptation of his procedure to the understanding of different personalities! His capability for considering individual peculiarities, for weighing conscientiously the methods of action under certain given conditions, and for the adoption of a proper method, will be the surest demonstration of his efficiency. Bernheim's statement that

he never has been able to exert any psychotherapeutic influence on children whose reasoning powers have not yet been developed, must be unqualifiedly endorsed. All suggestion must be adapted to the intellect, to the powers of comprehension of an individual. Hence, suggestion for the very young and for people of but little culture must be conveyed in the most simple words. On the other hand, an intellect which is mature, or a personality of strong and independent judgment, will not be swayed so easily by mere commands, unaccompanied by explanations of the reasons and the expediency of a procedure. Thus ample scope is given to the physician for demonstration of his powers of individualization.

Liébault states that his mere assertion that such would be the case, caused certain peasants who were mentally healthy, but thoroughly unsophisticated, to behold the Virgin Mother. Had he been dealing with more sceptical personalities this surely would have been an impossibility. A patient who, because of his poverty drank only water, received from Liébault the suggestion that for two days at Easter all water would be converted at meals into red wine, and the concentration of expectation

developed by this ignorant person actually caused him to believe this miracle had taken place. Liébault tells of another peasant who often heard it said that any person going into a meadow by a certain specified path would be unable to leave it. The peasant one day went into this field, but no sooner had he done so than he conceived the idea he was using the bewitched path, and so dominated was he by the delusion of his inability to get out of the meadow that he had to be removed by force.

Charcot says he has sent patients suffering from hysterical palsy or contracture, whom he had been unable to relieve through suggestion, to places of pilgrimage, and on their return he was able to verify the fact of their cure.

Effects which can be attained without difficulty in persons of deep religious nature, cannot of course be brought about through similar means in those who are agnostically or atheistically inclined. In order that similar results may be derived from similar causes, as, for example, the removal of hysterical paralysis in different individuals by means of suggestion, the conditions for cure must be the same. In psychotherapy these conditions are not made up, as in medicinal therapy, of chem-

ical affinities, or, as in surgery, of antisepsis and asepsis, but are formed essentially by the personality of the patient and by the sphere of ideas which control him. These facts enable us to deduce the very important principle that the decisive indication for psychotherapeutic influence is given not by the perceptional powers of the physician, but by those of the patient. That physician who would undertake to counteract similar functional disorders in different patients by suggestions of a similar kind, without regard for the thoughts, the character, and the emotions of the patient, would in so doing give the surest proof of his own incapability. He should know that sceptics and persons of critical discernment will be entirely refractory to certain ideas, which would be accepted unquestioningly by children, by the uneducated, and by devout believers.

The treatment of hysterical women is often most difficult. As we have seen, the psychotherapist must combat the disorders of his patients from within the circle of their own ideas. Man, however, is but rarely able to comprehend the mental life of woman, which is so different from his own; when confronted with the labyrinth of female

emotions his wisdom soon fades away. For that reason the psychic treatment of female hysterics often is attended by failure when, *a priori*, success would be expected.

May these few examples suffice to show how important for the success of psychotherapy is the personality of the patient, as well as the ability of the physician to place himself within the circle of the patient's mental life. No suggestion can be effective if it be not adapted to the powers of comprehension of the patient, if it be not linked to the chain of the patient's ideas. Individualization is the shoal on which the art of many an otherwise experienced physician suffers shipwreck.

II. SPECIAL APPLICATION OF PSYCHOTHERAPY

A. The Most Important Methods

THE methods of cure employed by the mystics having been amply characterized as being in part delusive, in part wilful imposture, we are relieved from any further discussion concerning them. Here we will limit ourselves to an explanation of those methods of psychotherapy which have a recognized scientific basis. In so doing a distinction must be made between preventive and curative treatment

1. MENTAL THERAPEUTICS

Psychotherapy makes use of suggestion above all else,—that is to say, it annuls functional disorders and symptoms based on fallacious ideas by arousing opposing ideas, the effectiveness of which is dependent on the individual's inherent disposition for psychic influence. Whether hypnosis should be employed to augment that susceptibility to suggestion can be determined only by the

conditions in each individual instance. Although the opinion that every hypnosis constitutes an artificially produced hysteria is one which we do not share, the fact remains that the hypnotic state certainly is a pathological one. If for no other reason than that, hypnosis, as an aid to suggestion, should be employed only when the inefficacy of all other means has been demonstrated. The number of such instances will be found extremely small by the psychotherapist who is as authoritative and as conversant with his specialty as he should be. In all cases, too, due weight should be given to the fact that the active curative agent is never the hypnosis, but always the suggestion which is implanted during the hypnotic state.

Catharsis, another psychotherapeutic method, differing from suggestion treatment, has gained recognition during the last few years. The aim of treatment by suggestion is essentially an abolition of disordered ideas, the determination of their cause being considered of little importance. The newer method, however, endeavors primarily to trace the disordered ideas to their source by means of psycho-analysis. The question asked in applying suggestion treatment is, "How can the obsess-

ing ideas which weigh upon the mind be annulled?" The first question to be asked under the psycho-analytic method, however, is, "How have these obsessions arisen?"

Aristotle regarded the Greek educational idea of catharsis, that is, the purging of the mind of inharmonious and disordered emotions, as the main end of the fine arts, and in particular assigned to the drama the catharsis of pity and terror as its chief function. The sound basis for this doctrine of thus disburdening the mind is made plain by the common experience of relief obtained by giving vent to excitement, and of distress which is caused by forced repression of harrowing emotions.

The psycho-analytic method assumes the functional disorders of hysterics and neurasthenics or psychasthenics to be attributable in great part to some marked emotional stress, frequently one of early childhood which was repressed at the time it arose and could not be thrown off afterward. The original stress may be forgotten but the morbid feelings and the bodily disorders which they cause continue to persist. Psycho-analysis aims to recall to mind the causative emotional excitation and, by exciting the patient to a confession, to

give him an opportunity to free himself and thus to obtain that relief which we know always accompanies all unhampered expression of thought. The repressed emotions having been discharged, the patient's mind having been unburdened, all symptoms resulting from the repression pass away.

The method of treatment by psycho-analysis received much attention from Sigmund Freud, whose name we have mentioned in the chapter on dreams. Breuer, however, and not Freud, is the originator of this cathartic method, which has met with much just criticism but which contains so much of interest that we cannot refrain from giving more details concerning it.

A female patient in a state of mental aberration was observed by Breuer to be muttering words which apparently were fragments of a subconscious train of thought. This patient was hypnotized, and the words which she had spoken were recited by Breuer. Little by little, through thought association, he was able to revive in her distressing recollections of childhood which seemed to have passed from her waking consciousness. When a number of such recollections had been revived and expressed, she appeared relieved and restored to a

normal mental state; after a time her feeling of relief was supplanted by another aberration, which was removed in the same way. Only after the patient had given vent to all her distressing reminiscences was complete and permanent cure attained. While thus treating this patient, Breuer learned in a disconnected way of severe emotional excitement which had occurred years before and which she had been obliged to repress in consideration of her father's fatal illness. Nearly all the symptoms of her subsequent sickness represented, as it were, a sediment of those distressing experiences, a consequence of the stimulus produced through those emotions, which, having merely been repressed, had lain dormant in her subconsciousness during all that time. The undischarged emotions continued to persist in part as a permanent taint of mental life and a source of apprehensive unrest, and in part had been transformed into expressional movements, which in this case constituted the symptoms of disease. At one time, when a glass of water was offered to her after she had complained of thirst, she gave vent to an expression of repugnance and refused to drink, but she did not volunteer an explanation for her strange behavior. Later, in

hypnosis, she said she once had seen a dog drink from a glass, but through consideration for the animal's owner she was obliged to repress her feeling of disgust. A noteworthy point in the history of this case is the circumstance that a feeling of relief followed the hypnotic disclosures only when they were accompanied by outward evidences of emotion, while the revival in consciousness of a distressing experience, when unaccompanied by such disburdenment, left all the symptoms of disease unaltered; the repressed and pent-up emotions, in fact, remained as a source of suffering until at some opportune moment they found an outlet through an "explosion" of more or less intensity.

This case corroborates the statement previously made that a train of thought brought to light through hypnosis consists essentially of memory images, and not of new ideas suddenly acquired in some mysterious manner. The memory pictures remain in subconscious abeyance simply because the subservient thought associations are not stimulated. As we have seen, one word or another, used at the proper moment, will suffice, by means of stimulation of association fibres, to arouse the latent images to full activity. Complete loss of remembrance

can take place only where association fibres have been disconnected or where the nerve elements in which the memory pictures were stored have been destroyed.

Breuer's method of cure through catharsis, the production of a discharge of the pent-up emotions which were the original cause of the existing trouble, has been not only elaborated, but also, in so far as he rejects the use of hypnosis, modified by Freud. The latter obtains concentration of the patient's thoughts upon his inner life through exclusion of all distracting sensory stimuli. Then, laying his hand on the patient's forehead, he asks him to search for memories apparently lost, and perhaps reaching back into early childhood. He does not regard it as necessary to use hypnosis to eliminate resistance on the part of the patient, but considers it sufficient to assure him positively that he will remember. These memory explorations are aided by Freud through employment of the association law, by mentioning or writing certain words and requesting the patient to mention other words directly related. For instance, the word "ship," through thought association, leads to the words "water," "harbor," "sea-sickness," etc. The re-

sponse is unhesitating and quick where inconsequential matters are concerned. A deliberate, carefully studied answer shows that a sore point, one which the patient tends to cover, has been touched. To overcome such resistance and hesitancy requires much tact and ability on the part of the investigator, and success can be attained only where the full confidence of the patient has been won.

The psychotherapist's task is made still more difficult through Freud's assumption that all symptoms of hysteria have their inception in the sexual sphere—more particularly in unrequited love or in unsatisfied erotic desires. Among the cases described by Freud is the following:

A cultured, elderly unmarried woman presented all symptoms of severe hysteria. Through psychoanalysis there was obtained, little by little, a confession that she had loved a man who subsequently married her sister. At the sister's death, which soon followed, a desire forced itself upon her that her brother-in-law, now free, would marry her. This wish, unworthy of her moral thought and training, was forcibly repressed. The result of this repression was a manifestation of hysterical

symptoms which represented, as it were, a bodily equivalent of the undischarged psychic injury that continued to persist long after the primary emotional excitement had faded away.

In another case, also involving an elderly spinster, the patient accused herself of crimes of all sorts whenever similar happenings were the topics of conversation or newspaper notices. As a result of careful interrogation, Freud ascertained that these obsessions had arisen in consequence of sexual aberrations which followed a disappointment in love. Both those patients recovered through the use of catharsis.

We are quite ready to believe Freud's statement that, owing to the delicate nature of the emotions which originally gave rise to the hysterical symptoms in those cases, a confession could be obtained only with great difficulty, but we are not so willing to adopt his generalization that the more pronounced the primary repugnance to confession may be in consequence of modesty, the greater will be the subsequent disburdenment and the more complete the recovery.

As we have seen, the course pursued in psychoanalytic treatment is quite different from that

followed in suggestion therapeutics. The latter, Freud says, has given him not one permanent success, and he adds that symptoms only have been temporarily obscured thereby. We can easily understand the astonishment of Breuer and Freud following their discovery that symptoms of disease disappear permanently as soon as those painful experiences which have given rise to bodily disorders are recalled to the patient's mind and the patient has been induced to give vent to the emotional processes originally repressed.

Whether suggestion therapy, the aim of which is to combat hysterical and neurasthenic obsessions by arousing healthy antagonistic ideas, has met a rival in this therapeutic method of psycho-analysis must remain a mooted question, in regard to which the unprejudiced critic cannot but have serious and warranted doubts. In our opinion the very basis on which this method is founded, the explanation given by the authors for the origin of hysteria, is unsatisfactory. Every one at some time or other is obliged forcibly to repress certain emotions and to prevent them from becoming manifest. That, in persons of strong will power, accustomed to self-discipline, will cause no ill effect, but where persons

become hysterical as a result of such repression it is a sign that they already have had an unstable nervous system and would have developed hysteria not only in consequence of disappointment in love and unsatisfied erotic wants, but quite as easily from any other emotional disturbance. Therefore, distressing experiences of a sexual character must not be looked on as the sole factor in the production of hysteria, particularly because, as Dercum very correctly maintains, hysteria is encountered in very young children and in very old people, in whom there can be no question of sexual aberrations.

Freud undoubtedly has overestimated the significance of distressing erotic experiences in the production of hysteria. While one person will undergo such experiences and remain healthy, another who does not have them will become a hysteric after fright or any other psychic shock, essentially in consequence of his lowered powers of nerve resistance. Freud was misled into unwarranted generalizations by the accidental discovery through psycho-analysis of the existence of a sexual causative factor in the hysteria of many of his patients. The errors into which he has fallen are

quite manifest, and there can be no doubt that in many of his patients he has, through the questions asked during his memory explorations, suggested matters which previously had been foreign to the patient's mental processes. Thus one woman, having confessed to Freud certain sexual errors of youth, subsequently admitted to Loewenfeld that those excesses never had taken place. There can be no doubt that the mode of applying this method is one which will easily convey suggestions to the patient though they are unintended by the physician. This fact would also explain the uniformity of results which Freud and his school are obtaining.

Emotional shocks sufficiently violent to produce hysteria usually are graven deeply upon the memory, and hardly ever are forgotten to such an extent that they can be resurrected from subconsciousness only by means of an arduous psycho-analytic procedure. With that statement, however, we do not by any means deny the possibility of a disappearance from memory of an emotional occurrence while the secondary bodily disorder caused by it continues to persist. It is also very possible the patient may always retain consciousness of the disturbing experiences through which he has passed,

but carefully conceals them. Such persons merely refrain from acknowledging what they think would lower them in another's estimation. Were this not so, we could not understand why they do not bring about catharsis through confession without the aid of a physician and thus rid themselves of their distress.

A final argument against the practicability of the psycho-analytic method of treatment is the amount of time which its exercise requires. The length of each single sitting necessarily is great, for nothing can be done until the patient has attained proper emotional composure, has overcome any existing depression or confusion, and manifests the necessary interest in the interview; even then he unfolds reminiscences of painful nature only piecemeal, so that, as Freud himself says, three years may pass before a complete recovery is established. That psycho-analysis, under such conditions, should supplant suggestion as a therapeutic method seems hardly credible, and that the newer method will in course of time be modified and made more practicable seems doubtful.

Mention must be made here of the fact that Freud believes dreams to have a certain influence

upon the production of functional nervous disorders. For this reason he endeavors by means of psycho-analysis to recall to memory the dream experience which has been dislodged into co-consciousness and to incite the patient to free expression of words. As Dercum very justly remarks, the same grounds upon which psycho-analysis has been opposed are applicable to dream analysis and to the rôle of a psychotherapeutic factor which is attributed to it by Freud. Although justification is wanting for attributing the causation of functional nervous disorders to dream experiences, unless perhaps it be those dream experiences which are the product of an already diseased nervous system, Freud again falls into an error in considering all dream experience without exception to relate to erotic matters. Certainly this view is often correct, especially in relation to young people, but Freud's generalization assuredly is no more than a gross exaggeration. Furthermore, as we have already seen, the psycho-analytic method also will suggest dream experiences which actually have never taken place and consequently could not have been the cause of the functional nervous disorder that exists.

A third psychotherapeutic method consists in the

proper apportionment of mental rest and exercise. Inasmuch, however, as the word "rest" indicates a cessation of activity, which cannot be attained during the waking state, the word "relaxation" seems better to convey the meaning we have in mind.

Mental relaxation and exercise comprise not only direct suggestive influence, but also those factors which usually are termed educational. The necessity for relaxation and exercise is proved by the fact that the functional capability of every organ suffers through inactivity as much as through overactivity. An organ wastes away when it is not called into action at all, just as surely as it wastes away when excessive demands are made on it. Moreover, this applies quite as much to the brain, the organ of the mind, as it does to the muscles and the other organs of the body.

By relaxation of an organ is meant the relieving of that organ, so far as possible, of the part which it takes in the operations of the general organism, and the facilitation of those activities of which it cannot be relieved. We therefore endeavor to put the entire body in a state which will make as few demands as possible on the affected organ, and that only under conditions as favorable to that organ as

they can be made. By exercise, on the other hand, we understand all those means which will cause an organ to accomplish more than it has previously, the increased activity, however, not being the result of a single output of energy due to strong stimuli, but an evidence of permanently augmented effectiveness. In that permanent effectiveness lies the difference between increased activity due to stimulation and that caused by exercise or training. A sharp dividing line does not exist, since stimulation of an organ naturally will cause an exercise of function. Different individuals react differently to the same kind of stimulation; the stimulus which is physiological for one person may be pathological for another. All exercise produces fatigue and thus necessitates recuperation. When recuperation takes place in a perfect manner, the organ exerted has become slightly more capable than it was at first; but if recuperation has been inadequate, the organ has been weakened, and not strengthened, through the exertion. To find the happy mean, to regulate exercise according to individual requirements, is a task which the physician can accomplish only if he has the proper appreciation of the patient's varying powers of adjustment.

Application of the principles which govern relaxation and exercise of those bodily organs whose healthy functioning produces healthy mental action must be regulated by regard for the intimate connections which exist between brain, spinal cord, and peripheral nerves. Not one of these can be treated individually. Relaxation and exercise of the brain react upon the rest of the nervous system, just as relaxation and exercise of spinal centres and peripheral nerves react upon the brain. This interaction of the various parts of the nervous system takes place, as we have seen in the paragraph on reflex excitability, according to well-defined laws. It is true this has been proved with certainty only in relation to the transmission of sensory stimuli to motor nerves, but enough observations indicating interaction between the central and peripheral parts of the nervous system exist to warrant fully the conclusion that action on one part of the nervous system influences the entire system. The attempt artificially to divide the nervous system into brain, spinal cord, and peripheral nerves for the purpose of treating a single part, the functional disturbance of which for the time being dominates the entire clinical picture of disease without acting

on other parts, is therefore inadmissible, because practically it cannot be a success.

In a book on psychotherapy stress naturally must be laid on psychic treatment, and the supporting curative factors can only be considered incidentally. That restriction should be kept in mind in the reading of the following paragraphs.

As stated, relaxation does not mean rest, for complete rest and inactivity of the nervous system is impossible; a certain activity is a vital condition of the organism. An especially important form of relaxation is sleep. This, as Hoffmann pertinently says, is the form of relaxation which nature itself demands, and by means of which the brain always becomes rejuvenated. Sleep is of more importance than food. We may do without nourishment for weeks, but only a few days of sleeplessness will lead to exhaustion. Numerous experiments, especially those made on young dogs, have proven this to be a fact. Sleeplessness, as is well known, is one of the most common and most distressing symptoms of many diseases. It may be shown by statistics that many suicides and attempted suicides are the result of sleeplessness, together with the exhaustion which accompanies it.

Depth and fastness of sleep may be demonstrated graphically. Following Fechner's proposal to take the intensity of the sensory stimulus required to awaken a person as the gauge of intensity of that person's sleep, Kohlschütter has devised a means through which the sound impressions used for such an awakening are registered in the form of a curve upon a plate. The sound is produced by a pendulum striking with varying force on a plate, causing tones of corresponding intensity. These experiments of Kohlschütter permit us to recognize a typical "neurasthenic curve" which shows that neurasthenics often awaken too early in the morning—in other words, their sleep is interrupted by the slightest sound and they are refreshed for the duties of the coming day only when they obtain a second period of sleep.

A conscientious physician will not combat sleeplessness by the mere administration of narcotics, which always have more or less deleterious associated action, but will endeavor to ascertain the causes of the insomnia and, if possible, to remove them. Those causes, when functional in character, will be found mainly to be hyperæmia of the brain due particularly to active and manifold interests,

disturbing sensory impressions, and a direct obsession, the fear of being unable to sleep. In such cases, too, suggestion, aided perhaps by the exclusion of all sensory stimuli through plugging the ears and covering the eyes, is an excellent means for the relief of sleeplessness and the exhaustion which follows. Frequently that exhaustion alone furnishes the soil for the development of neurasthenic disorders. Besides actual mental disorder, we often find that overstrain, worry, speculation, domestic troubles, etc., cause business men, officials in responsible positions, and physical workers to break down from exhaustion and render them unable longer to fulfil, through exercise of will power, the duties devolving on them.

In such cases mental repose must be brought about not only through sleep at night, but through relaxation of the entire nervous system by day. Even when no symptoms of excitation or paralysis are present, but when character and emotions alone seem altered, a certain laxness and diminished energy exist, weakness of memory manifests itself, the indication or urgent need for relaxation is given, and the necessity for complete change from customary life and activity becomes apparent. Patients

so afflicted must have rest; that is the fundamental requisite for recovery. But they also require diversion, and that can be obtained only in altered surroundings in which nothing will remind them of their troubles and worries. The new impressions which they receive act in the form of suggestion therapy on the disturbing obsessions, which disappear under the influence of brain repose as soon as exhaustion has been overcome and weakness of will has given way to renewed self-confidence.

This brings us to the question of mental exercise as a therapeutic factor. All in all, it may be stated as a rule that treatment should begin in accordance with the principles of relaxation, and subsequently there should be added exercise in accordance with the opinion which observation has justified in regard to the patient's powers of resistance.

As already mentioned, perimetric examination furnishes a reliable gauge for estimating the progress achieved through psychotherapy, for this test of the visual field permits recognition of the existing degree of brain fatigue. Under normal conditions the visual field of a rested brain has a certain defined compass, which becomes restricted in

proportion to the augmenting of fatigue. The rapidity with which such restriction takes place, when compared with the time previously noted as being required to produce the same result under similar conditions and like demands on brain activity, furnishes a measure of the constancy or inconstancy, the increase or decrease of brain fatigue. Certainly this graphic method is more exact than any form of intellectual test.

Mental exercise, not improperly termed brain gymnastics, will be employed in a different manner for therapeutic purposes, of course, from that appropriate to discipline in health. When our object is the restoration of patients to former mental capabilities, enforced activity, which might be borne by a healthy person without detriment, may cause trouble instead of being helpful. Mental training in a sick person is much more troublesome than in a healthy one, and requires a clearer understanding of the functional disturbances which are apt to occur in the course of sensory impressions and memory associations, and in the sphere of the emotions and the will. Then, too, the pedagogue not medically trained often errs in enforcing exercise where repose or relaxation should have been advised.

Good and quick results are sought in order to show startling progress, but the reverse is attained. Exercise and relaxation must go hand in hand with correct judgment. Even the physician can determine only by much practice and long experience when the one and when the other is to be employed, when memory and intellect or when emotions and will are to be influenced the more. That well-planned mental exercise can correct functional disturbances, can retrieve lost powers of action, is shown not only by certain aphasics who, through re-education of the other side of the brain, have again learned to talk, but also by those neurasthenics and hysterics who, through psychotherapy, have gradually subjugated their obsessions and "imaginary," though none the less painful, sufferings through strengthening of their wills.

As we already have intimated, psychotherapeutic success often is not attained, merely because the physician or educator fails to individualize, to adapt his method to the specific case. It is a great mistake, as Heller justly says, to employ a certain method without considering the psychic changes in comportment which take place in the course of the treatment. Far too little attention

may be given to the manifold psychic changes to which the patient is subject and to the fact that the progress obtained by means of relaxation and exercise does not always correspond to that methodical gradation which the physician or educator has planned for. Not infrequently a patient will react to psychic impressions in a manner different from what analogy to a former similar experience would lead one to expect. Then it is that the physician or educator can demonstrate his capabilities by modifying his method according to the varying reaction powers of one and the same or of different individuals, without ever losing sight of the object of his work. He who lacks the requisite persistency to await the effect of methodical mental relaxation and exercise is likely to become disheartened by the absence of expected results, to have recourse to newer and newer methods, and then to achieve nothing more than the production of disturbing complications which lead far from the desired purpose.

These considerations admit of but one deduction —that institutions conducted and supervised by physicians of specialized training constitute the proper place for the application of such methodical

relaxation and exercise of the brain and the nervous system. Patients in such institutions are freed from all injurious influences such as errors in training, noxious suggestions, inappropriate literature, and other things which permit nervous disorders to thrive. Furthermore, such sanatoriums, a number of which have been in existence for many years, particularly those in Germany, are equipped with all psychotherapeutic appurtenances and accessories, not the least of these being an equipment for treatment by means of exercise and occupation.

By means of work adapted to the capabilities and tendencies of the individuals and allotted in accordance with the principles of relaxation and exercise, their attention is distracted from their nervous disorders; encouraged by successful labor, the patients regain self-confidence and again find pleasure in life. That alone means that much has been accomplished, but, in addition, altruistic feelings are aroused through the work which the patients voluntarily furnish in agriculture, horticulture, or craftsmanship, and which they know contributes to defraying the necessarily high cost of the institution and thus accrues to the benefit of other sufferers.

No matter how excellent the organization of such a sanatorium, no matter how great its reputation, its one aim must be to lead the patient, by means of relaxation and exercise, not only to his former condition of health, but also to a recognition of the manner in which he may successfully combat in the future the damage which is the necessary accompaniment of all industrial competition.

2. PSYCHO-PROPHYLACTIC TREATMENT

The subject-matter of the preceding chapter in part covers the ground of psycho-prophylaxis. Mental relaxation and exercise not only serve as co-operative factors in the re-establishment of functional activity of the brain and the rest of the nervous system, but also act as a remedy through which persons suffering from congenital or acquired nerve weakness become better qualified to resist threatened psychic dangers. Thus psychotherapy follows the principle which governs all other branches of therapeutics, that prevention of disease is better than cure.

The task of psycho-prophylactic treatment is essentially educational, its object being not so much the cultivation of the intellect as the forma-

tion of character and will power. Through education, says Hoffmann, is furnished the basis for enhancement of the productive capability of our most important organ, the brain.

We have learned that a person feels what he conceives if he is once convinced of the truth of his conception. Under those conditions he may feel that he is sick and pass through all the qualms of suffering, even when all organs are healthy and when he has not been exposed to an external injury or disease-producing agency. The sufferings of the neurasthenic or the hysteric represent bitter actualities even when the ideas on which they depend have no foundation in fact—that is, are purely imaginary. Hence it must be apparent that education may produce, as well as it may remove, predisposition to disease, and that the natural sciences are correct when they require education to be governed, not according to transmitted patterns, but in accordance with our comprehension of the nature of brain and nerve activity.

This is not the place for a consideration of the reasons for the persistent increase of neurasthenia. Perhaps many individuals do break down prematurely, not in consequence of any hereditary taint or

life amid specially unfavorable hygienic surroundings, but because they have been forced to exert themselves beyond the measure of human capability. Perhaps, too, such breakdown is the result of that constantly augmenting craving for self-gratification and pleasure which has permeated all social classes and which, through over-satiation, leads to a search for ever more and more pernicious means of stimulation. While both those factors may be recognized as operative causes, the explanation, in my opinion is to be sought in the inability of the average brain to adapt itself with sufficient quickness to the gigantic progress and the rapid changes which conditions of life now are undergoing. This seems to me at any rate to be the most plausible explanation for the increase of neurasthenia among those people who are dependent on their own labor for their means of subsistence. As a matter of fact, the number of weaklings is increasing; one-sided cultivation of the intellect is permitting the emotions to wither; the ethical side of character and formation of will power is becoming more and more neglected, and mastery of the lower passions is less common than ever before. Education's first duty is to counteract such palpable

evidences of degeneration. The annals of the history of civilization teach us in unmistakable terms that races as well as individuals irreparably decline when the germs of degeneration, strengthened by hereditary influences, are permitted without hindrance to proliferate.

Psycho-prophylaxis can do even more toward better fitting adolescent youth for its struggle for existence in making the interactive relations between body and mind,—more especially the reaction which the psychic state exerts on the course of bodily processes,—serve for methodical discipline of thought and imagination, emotion and will. If by that means nothing else is achieved than safeguarding the young from those dangers to which they are exposed through sexual aberrations and alcoholic excesses, much will have been accomplished.

But if, in addition, love for work and aversion to idleness can be stimulated, the fountain-head of neurasthenic and other nervous states will be blocked. The sole difficulty consists in so selecting and apportioning activity that it will become a pleasure and concord with the desires and capabilities of the individual. Wherever that purpose

is not accomplished, work becomes a source of emotional depression and nervous disorder. Much criticism has been made of strain in school as a cause of neurasthenia among children. In general it is my opinion that the exactions of an education which keeps pace with the progress of the times must grow. Although I freely admit that, through too much learning by rote, the memory is excessively burdened, I do not consider the demands made by the school excessive for a normal brain. That, however, does not apply to children who are mentally deficient, who, without exactly being abnormal, still have brains of lesser capabilities and therefore are overtaxed by the demands made on them. For them psycho-prophylaxis must endorse the establishment of special schools, a provision which is steadily growing. The instruction given in schools organized for children of average capabilities must become a source of neurasthenia for those who are mentally deficient. Moreover, the emotional depression caused by inability to compete with their comrades, together with the ridicule they are obliged to endure as a result, may and often has become a psychic detriment of grave nature. Wherever such mental deficiency is not de-

pendent on bodily abnormalities, eye-strain, adenoids or other causes easily removable, stress must be laid, in its psycho-prophylactic treatment, on relaxation and not on activity.

To impress the youthful brain with noble and beautiful thoughts is but one function of educational training. It is quite as important to regulate by means of habit the flow of ideas, the impulses of the will, and their dependent actions, so that, as an integral possession, they will fortify the personality for its battle of life. It is true the ideal, a healthy mind in a healthy body, can but rarely be fully realized, but it is better to have a healthy and efficient brain in a crippled body than a crippled mind in a normal body.

Child-training, however, is not the sole task of psycho-prophylactic treatment. Adults, too, require training—frequently more so than children. Consider, for example, those drones of wealth whose entire lives are filled with outward form and trivialities, whose lack of serious purpose makes them easy victims to the unbridled play of their imaginations. Constituting, as they do, so large a proportion of sufferers from neurasthenia and other psycho-neuroses, they teach us particularly that in-

ordinate relaxation leads to imaginary disorder, ideational diseases, quite as much as does over-taxation through work.

Let us here emphasize the principle that health cannot, as Hoffmann expresses it, be absorbed in comfortable repose with the aid of a drug, but must be acquired and maintained through useful work. When races or individuals, enervated through luxurious living, unwilling to accept further cares or obligations, tend toward "race-suicide" through their need for repose, and, worshipping a morbid feminism, look on hard work as a disgrace, they represent the dead twigs of humanity, which have fallen and must be replaced by fresh shoots; they have become useless and must give place to those who, through earnest work, have remained young, strong, and active.

May these few allusions suffice to indicate the unlimited field open to psycho-prophylaxis. These times of relentless, brutal competition in all fields of culture require, above all, combative characters, men of action with wills of force and purpose. Psychotherapy will have an important influence in the production of such characters, in counteracting excessive effeminateness and sensitiveness, since

the positive ideas which it arouses exert not only a curative, but also an inherent preventive action. Imagination kept within proper bounds by trained habit enables us to protect ourselves more or less against detrimental influences; it not only guards us from that fear which increases actual suffering or even produces disease, but it also augments our capacity for the enjoyment of all that is good and beautiful. This occurs in conformity with natural laws. Observation of them keeps us strong bodily and mentally; neglect of them inevitably leads to degeneration of the race. This degeneration, manifesting itself in an alarming increase in nervous troubles, as well as in other ways, can be combated only by training the brain to adapt itself to the conditions of life furnished by the intensity of work and progressive culture.

Cui bono? Why put ourselves to all this trouble? Who can be helped by such means? If such questions can still be asked, the nature of psychotherapy has not been grasped. Psychotherapy must stand or fall together with the right of existence of the entire science of medicine.

B. Practical Examples

Before illustrating the action and uses of psychotherapy by means of practical examples, it will be well once more briefly to remind the reader that suggestion acts directly as well as indirectly, and that he must keep in mind the distinction between the influence exerted by suggestion when employed alone and the influence it exerts as part of some other therapeutic procedure. In practice direct suggestion and the exclusive employment of psychotherapy are usually associated, while indirect suggestion is linked with other therapeutic measures.

Naturally psychotherapy primarily shows its effectiveness in that class of pure neuroses or psychoneuroses which are dependent exclusively on ideas and imagination. That class is made up in great part of neurasthenia (psychasthenia) in its varied forms, sexual neuroses, fright neuroses, and hysteria, with its manifold ramifications. To those must be added numerous nervous symptoms which also may be psychically induced, such as sleeplessness, loss of appetite, habitual headaches, nervous dyspepsia, imperative thoughts and acts (obsessions), hypochondriacal depression, and muscular spasms

of an epileptoid or choreoid character. In all such conditions the assurance that the affection will pass away, given by the physician and willingly accepted by the patient, usually suffices to effect a cure. But such exclusive employment of psychotherapy cannot be successful against those affections which are a combination of organic disease and functional symptoms enhanced by the fantasy and the imagination. True, the psychic symptoms of disease in such composite affections may be cured, or at least ameliorated by direct and exclusive psychic influence, but the symptoms dependent on organic disease can be influenced only indirectly by psychic means, the extent of such influence being dependent on the degree to which the force of ideas may apparently mitigate an existing malady and at the same time augment one's confidence in the beneficial action of any other therapeutic measure which is being concomitantly employed.

A just estimate of the following illustrative cases can be obtained only if these differences in the various modes of psychotherapeutic procedure be kept in mind. Moreover, let us not fail to consider that in psychotherapy, as, in fact, in therapeutics in general, the removal of the cause of a

disorder by the employment of any specific treatment is an ideal which is but rarely attained. All specific treatment premises knowledge not only of the causes of the disease against which it is directed, but also of all the changes which such disease has produced in the nerve cells; and, needless to say, this knowledge still is very incomplete. The art of medicine, however, cannot sit helplessly by awaiting the time when the science of medicine will have given us complete cognition of the processes which take place during the causation and the subversion of disease. The physician must act; hence he is obliged in most diseases to confine himself to symptomatic treatment. The task of symptomatic treatment is to eliminate from the numerous conditions which in the individual case determine the course of a disease those symptoms which stand in the foreground of the picture. While the fulfilment of this task does not strike at the root of the trouble, it does attain distinct successes through the palliation and repose which it brings about. This is particularly true in psychotherapy, which intrinsically can treat only symptoms. Phobias and obsessions of neurasthenia or the emotional outbreaks of hysteria, with their

physical associates, may be removed, and relief may be brought about which will react favorably upon the disease itself, but no one can maintain that the neurasthenia or the hysteria has thereby been cured. Still, the treatment of symptoms requires constant attention to the entire disease as well as to the entire personality of the patient. Each symptom to be treated must be recognized as merely a part in the object of attack.

Take the case, for instance, of a patient who is unable to obtain rest by night or day on account of persistent pain. He does not sleep, takes no food, and, as a result of malnutrition, is in danger of dying through exhaustion. Morphine or some other pain-relieving remedy is then prescribed by a physician. Although, of course, the cause of the disease is not removed thereby, sleep is restored with the cessation of pain, the appetite returns and tissue waste is prevented. All of which represents a therapeutic gain. Or, let us take the case of another patient suffering from urinary retention in consequence of local obstruction. The physician causes the bladder to be evacuated regularly by means of catheterization. Thus, again, only a symptom and not the cause of the disease is re-

moved, and yet it is certain this symptomatic treatment means much to the patient and favorably influences the course of the disease which afflicts him. When all has been said, every disease, clinically considered, is but an agglomeration of symptoms. Therefore, if in any disease we have no therapy which will remove the cause of the disease, but are able to cause its symptoms to pass away one by one, we certainly have brought about one of the objects of all treatment, namely the subjective feeling of well-being of the patient. Then, too, psychotherapy often must seek its end by this same indirect means of symptomatic treatment. If the neurosis itself cannot be made to disappear, then the removal of obsessions and other disturbing symptoms will constitute the task allotted to psychotherapy.

Understanding this, we may classify functional diseases, as Déjérine and Gauckler have done, according to the dominating symptoms; *i. e.*, into affections of the digestive, urinary, sexual, respiratory, circulatory and sensory organs, affections of the nerves and muscles, and psycho-neuroses in a more restricted sense. With no intention of cover-

ing this entire field or of taking up these varied symptoms seriatim, let us begin with those functional disorders which manifest themselves in digestive disturbance.

A drastic example of this nature is furnished by the case of a man of middle age, with no hereditary taint and who never had been sick, who arranged for a trip to Europe to obtain a much-needed vacation, and who about a week before the time set for sailing, was taken with nausea and vomiting. His malady increased from day to day and could not be controlled by treatment. The most careful physical examination failed to reveal any cause for the trouble. Finally, when no food of any kind could be retained, the trip had to be given up as the patient was too ill to leave home. The distressing state persisted until the steamer had left without him, and then all symptoms of illness disappeared at once. The abrupt change, together with other facts, led me to believe the patient was suffering from a species of psychic seasickness. Feeling well, the patient scoffed at that idea of the mental origin of his trouble. The episode had been forgotten, when, six years later, a trip abroad again

was planned and cabins secured. A week before the time set for that sailing, the same symptoms of nausea and vomiting recurred. This time the tickets were given up after two days of illness, and again with the same result, cessation of the symptoms. Since that time, as a result of many interviews and much explanation through which the patient was made to realize the cause and to understand the development of his attacks, he has been abroad without more than the actual mal de mer which a stormy voyage entitled him to have.

I could report another such case, which, however, did not have the same successful issue because the patient would not persist in the endeavor to overcome his trouble. He was not obliged to go abroad; the trip was merely for pleasure, so battling was not worth while to him. Similar examples could be quoted endlessly from the experience of every busy physician and they are being given now not as curiosities, but as samples of ordinary occurrences.

A frequent symptom of functional nerve disorder is anorexia, loss of appetite, or aversion to certain or all kinds of food. Notwithstanding the organs of digestion are apparently in the best of condition

and chemical examination of the stomach contents reveals no disorder, patients believe themselves to be suffering from serious gastric disease, apprehensively abstain from all food which they consider indigestible, show a repugnance to a food or a beverage which at one time or another has, in their opinion, caused distress, and thus, through their constant fear of possible ill effects from food, lead lives of anxiety and self-observation. Physicians constantly are hearing patients say they cannot take this or that food, that it is poison to them; that they cannot take one medicine or another, or can take it only in a certain form, as in a capsule, but not in powder or solution. Occasionally these complaints are due to an actual idiosyncrasy of constitution, but in the majority of instances they are pure products of the imagination. How easily such an idea may take root and thrive, if not recognized and combated, is demonstrated by the following case.

A physician of broad general culture and large professional experience, accustomed to taking claret with his dinner, was dining at a hotel, and, immediately after drinking a glassful of that wine, was taken with nausea and vomiting. He ascribed

his illness to the claret, which to him seemed adulterated. At dinner the following day the first mouthful of claret, which came from another source than that of the preceding day, caused nausea, and from then on the doctor no longer was able even to taste red wine without the recurrence of nausea. Other wines did not affect him in the same manner. He abstained from claret for several years and then, realizing the cause of his inability to drink it to be purely psychic, the doctor rebelled at his weakness and, by energetic counteraction, succeeded in permanently overcoming it.

The development and growth of such an erroneous idea in a person of neurotic constitution is well illustrated in the case of a girl twenty-three years of age whose trouble originated in an endeavor to reduce her weight. Thinking she was too stout she began dietary restriction by dispensing with potatoes and bread. Not losing weight rapidly enough to suit her, she discontinued eating starchy food of any kind and sweets. Finally, when she had lost about twenty pounds, she was apparently satisfied and made up her mind to return to a normal diet. For some reason or other the starchy foods now disagreed with her; after partaking of

them she suffered much from flatulence and belching. She sought relief by eliminating one thing after another from her diet, and soon began to run down owing to insufficient nourishment. When her attention was called to her anæmic appearance she answered, "I never felt better in my life." Little by little more and more food was cut out, until she was taking but a bowl of soup, a cup of milk, and one egg in twenty-four hours. Following an appeal for her to eat, she consented, took a full meal and promptly vomited; and that was the first of a series of vomiting spells. Her reasoning then was, "Why eat at all, since everything I take is vomited?" When I saw her, she was thin, pale, exhausted, and almost bloodless, with a weak and rapid pulse. She appeared like a person dying from starvation. Separation from her family, isolation and psychotherapy in the form of re-education gradually led to her recovery.

Such cases are not unusual. Not infrequently a severe anorexia of purely psychic origin, when not opportunely treated, has led to death. On the other hand, the most marvellous results obtained in this and analogous states by psychic treatment form part of the experience of every neurologist.

The suggestions of cure are so promptly accepted that patients who hitherto have refused food of any kind, and who, on account of their state of inanition, have to be fed with a stomach tube, experience a return of appetite after brief psychic treatment and take food with avidity.

A case reported by Dubois is that of a man fifty-eight years of age, suffering from chronic diarrhœa, which had been treated by a specialist according to all rules of science, but without success. Dubois again tried the various remedies and dietetic prescriptions given by the physician who had preceded him, but without avail. A full general diet, through which he had attained good results in similar cases, also failed; in fact, the diarrhœa increased from day to day. Discouraged by his failure, the Bernese professor did not know "to which saint to appeal." In the beginning of the treatment Dubois had sought in vain for nervous symptoms, but these gradually made their appearance until he became convinced that, as a result of hypochondriacal depression, the patient was constantly thinking of his condition, and in this manner himself was the cause of the long duration of his trouble. The patient then also ad-

mitted he talked frequently to members of his family about his diarrhœa and always prophesied its recurrence before sitting down to a meal. The patient gained control of himself and his ailment disappeared after Dubois had explained to him that, notwithstanding the absence of any discoverable inflammation, the bowel trouble had increased, that this was due essentially to constant apprehensive expectation, and that the patient had done wrong in annoying and unnecessarily tyrannizing himself and the people about him by his hypochondriacal ideas.

This case, it might be said, well exemplifies Dubois's statement that "the nervous patient is on the path to recovery as soon as he has the conviction that he is going to be cured; he is cured on the day when he believes himself to be cured." We, however, believe this criterion, the self-feeling of a patient after the application of a remedy, to be one of but little logical force. It would be better to say the patient is cured when the conditions which have caused his sickness, and which tend to maintain it, have been removed.

A case that may be compared with Dubois's is one recounted by Hirsch. To a young girl suffer-

ing from torpor of the bowels Hirsch suggested during hypnosis that a daily movement should take place at three o'clock in the afternoon. The result was the desired one. The patient then arranged to go on a journey, and, in order that she might not be inconvenienced at that inopportune time of the day, Hirsch suggested in another hypnosis that no movement would take place on the day of her trip until eight o'clock in the evening, after she arrived at her destination. After awaking from the hypnosis the girl retained no recollection of the suggestion which had been made. Its efficiency may be seen, however, from a letter which she wrote to a friend, saying: "Please tell the Doctor his suggestion did not act punctually this time, for yesterday, for the first time, my bowels did not move at three in the afternoon, but at eight in the evening."

Breuer recounts the case of a man who witnessed an operation performed on his brother. It was a matter of forcible extension of a stiff knee. Who felt the pain? Not the deeply narcotized patient, but the brother who was looking on, and he suffered for an entire year from this pain caused entirely by his imagination.

An analogous case, reported by Moll, is that of

an opera-singer without organic heart or lung disease who maintained that whenever she was in a closed room she suffered from shortness of breath and an attack of suffocation, which disappeared at once when a window was opened and fresh air came into the room. Medical treatment had failed to relieve her of this evidently functional trouble. One evening after a performance she came home ill and went to bed at once. After a few hours she awoke with all manifestations of severe respiratory oppression. The only means of relief, she thought, would be the opening of a window, but she felt too weak to get up. In her fear the oppression would increase, she took up a candle-stick standing near her bedside and threw it, as she believed, at the window. The noise of broken glass falling to the floor indicated the accomplishment of her purpose. At once she felt very much relieved by the "inflow" of fresh air and quickly went to sleep. The next morning, awaking well and refreshed, she saw to her great surprise that it was not the window which had been broken, but a looking-glass hanging beside it; that, therefore, there had been no inrush of fresh air, and that the relief from her oppression, as well as its origin, had been due entirely to her

imagination. From that time she really was cured and the attacks of oppression no longer recurred.

Let us also briefly consider here those neuroses which so often follow injuries in accidents, and which are of especial interest from a medico-legal aspect on account of the prolonged earning incapacity which they often entail. In any railroad accident, during routine factory work, injuries may be suffered which permanently restrict or, perhaps, entirely destroy a person's capability for self-support. Many similar cases are encountered, however, in which no organic disorder is discoverable or in which the organic disturbance primarily present passes away, but certain disorders of function, essentially dependent on auto-suggestion due to fright and dread, remain. Very often the sufferers from traumatic neuroses—those due to accidents—are persons of neuropathic constitution, though even persons previously healthy are not immune from such nervous manifestations. Those manifestations arise days, weeks, or months after the accident, often after symptoms of concussion of the brain and the spinal cord have been present and passed away, often without being preceded by any disorder immediately due to the ac-

cident. The chief functional manifestations of the later peroid are hypochondriacal or melancholic depression, tearfulness, feelings of head pressure, tremor, increased excitability of the sensory nerves, motor insufficiency, disorders of the heart and respiratory action, with which also may be combined symptoms due to organic changes consisting chiefly in affection of the smaller blood-vessels of the brain and the spinal cord.

The fact that these varied evidences of disease are due to one and the same cause, accident, justifies their combination into one group, even if the view that traumatic functional nervous disorders represent a certain well-defined picture of disease be not generally endorsed. Some writers lean toward the view that the neurosis which occurs after a traumatism must be classed, according to its predominating symptoms, as a hysteria, a neurasthenia, or a hypochondriasis. While a definite analysis is by no means always possible, it is certain that the most important factor in the production of all traumatic neuroses is not the physical injury but the psychic shock which accompanies it. Therefore, in conformity with the psychic causation, the treatment must also be a psychic one.

What materially adds to the difficulty of treatment of these neuroses due to accident is the litigation which usually follows a claim for damages made by the victim and the fear that the award for damages may be lessened through a rapid recovery. This by no means signifies there is any conscious simulation. Little knowledge of human nature is necessary to understand that the promise of permanent support or a lump sum paid in compensation for injuries will exert a truly magical curative influence on certain people, while the mere assurance that they are cured and perfectly able to work, when unaccompanied by material compensation, will prove of little avail. Notwithstanding the difficulties with which treatment of these cases is beset, good results are frequently obtained, especially in those cases in which there is no question of claims for damages, through psychotherapy alone, with or without hypnosis.

The following case reported by Dubois shows how the circle made up of suggestion, fear, emotions of other kind, and bodily disorder is formed.

An intelligent literary man, twenty-four years of age, accidentally struck his knee against the edge of a table. He said the blow was insignificant and

caused hardly any pain. He always had a notion, however, that injuries to the knee were particularly dangerous. Under the influence of fear, which, as we all know, augments our sufferings, the disorder grew and the apprehensive patient consulted a surgeon, who found nothing wrong, but advised rest in a reclining-chair and cold applications. Under those conditions the idea of illness gained more and more ascendency over the patient's mind. One day, as a result of self-observation, he felt something was wrong with the other knee. He communicated his fear to a physician, who considered the involvement of the other knee quite possible because, he said, there existed a "symmetry of sensibility" between both legs. A few days later the patient bumped his right elbow and, in conformity with this law of "symmetry," which he now understood, he soon had pain in the left elbow, too. In consequence of inactivity his digestion became sluggish, his appetite waned, and he believed himself to be suffering from cancer of the stomach, the symptoms of which he then studied with the aid of popular writings. For months he lived on a restricted diet, lost in weight, and became more and more ill. The emotional state induced

by his notion of having cancer in turn set up numerous disturbances of function, such as palpitation of the heart and shortness of breath, which still more increased his fears. Thus he got into a vicious circle in which his emotional processes produced bodily disorders and those reciprocally aroused new emotions. In this deplorable state the patient, who in the beginning actually was not sick at all, the entire fabric of his disease having been woven essentially by his imagination and the resultant incorrect mode of life, existed for eight years. Then he went to Dubois, who cured him in a week through psychotherapeutic influence.

The following case, which I observed myself, also shows the influence of suggestion in a neuropathic individual after an accident. The patient, a girl of twenty-two, was thrown from a bicycle and fell on her left side, striking on her shoulder and the the left side of her head. Dazed, but not unconscious, she arose and, thinking she had dislocated her arm, walked to the office of a near-by physician. He, believing her to have been seriously injured, sent her to a hospital, where she was placed in a surgical ward. Careful examination in the hospital failed to reveal any symptoms of

organic trouble, but she was allowed to remain so she could recuperate from the emotional shock caused by the accident. On the fifth day of her stay, a woman suffering from a brain injury was placed in the adjoining bed. During the night this woman had a convulsion beginning in the left arm, and that formed the topic of a conversation on the following day between one of the internes and a nurse. Our patient, the girl, heard this conversation, and the same evening began complaining of renewed pains in her left arm. These pains grew in intensity, the arm began to shake, and in an hour she had a generalized convulsion. On several subsequent days she had similar convulsions, which bore all the characteristics of major hysteria. Examination showed a loss of sensation of the skin and of the mucous membrane of the entire left side. The girl was removed from the ward, isolated, and treated as a case of hysteria, special pains being taken to explain to her the psychic genesis of her trouble. In a fortnight she was discharged as cured.

Neurasthenoid cases cured by psychotherapy could be cited in large number. Typical of this class is the case of a man with all symptoms of

marked nervous exhaustion, fear and restlessness, weakness and tremor of arms and legs, incapacity for work, sensations of dizziness, sleeplessness, and loss of appetite. A death in his family brought on a depression which caused him to wish for nothing but death. No symptoms of organic disease were present. This patient was cured through suggestion, one symptom after another being explained to him to show him its origin, its development, and its influence in the production of other symptoms. First his sleep returned, then his appetite became better, next his general nutrition improved, and with that all his nervous troubles disappeared.

Medical literature is replete with cases of various forms of sexual neurasthenia, masturbation, sexual impotence due to fear and apprehension, and perversions in the same domain, all of which have been cured or, at any rate, materially relieved by psychic treatment. The same holds true of the various obsessions and phobias which so often thrive upon a neurasthenic or hysteric soil, the most common of these being agoraphobia, the fear of open spaces, claustrophobia, the fear of being alone in a confined space, stage fright, and the fear of a fear. Cases also could be quoted showing that the

remarkable influence exerted by psychotherapy is not confined to pure neuroses and psychoneuroses, but extends also to diseases which are only partly dependent on psychic causes, such as stuttering, nocturnal bed-wetting of children, neuralgias of various kinds, chronic alcoholism, and morphinism. Even pronounced anæmias may be beneficially influenced through suggestion therapy in so far as an improvement of appetite, digestion, and general condition by psychic means gives an impetus to the formation of hæmoglobin and an increase in the number of red blood-cells.

Finally, in so far as purely organic diseases are concerned, psychotherapy can serve only to palliate some of the distressing symptoms, while, of course, it can have no influence on the organic changes themselves and the process of disease will take its own course, whether toward recovery or toward death. But even when the changes which disease has produced in the body can no longer be remedied, and when the patient, in spite of surgery, medicine, and all solicitous care, is doomed to languishing dissolution, the power of the mind to master disordered feelings through exertion of the will causes pains and distress to appear less intense and

makes disease more endurable. Through fostering and strengthening that power in his patients who are hopelessly sick, the physician can best demonstrate his powers for good. As Billroth said in a speech delivered in 1891, "The patient comes to the physician for advice, consolation, and hope; if you give him nothing of this, you may be an excellent diagnostician and prognosticator, but you are no doctor."

CONCLUSION

THE road we have travelled has been long and arduous, and we have now come to the end of our excursion into the fields of suggestion and psychotherapy. Like the wanderer who has reached his destination and looks backward to recall to mind the chief stages of his journey, let us summarize and take a brief retrospect of the chief results obtained through our medico-psychologic study.

Above all we have learned that, without a knowledge of the facts which govern suggestion, no comprehension of psychotherapy can be had. The doctrine of suggestion, in turn, premises a knowledge of physiologic psychology based on observation and experiment. Just as the entire art of medicine was dependent on accident and chance, so long as the cause and the nature of disease were unknown, so psychotherapy, without the groundwork mentioned, would be pure speculation, a groping in the dark. Medicine during the last century has been placed on an entirely new basis, through which alone it has become possible for

psychotherapy to develop from a mystic hocus-pocus into an exact science. As chemistry has arisen from irrational alchemy, as astronomy has developed from that pseudo-science, astrology, so has modern psychotherapy grown from mediæval belief in miracles, from the cloudy conceptions of animal magnetism and from the spiritistic trickeries of a Cagliostro and a Slade.

This transformation cannot be better pictured than by citing the words of Mephistopheles to the student in Goethe's "Faust":

> "To grasp the spirit of medicine is easy;
> Learn of the great and little world your fill
> To let it go at last, so please ye,
> Just as God will." —*Taylor's Translation.*

Then it was not known that diseases were processes of nature governed in cause and course by inalterable laws. Then disease was attributed to astral influence or to some other incomprehensible power. Then the pious believed, as some of them do to-day, that diseases are visitations of God, punishment for sin, and that recovery can be obtained only through God's pardon, all going at last "just as God wills."

To-day we need no longer fold our hands in

resignation and inactivity. To-day we know that there is no intervention of supernatural power in the laws of nature, and whether diseases will become our undoing or whether we will be able to deflect their course or to cure them depends essentially upon our comprehension of the physical and chemical forces which nature holds in store. The ills which oppress us are the result of our own ignorance or folly—hence can be combated only by appreciation of their productive causes and by systematic modification of the natural laws which govern them. This applies with equal force to those functional diseases for which psychotherapy is to be the means of cure.

We hope we have succeeded in showing to what extent a physician, by means of suggestion, can influence the brain activity and the imaginative power of his patients in order to relieve them of suffering. Is not the influence exerted by methodic commendatory advertisements a matter of daily experience? Do not the newspapers, through dissemination of questionable, or even entirely untrue statements, create and foster belief, sacrifice, and enthusiasm, as well as the lowest passions? Why should not the physician make use of this power of imagina-

tion in order to restore his patients to health and contentment? The determining and difficult measure for this purpose is the employment of therapeutic suggestion in accordance with a well-defined method, a method based on the scientifically proven fact that an effect which the human organism anticipates tends to take place. There is nothing wonderful in this. There is no need for looking far afield, no need for seeking supernatural causes. The natural explanation lies close at hand. It is contained in the previously noted law of ideational dynamics, according to which, if the suggestive receptivity of an individual be sufficiently pronounced, suggested concepts will elicit sensations and movements which heretofore have been missing, and, on the other hand, will do away with sensations and movements which previously were present. All personal influence which a physician exerts, consciously or unconsciously, is more or less dependent on this method. The confidence produced by his comportment, the assurance of his demeanor, his solicitude for the patient's welfare, his example, his verbal or written dictates, all act suggestively, even when the suggestion is not intended by him or recognized as such by the patient.

If, then, unintentional suggestion emanating from a physician can prove of service as a mere aid to medicinal or other curative factors, how much more potent must be the action of suggestion when it is employed purposely by a psychotherapist trained as a specialist?

We have seen that scientific psychotherapy is based, on the one hand, on the laws of psychology, and, on the other, on the pathogeny of neuroses. What we call "mind" is nothing else than a vital manifestation of the brain in accord with well-defined laws.

To recapitulate briefly, the processes which take place to produce such manifestation are: All our concepts arise from sensory perceptions which impress themselves upon our consciousness in a manner not yet completely understood. These sensory perceptions become stored up as memory images, which may be reawakened later, in certain brain cells connected with one another through association fibres. One person may have a good memory, another a bad one, and that signifies the brain cells of the one retain impressions received longer and more firmly than do those of the other. By means of association, sensory perceptions and

memory images become joined into ideas, which are the more complex the greater the number of sensory impressions which the adolescent being takes up. In conformity with the law of psychophysical parallelism, ideas are accompanied by physical expressions, such as muscular movements, increase or decrease in the regularity of heart action and of respiration. What cannot be emphasized too strongly is that this reaction of ideas upon bodily functions constitutes the natural basis of suggestion and psychotherapy. Functional diseases also, are manifestations of life under abnormal conditions, but those abnormal conditions consist in false ideas and not in organic changes. The same idea which will so alter the quality of a sensory perception that it will make a person drink water, thinking it is wine, or eat a potato with special relish under the impression that it is an orange, will also cause an inhibition of function or produce other physical disturbances. Functional disorder will give way to a normal state as soon as the condition under which it exists has again become normal—that is, when the false ideas have been removed by suggestion. Furthermore, we have seen that psychotherapy has at its command not

only treatment by suggestion, but also the psychoanalytic method of Freud. True, this method still requires corroboration, so a final judgment cannot yet be pronounced on it. Perhaps, after all, catharsis, that postponed discharge of the emotions which primarily have produced the hysterical symptoms and neurasthenic obsessions, may have a certain measure of success alongside or apart from suggestion. Before closing, we would direct attention once more to the fact that the capable psychotherapist need not, as a rule, employ hypnosis to effect an increase of suggestibility. On the other hand, neither in prophylaxis nor therapeutics can he dispense with those important aids, mental relaxation and exercise, appropriate occupation and training founded on psycho-physiologic principles, which will tend to fortify the power of nerve resistance.

The knowledge which has been gained of the nature of suggestion and psychotherapy certainly represents progress of no ordinary kind, for not only has it materially widened our comprehension of the human mind, but it also has taught us that the therapeutic application of all psychic methods should and must remain in the hands of the trained

physician. Even if such treatment be limited to the cure of diseases of the "imagination," functional disorders, and symptoms wanting in discoverable organic change, still it can never be acquired through a study of books alone. No one can become a capable psychotherapist except through natural aptitude and tact, medical training, and experience.

SUGGESTIVE THERAPEUTICS

APPLIED HYPNOTISM

PSYCHIC SCIENCE

To the Memory of My Mother

whose beautiful example and most frequent suggestion, "Be sure you are right and then go ahead," has given to my life whatever dynamic quality characterizes this book.

PREFACE.

I bring to the consideration of the medical profession not merely the facts of personal experience and clinical evidence as proof of the value of suggestive therapeutics in the general practice of medicine, but also a **detailed explanation of how to apply suggestion efficaciously,** both with and without hypnotism as a therapeutic adjunct. I give in explanation of those facts, experience and clinical tests as interpreted in the light of modern scientific knowledge.

Many volumes have been written upon this subject by neurologists, scientists, and phsychotherapeutists of note, but in most cases they lack the practicability so essential to its successful employment by the general practitioner. My aim is to emphasize the value of suggestive therapeutics in a field of work that comes within his domain, which has not heretofore been pointed out by the authors of other works of this character. The presentation also embodies what I have assimilated and found practical from a careful study of the investigations of leading authorities on this subject. To make this book practical and easy of assimilation has been my constant aim. And here it may fitly be pointed out, with a view to forestalling criticism, that this book is not intended principally, or even mainly, for neurologists and psychotherapeutists, to whom the constant repetition of what to them are well known facts must inevitably prove wearisome. It is intended rather to instill into the vast mass of the profession to whom this entire field is as yet *terra incognita*, those basic principles of physiological psychology

upon which the scientific therapeutic application of suggestion in all its forms necessarily depends. With that end in view, principles of all pervading importance are iterated and reiterated as often as their application comes under consideration, in order that they may become so fully absorbed and assimilated as to be almost axiomatic to the reader.

To hundreds of American physicians I am indebted for many kindly criticisms and valuable suggestions concerning my lectures and demonstrations, which have been of invaluable aid in laying the foundation for this work. I also desire to acknowledge the valuable assistance rendered by Dr. K. W. Millican of Chicago and Dr. C. R. Lightner of St. Louis in the review of the manuscript for the press, etc.

HENRY S. MUNRO.

AMERICUS, GEORGIA.

PREFACE TO SECOND EDITION.

The author is profoundly grateful to the Medical Profession for the kindly reception accorded the first edition of this book. The exhaustion of a large edition since its appearance nine months ago attests its popularity.

The practability and efficacy of Suggestive Therapeutics, as an adjunct in the treatment of disease, is no longer questioned by physicians who have personally tested the methods herein advocated.

The present edition has a more complete index and has been brought up to date by the addition of new material on those phases of the subject upon which advancement has been made during the past year.

H. S. MUNRO.

ELLAVILLE, GA.

CONTENTS.

		Pages.
Preface.		
Introduction.		
Chapter I.	Hypnotism or Suggestion?	11-15
Chapter II.	Nomenclature Defined	16-20
Chapter III.	Hypnotism Demonstrated	21-43
Chapter IV.	Suggestion, its Uses and Abuses	44-54
Chapter V.	Theoretical Considerations	55-88
Chapter VI.	Other Phases of Personality	89-113
Chapter VII.	Suggestion Applied Without Hypnotism	114-146
Chapter VIII.	Hypnotic Suggestion	147-209
Chapter IX.	The Opinion of a "Neuropath" and Others	210-216
Chapter X.	Some Other Practical Points	217-226
Chapter XI.	The Psychologic Factor in Obstetrics	227-237
Chapter XII.	Training the Subconscious Self: A Rational Basis for Auto-suggestion	238-247
Chapter XIII.	Correct Diagnosis a Safeguard Against Blunders	248-256
Chapter XIV.	Philosophy and Religion and their Relation to Health	257-267
Chapter XV.	Conservation of Energy, Education and Control of the Emotions, Breathing, Relaxation, Dietetics, Etc.	268-276
Chapter XVI.	Roughing It as a Means of Health	277-285
Chapter XVII.	Are All Specialists Egotists?	286-290
Chapter XVIII.	Personality as a Factor in Therapeutics	291-301
Chapter XIX.	The Abuse of Personality	302-308
Chapter XX.	Environment, Its Influence in Therapeutics	309-313
Chapter XXI.	The Brutality of Frankness, Honesty Imperative	314-322
Chapter XXII.	Physical and Mental Hygiene	323-329
Chapter XXIII.	Suggestion in Education	330-338
Chapter XXIV.	Moral Stamina a Therapeutic Power	339-346
Chapter XXV.	Self Mastery as a Fine Art	347-353
Index.		

INTRODUCTION.

It would be superfluous here to do more than briefly allude to the conditions under which this book was written. **The problems of Psychotherapy** are forcing themselves so strongly upon the attention of the medical profession that I do not think that any experience that may throw light upon them should be withheld. About fifteen years ago, while a general practitioner of medicine, I became impressed with the great importance of properly directing the **psychic factor in therapeutics,** and for several years groped in the dark in search of ideas, with such aids as could be gained from the older writers on hypnotism and allied subjects.

Quite an impetus to my efforts was received during a three months' stay in New York twelve years ago, in the personalities of well-known men in the schools of postgraduate instruction in that city, but the far-reaching influence of suggestion or the **personal influence of the physician** as a therapeutic aid in the general practice of medicine was not even faintly appreciated by the profession at that time.

About seven years ago I became convinced that the general profession should have a better understanding of the theory and efficacy of suggestive therapeutics and a knowledge of the practical methods of its administration; and being fully satisfied that the methods which I had **successfully employed in general practice** for several years would be of practical value to all physicians, as an addition to their therapeutic armamentarium, and believing also that this knowledge would be a means by which

they could successfully combat the enormous increase in all the forms of quackery which were at that time springing up as the natural offspring of the rapid evolution in psychological development, I began going from city to city, giving a lecture on suggestive therapeutics, applied hypnotism, and physhic science, limiting my classes exclusively to the medical profession.

The cordial reception and appreciation accorded me in this self-chosen field of endeavor by the more representative portion of the medical profession was beyond my most sanguine expectations, and in all places that I visited the physicians taking my lesson insisted that it be put into a permanent form, to be used by them for future reference.

I was **not yet ready to commit myself** to writing upon this much mooted and misunderstood subject. Within the last seven years, however, the attitude taken by the larger part of the medical profession in regard to the influence of the mind over the body has considerably changed. **The study of psychology** with laboratory instruments and methods has demonstrated the relation between thought and matter in a most convincing manner.

Monism, a philosophy which amalgamates or unifies the two entities called mind and matter, is becoming more popular. **Physiology, psychology** and **biology** are on friendly terms, and harmoniously laboring to solve the problems that are being forced upon all thinking people, as well as physicians.

In contemplating my venture of seven years ago, I now fully appreciate the trite saying of Pope, that "Fools rush in where angels fear to tread." **Be that as it may,** I have been in

association with those of the profession who have studied Psychotherapeutics **in all parts of the world,** and they have made no hesitancy in saying that I had boiled down and crystallized the subject into a readily assimilable and excellent form for practical clinical use. So now, after enjoying the confidence and appreciation of the medical profession as a student and teacher of Psychotherapy, I should deem myself reprehensible and cowardly did I not give my "mite" to help those who need strengthening on this line of advanced professional equipment.

The strong prejudice and open opposition to the free investigation and employment of Psychotherapeutics has exerted an overmastering **influence upon the minds** of many of the members of the medical profession, and many there are who lack the courage and moral stamina to enter this field and employ its truths for the relief of countless thousands of individuals who do not need medicine or surgery, yet are vainly crying to us for help. **While this state of apathy exists** in the ranks of the medical profession, the popular "ists" and "paths" and other disguises are standing with open arms beckoning these discontented and unfortunate ones to come into their ranks and get their Psychotherapy in a placebo capsule of religious dogma or bonepath massage.

I am also fully aware that it is not good policy for one seeking popularity to speak out frankly and honestly upon this subject and tell the truth. Even physicians in many instances who admit that they have made no effort to comprehend the principles of Psychotherapy and apply them as a therapeutic adjunct, feel that any theory or conception or method that does not con-

form to their preconceived ideas, however worn out, moth-eaten and useless, is an insult to their intelligence. Yet, in spite of my **well grounded and justifiable** apprehensions, I now dare to offer this little volume containing ideas, impressions and opinions, based upon conscientious observation, demonstration, tests, and clinical evidence, on the one hand and upheld by the more enlightened element of the medical profession in the leading cities that I have visited, on the other, **perfectly willing** to be ridiculed by those desiring to do so. If I succeed in convincing some part of the profession of the justice of the cause which I defend, and at the same time give others the opportunity of discussing it **with a thorough knowledge of the facts** upon which it is based, this alone will justify me in having undertaken the preparation of this little handbook.

It is not my desire to oppose any system of therapeutics, but to emphasize the importance **of the mental factor** in health and disease, and to point out practical methods that can be applied by the general practitioner as an adjunct to his therapeutic resources.

I fully realize that the ideas herein expressed will be of value only to those who find in themselves that inexplicable psychic response, which amounts to a conviction as regards the truth of the principles elucidated, sufficient to dispel the general unconcerned apathy or half-hearted uncertainty toward the practicability of these methods.

It has been my privilege to get in close touch with my colleagues in towns and cities, in private practice and in hospitals. Here I have studied their problems and been uplifted and in-

spired by their courage and devotion to their work, and have learned to honor and reverence character, manifested in the personality of a physician, as second to nothing in life. In their homes, in their conveyances, in the sick room, and in their private office work, as well as in hospitals and medical societies and colleges, I have been given a cordial welcome, and here I desire to **express again my profound gratitude** for such attentions by turning this little book over to them as a grateful reminder of bygone pleasant relations.

CHAPTER I.

HYPNOTISM OR SUGGESTION?

Hypnotism is the art of persuading an individual to **act upon or execute an idea or a series of ideas,** either consciously or subconsciously. The condition is brought about by suggestion. Thus defined and regarded in the light of present day knowledge, the term has a **significance entirely different** from that generally believed by investigators of twenty years ago.

The hypnotic or suggestive condition is induced with the consent and co-operation of the subject brought under any person's influence, or it is accomplished by playing upon his or her ignorant credulity. **The educational methods in vogue** at the present time in our schools and colleges are bringing to bear upon the minds of our youth the same methods that are adopted when we hypnotize an individual, having first secured his intelligent attention and active co-operation.

The more intelligent person always makes the best subject, just as the best minds take an education—another form of suggestion—more readily. **In both education and moral teaching** the individual is induced or instructed **to act upon or execute an idea or series of ideas,** in order that his life and conduct may be brought under their influence. **All knowledge** on any line is the result of assimilated ideas, and its value is in direct ratio to the extent to which these ideas are acted upon or executed. **The orator or actor** who sways his audience with emotion from

tears to laughter is in the truest sense using hypnotism or suggestion. **The mob leader,** blood-thirsty and murder bent, carries his crowd at the point of emotion in the same way.

From this more modern conception of the meaning of hypnotism, **we all use it unconsciously** every day of our lives, both upon ourselves and upon others. The successful men in every community are those who are persuading others **to act upon or execute their ideas.** This is true of men in all professions and all occupations and branches of trade or commerce. Physicians are no longer afraid to enter the field of physiological psychology and appropriate its truths as therapeutic aids. The possibilities and advantages to be derived from a knowledge of Psychotherapy are appreciated today as never before in the world's history.

In the following pages I expect to lead the reader to see this subject as I see it, and to be persuaded **to act upon a series of ideas and execute them** in relation to his patients in a way that will assist him to help them to get well.

By the use of suggestive therapeutics, results can be obtained where drugs, surgery and other methods of treatment are inadequate. The reading of this book alone by many of your patients will give them all the suggestion needed to relieve certain psychopathic conditions. Our more intelligent patients **have a right** to be taken into our confidence. Many of them are assuming that right and desire to know, aye, they demand that you tell them, why you are adopting a special method of treatment. They want to know what you are giving them and what is to be expected from such measures.

In numerous instances after getting well *en rapport* with my patients, I have educated them into the principles of psychotherapy and turned them away from my care **stronger men or women,** feeling that they no longer need rely upon a physician. Through getting possession of him I have put him in possession of himself. We cannot do our best for our patients without taking into consideration the **higher evolutionary elements of human personality,** call them psychic, mental, intellectual, moral, or spiritual, as you choose.

We are on the threshold of a great awakening to a conscious realization of **a higher conception of our duty** toward our patients and our privileges as physicians. By degrees, step by step, slowly but surely, are we getting away from the superstition that has so long darkened our conception of life. From the time **the little** *amoeba* began to develop by sucking into its jelly self nutriment from the water around it; from the time its little jelly cousin, **the** *moneron*, put out his first pseudopodium, there began the journey toward and the feeling out after a higher conception of life. Long and tedious has been the way, slow and painful has been the ascent from darkness to light. **The law of evolution** in even the lower realm or sphere of life has never mocked an *amoeba* or a *moneron*. The faculties back of the *amoeba* and *moneron* realm whereby they found what they reached out after were no more natural than those that move us to seek a higher conception of life. **The infant** reaches out hand and mouth for food; it is there. The real man, the higher self which is here in a material nursery, **is in the infant stage of**

existence—it seeks to manifest itself in a truer sense. If the little *amoeba* was not mocked, shall he be?

I am a confirmed optimist, it is true, but **in the light of present day knowledge** we are warranted in having a high degree of optimism in regard to the laws of heredity and training. Where there was once an overpowering sense of the infallibility, inexorableness and certainty, of what was called law—of the absolute dependence of phenomena of all sorts, including the supreme one of will, upon visible, tangible, **material elements in the physical body** and its activities—there is now a growing consciousness of self-activity and freedom. **Pessimism as a philosophy** has not the sway that it had yesterday, and we are dwelling more and more upon the will and its privileges as a basis of character and health. We now realize that the mind helps the body as much as the body helps the mind, that both mind and body constitute a manifestation of **the real self in action,** and that every human being has within him an inherent quality of force that he can use for his welfare and happiness.

It may be that the light upon the landscape of the future is but a reflection from the luminous regions of my own hopes, but if we take into consideration **the broader and higher course of human events,** such as the work done by the medical profession in problems of social vice, intemperance, hygiene, dietetics and preventive medicine, sanitation, pure food, etc., we can but feel that we are at last coming to a conscious realization of **a lofty ideal of the brotherhood of man,** and that the day is not remote when the physicians will be found doing all within their power to help their patients to help themselves.

It is now believed by advanced thinkers who have gotten over the stunned and stunning stages of **the light that evolution has shed upon us,** that some individuals of all races have not reached the point of development where the self-conscious ego is capable of taking their lives into their own hands. It is quite likely that this is true. Such people will be helpless dependents upon others to think and do for them as long as they live. There can be **no higher function of a physician** than that of getting such patients to act upon an idea or series of ideas and execute them consciously or subconsciously, in order that their lives may be brought under its influence, and health and happiness be maintained.

The following pages will serve **to illustrate and explain** the position I have taken. I could easily fill this volume with the reports of cases furnishing clinical evidence of the value of Psychotherapy in the routine work of the general practitioner and specialist, but I am fully aware that, after I have elucidated principles and described technique and methods of application, each reader must adapt these principles to **his own personality.**

CHAPTER II.

NOMENCLATURE DEFINED.

By Suggestive Therapeutics, or Psychotherapy, is meant mental influences in the treatment of disease, as applied both with or without hypnotism, with the definite understanding that **any influences** brought to bear upon the mind of the patient, e. g., the impressiveness of the modern static electric machine, the crudest device of the charlatan, including all such methods as are employed by christian scientists, osteopaths, magnetic healers, and divine healers, as well as the influence **exerted in any way** by the personality of the physician in words of encouragement, reasoning, persuasion, advice, etc., **all come under the broad domain** of Suggestive Therapeutics.

Any mode of influence exerted by a human being by any means whatsoever for therapeutic purposes conforms to the same general law. When we understand Suggestive Therapeutics we know the why of all the cures brought about by all so-called mysterious methods in both ancient and modern times. **The miracle of the past** is the fact of today, and what was regarded in ancient times as a miracle was a result of the employment of some law at that time, and perhaps even now, not understood.

Suggestive Therapeutics is the only form of mental therapeutics that is **based upon scientific principles,** and is not in open opposition to other rational therapeutic measures. It is regarded

simply as **a therapeutic resource** and not as a complete system of medicine, though with it cures can often be brought about **where other methods have failed** and even when used alone, other therapeutic measures will frequently be unnecessary.

In Suggestive Therapeutics, or Psychotherapy, we make use of hypnotism. By the aid of hypnotism it is possible to exert a greater influence upon the mind of the patient than can be done through any other agency. But suggestion is of great value in the treatment of disease without the aid of the deeper suggestive condition called the hypnotic state, By suggestion in that state, or in that suggestible condition known as the hypnotic state, however, results can be obtained that cannot be obtained by suggestion without that condition. I have demonstrated and proved that proposition to **several thousand American physicians,** and I confidently expect the facts set forth and demonstrated here to remove the least shadow of doubt from the reader's mind upon this question. Simple suggestion, however, will be used ten times in the practice of medicine for each occasion on which it will be necessary to resort to actual hypnotism. Yet I insist that it is the **same treatment in kind,** with a difference only in degree as regards results. By the aid of hypnotic suggestion results are obtainable that cannot be obtained in the general practice of medicine in any other way.

Hypnotism Defined.—**Hypnotism,** as we saw in the last chapter, is nothing more than the getting an individual to **act upon or execute an idea or a series of ideas,** either consciously or subconsciously. Whenever an individual can be induced **to act upon a suggestion** in any department of life in that sense, then

he is, strictly speaking, hypnotized; but for our **present purposes,** let us regard hypnotism as being the induction of a mental and physical condition in which the subject is **more amenable or susceptible** to suggestion at the hands of another, and possesses an increased ability to carry out that suggestion. In this condition **a greater influence** can be exerted over the mind and body of the patient. It is the induction of a suggestible condition. By suggestion in the hypnotic state, powers and potentialities lying dormant and unused in the patient can be brought into play. A consciousness of those potentialities can be awakened in him. He is thus introduced to a new element in his own life, be it physical, mental or intellectual, or moral, and that can be accomplished by suggestion for the patient which cannot be done by any other means.

The cases reported by Dubois, which he describes in high-sounding, neurological phraseology, are just such cases as compose nine-tenths of the work of every general practitioner in the United States; and there are thousands and thousands of American physicians who have not one-fourth the verbosity wherewith to describe it who are using their own individual methods of Psychotherapy in this class of cases with equally good success. We all use suggestive therapeutics every day of our lives, either consciously or unconsciously.

I desire to introduce you to **a higher conception of this subject,** one that is distinctly American, one that has **struck a responsive chord** in the character of the more enlightened element of the American profession, hundreds and hundreds of whom have studied this subject in Europe and have witnessed European methods of applying suggestive therapeutics.

Suggestion Defined.—You have no doubt observed that I use the terms "hypnotism" and "suggestion" as synonymous terms. Any idea or hint or intelligence or impression made upon the mind of an individual is a suggestion. Usually, however, when we use the term suggestion, we mean an oral suggestion. So to make myself clear I will define suggestion to mean **what you say** to your patient, and **the way in which you say it.** It embraces everything in the personality of the physician and his conduct in the sick room.

Suggestive Therapeutics, then, is the **sum total of the influence** exerted by the physician on his patient to help him toward recovery, or for the relief of any mental or physical symptoms of whatever kind; and, as we shall see later, this is always accomplished through the **normal physiological processes.**

Pardon me for being so explicit, almost prolix, in the definition of terms, but I desire thus to make plain my point of view of this subject at the outset, and at the same time to utter a protest against **the lack of moral courage** that some individuals have assumed toward hypnotism and suggestion, while attempting to hypnotize or suggest the profession into believing that they use an entirely different method and employ neither hypnotism nor suggestion!

It is the duty of every physician who is true to his Hippocratic oath to adopt and use every measure that will alleviate human suffering. A little deception in one sense is used as a therapeutic measure **by all physicians,** and anyone who denies this is yet in the embryonic stage of his appreciation of the psychological factor in therapeutics. But it should be expected

of medical men, in discussing means to secure an end for the greatest good of their patients, to **be absolutely honest with each other,** as becomes men who are members of a high and noble profession.

"**Psychotherapy** is **suggestive therapeutics,** and it is applied in many different ways according to the requirements of each individual case," as Forel concisely remarks.

Pre-Hypnotic Suggestion.—**Prehypnotic suggestion** is the mental preparation of the patient to be hypnotized.

So much which would have the effect of **prejudicing the lay mind against its employment** has been done and said and written upon hypnotism in the evolution of this subject, through the ignorance and superstition of the last one hundred years, that you will find that the best results will be obtained when you conceal from the patient the fact that you are using hypnotism or suggestive measures, until after you have obtained therapeutic results. **Then you may explain** what you are doing and why, and the patient will appreciate your efforts. In some cases I make no explanation because the patient is incapable of understanding it. **There is a prejudice, a fear, an antipathy,** a skepticism, toward the use of hypnotism in the minds of some of the laity to such an extent that you will succeed with suggestive measures just in proportion as you cover them up with some other name or theory, **as is done by the christian scientist, the osteopath, the magnetic healer, the religious revivalist, the patent medicine vendor and the health food manufacturer.**

CHAPTER III.

HYPNOTISM DEMONSTRATED.

I will describe to you now a method which I have used in connection with my class work with physicians on **nearly four thousand subjects,** with the result that practically every one who gave his consent and co-operation was hypnotized, without failure, I am sure, in one per cent of the cases.

Instead of appearing to use hypnotism in the presence of the physicians on the individuals brought in for demonstrations, we use a medicine in a bottle, one of the local antiseptic solutions, and call this medicine **"Somno-Analgesic Compound."** We ascribe to this medicine whatever value or therapeutic property we desire it to possess, and **picture on the mind** of the individual what effect it will have, and getting his consent for us to use the medicine, we secure all the co-operation necessary on the part of the subject to put him into that suggestible condition which **is produced by suggestion** and known as the hypnotic state—the most unfortunate term, so far as the successful application of suggestive therapeutics is concerned, that could ever have been devised.

Some people will let a "medicine" put them to sleep, quiet them, influence them, relieve their pain, even though it be only **a little bottle of pure water** that we call "Somno-Analgesic Compound," but they are alarmed at the bare idea of hypnotism or suggestion. **They will stand for Dubois** to use his "moral ortho-

paedia," "reasoning," "persuasion," etc., while he unconsciously hypnotizes them into **acting upon an idea or series of ideas,** and executing them both consciously and subconsciously, as his reports show. People who will not stand to have the truth explained when one attempts to show them that **all forms of mental therapeutics** are based on sound, sensible, rational principles of physiology and psychology, will allow **the christian science teaching** to hypnotize them into an attitude of denial of pain, sickness, and death, on the one hand, and into a mental attitude of affirmation, iteration and expectancy of health and happiness on the other. **A very excellent form of suggestion** they have, based on a theory that is one-half truth only, but with that one-half truth they get results.

If you were to ask me **how to make a suggestion,** I would say, "In a perfectly natural way of talking, with the least affectation possible." If you in the least doubt your ability to use the method which will be explained to you here, **be actor enough** to speak and act as if you had not the slightest doubt about the results to be obtained. **Talk as if you meant it,** talk calmly, earnestly and kindly. Use a monotone voice. Look at your patient while you are talking to him. Look right into his eyes and get him to look at you.

The following demonstrations and explanations were stenographically reported showing in detail my method of demonstrating hypnotism in my class work among the physicians. There were **present several well-known physicians** who took part in the demonstration described, who will vouch for the correctness of the incidents here reported.

When we were ready for material for the demonstrations of hypnotism, **two of the physicians** present were requested to **go out on the street** and bring in two or three men who were absolute strangers to us all.

The method here described demonstrates a simple, practical, efficacious method of inducing the hypnotic state to the extent that anaesthesia can be produced, and **each one of the several physicians** present demonstrated his own ability to do so, using an entirely new subject, brought in from the street, whom we had never seen before. **The physicians bringing in the men** obtained for demonstration purposes were requested to seat them in the ante-room. One of them was brought into the room at a time, to be hypnotized, and as he walked in at the door I addressed him as follows: (Take note that the medicine used upon this occasion was only a small vial of water.)

A Pre-Hypnotic Suggestion Given.—"**Take this chair, please.** Now, I will explain to you what I am doing and what I wanted with you. Do you see this little bottle of medicine? This is a sample of a preparation that I am introducing to the physicians, known as "Somno-Analgesic Compound." "Somno" means sleep producing, and "analgesic" means pain relieving; so, then, this is sleep-producing and pain-relieving medicine. It is used by rubbing it on the forehead just as you see me rub it on mine. You notice it does not harm me and it will not harm you. Now, I have explained to the physicians here that, in order for this remedy to have its effect, it must be applied in a certain way, and that **it is the way that we get our patient to do and be** while the medicine is applied,

Fig. 1.

A Condition of Voluntary Receptivity.

Before beginning suggestions to induce hypnosis, after giving pre-hypnotic suggestions, have your patient relax every muscle, close his eyes lightly and breath through his mouth, as illustrated in the above cut.

---

that determines its effect. I want you to take a seat in this chair, **lean your head back against the wall, relax every muscle, close your eyes lightly, and breathe through your mouth,** just

as if you were going to sleep. Then, as I apply the remedy, you will soon get quiet all over, then get drowsy and sleepy, and go to sleep, and awake feeling better. Now, see here, my man, **don't resist the effect of the medicine;** just sit here and **let it have its effect."**

Suggestions to Induce Hypnosis.—"All right, take this seat. Lean your head back against the wall. **Close your eyes lightly and breathe through your mouth and think of going to sleep.** Now, as I apply this remedy you will soon become quiet all over and get drowsy and sleepy, and go to sleep, and awake feeling better.

"I will talk to you to help you to concentrate your mind. Now, as I apply this remedy, you will get sleepy, sleepy, sleepy, so-o-o-o sleepy. Now, go to sleep, sleep, sleep, sleep.

"Now, you feel quiet all over. Your muscles are relaxed. Everything is dark to you. You do not hear anything but my voice. You are drowsy and sleepy, so-o-o-o sleepy. You feel the sleep coming over you. You are going to sleep. Sleep, sleep, sleep.

"By the time I count ten you will be **fast asleep.** One, two, three, four, five, six, seven, eight, nine, ten, and you are asleep, fast asleep, sound asleep.

"By the time I count **five more** you will be **sound and dead asleep,** just as you are in the dead of night when sleeping soundly in your own bed. One, two, three, four, five, and you are asleep, fast asleep, sound asleep, **dead asleep.** Don't awake now until I tell you.

"Every second your sleep will become **sounder and sounder** and deeper and deeper. Sleep on quietly until I awake you.

"Now, you will not feel anything or hear anything or know anything except what I tell you. Sleep on quietly until I awaken you."

"Now, gentlemen, this subject is **in a suggestible condition,** which I will proceed to demonstrate. I raise his arm.

Suggestions to the Subject Hypnotized.— **"Sleep on quietly.** When I count three this arm will be stiff, so stiff that you can't take it down. One, two, three; your arm is stiff, and you can't take it down until I tell you. Now, **when I rub this medicine on your arm** three times it will be dead and have no feeling in it. **Now, I pinch this arm"** (thrusting a pin through a fold of the skin), "but you do not feel it; there is no feeling here at all; this arm is perfectly dead."

"Gentlemen, **no one minds being pinched,** at least with your finger nails, so I give the easiest suggestion to accept, to accomplish an end. For the same reason I say to a patient, 'I will **examine this tooth,'** while in reality I apply the forceps and extract it. This makes it easier for the patient to accept the suggestion."

"Now, sleep on, and when I count three, stand up. Put your heels together, and when I say "stiff," **be as stiff as iron, so stiff I can lay you across two chairs and you will not bend.** One, two, three. Now, stand up! Get stiff, stiff as iron."

"Place his heels in the other chair, please, doctor." (The man is placed with his head on one chair and his heels on another.) "Now, hold strong, be stiff." (Standing upon his

body.) He sustains my weight of two hundred pounds easily. "Now, relax, limber, sit down and sleep on."

"Now, my man, when I count three you will open your eyes and be wide awake. **You will be feeling good all over.** You will remember nothing that has been said or done, and will find that you **never felt better in your life,** and will always be glad that you came up here. One, two, three, and you are awake."

"Have a good nap?"

"Yes, sir."

"What do you remember since coming into this room?"

"Nothing at all but sitting in that chair and going to sleep."

"You are sure that nothing has hurt you since sitting there?"

"No, sir, nothing has hurt me."

Now, **the talk that I gave that man** about my selling the medicine, and how it was used, and what it was used for, etc., was **the prehypnotic suggestion.** In that way I got his **voluntary consent** to sit in this chair and let the medicine have its effect. In doing that, he was letting me put him in that suggestive condition unfortunately named the hypnotic state. Notice again, **I had that man relax every muscle, close his eyes lightly, and breathe through his mouth.** He was then in a condition of **voluntary receptivity.** The very fact that he agrees to relax, close his eyes, and breathe through his mouth, indicates that he is a hypnotic subject, **because it signifies his willingness.**

As to who is a hypnotic subject, it is the individual that does not know that he is to be hypnotized, whose confidence I can secure sufficiently to get him to conform to the conditions,

just as we have demonstrated. I always **secure the voluntary co-operation of the individual** and get that supreme factor in human consciousness, the will, to assist me in accomplishing the result. I get the co-operation of the **voluntary waking consciousness** to act upon or execute an idea or series of ideas, either consciously or subconsciously. In getting an individual to go into **that sleep-like condition** known as the hypnotic state, I am simply getting the real ego to **act upon or execute an idea through intelligent co-operation.** That is the way by which that subconscious condition known as the hypnotic state is produced. Then, **after the subject is hypnotized,** I get him to act upon or execute an idea subconsciously.

In over four thousand instances in which I have used men of all nationalities for demonstration in my class work, I have yet to see the **first unpleasant result.** In all cases pins were stuck through their faces or arms and their bodies put across chairs and one or more men stood upon them. I have used **lawyers, preachers, doctors, dentists, merchants, mechanics** and people of all trades and classes. As regards nationalities, Germans, French and English, Italians and Chinamen, Japs, Indians and negroes, have been my subjects. They have all proved about equally susceptible as regards race.

The more intelligent individuals of all races made the best subjects.

Everyone that left the room went out with a pleasant smile on his face, and most of them thanked me for the experience. I treated them all kindly and acted in a way to secure the co-operation of a high element of human consciousness.

One exception should be mentioned where we had a little variety. In Colorado Springs a man came in drinking and I suggested that he was getting sick, **suggestion without hypnotism,** and that he was going to vomit, and he did vomit, copiously. In giving him a suggestion to relieve him of this condition, after suggesting that he was feeling easy and comfortable all over, and that his nerves were steady and quiet and strong, I suggested that he was feeling fine, and would go out **feeling like a fighting cock.** I walked out behind him into a dimly lighted hallway to tell the man securing men for demonstration purposes not to bring in another drinking man, when this ruffian, a miner weighing about one hundred and ninety pounds, both tough and strong, began to **exhibit his fighting cock qualities on me.** After flooring him, which was necessary for self-defense, I got him into the room, but secured his release from arrest by exacting from him a promise **never to hit an old man or a little boy** when he wanted to fight, but to always hit a man just like me. This he promised, and with my arm around him I led him to the door with the injunction to be good and quit drinking.

In this case we had a demonstration of the efficacy of **simple suggestion** on the one hand, and of **"forced suggestion"** on the other. I suppose Dubois would have styled that **"moral orthopaedia."** Many men, when drinking, are **very amenable to suggestion** without hypnotism, and so is a drinking woman, but you can never get an individual to accept a suggestion that **is not in accord with his character. Self suggestion** is always stronger than the suggestion of another, and the home training,

moral conviction, religious influences, etc., all go to form a self-suggestion in the individual **which is the basis of character,** so that the individual will never accept a suggestion not in accord with, or that antagonizes, his own autosuggestions.

People have faith in medicine, and when we proceed as if using a medicine, we utilize the faith or confidence that is reposed in this material agency, inert though it is as to physiological effect, which proves a **most powerful factor** in producing that condition known as the hypnotic state, on the one hand, and getting results by suggestion applied as a therapeutic measure, on the other.

This was illustrated for me once, when a woman brought a seven-year-old child to my office in a great hurry to get something done very promptly that would prevent a small silver coin that he had swallowed from killing him. She had frightened the child badly. After drawing the attention of the child away from itself by showing some curios in my office, I said to the little fellow, **"Now you feel all right, don't you?"** "Yes, I am all right," was his reply. I then turned to the mother and set out to assuage her fears by telling her that there would be no danger to the child from swallowing the coin, that I had swallowed a coin when a small boy and it did not hurt me. That I had repeatedly had children brought to me who had swallowed a coin and it never did any of them any harm at all. That her child needed no castor oil, which she was about to give it, or anything else but to be let alone. When I arose to turn her out of my office, she exclaimed in a most emphatic manner, **"Why, doctor, are you not going to give him any medicine?"** I saw at

once that it was impossible to reason with that woman, so I said, "Yes," and forthwith prescribed one ounce of compound rhubarb and soda mixture, and handing it to her, directed that she **give ten drops of this every two hours,** and that I would guarantee that inside of a week he would expel that coin all right and never suffer the slightest inconvenience. She received more satisfaction **in two minutes** from that prescription than from a ten-minute conversation in which I had reassured her all that I could.

Our therapeutic measures must be **in accordance with an individual's preconceived beliefs.** I notice more patients in the office of a physician who uses medicine as a means of satisfying the mind of his patient, as well as persuasion, reasoning, advice and other forms of suggestion, in conjunction with the placebo prescription, in one day than I do in a week in the office of a physician who entirely relies upon **"therapeutic conversation."**

In another similar case, the mother was perfectly satisfied when I advised that her child eat a baked potato with his meals three times a day, stating that this would conduct the coin to a safe delivery without the slightest harm to the child.

Our therapeutic measures must be **adapted to the individuality of the patient** with whom we are dealing.

Demonstration No. 2.—"Now, Doctor Blank, I want you to hypnotize the next man. I want you to **convince yourself that your suggestions** are just as efficacious as mine.

"See, I have **tacked these printed suggestions upon the wall,** over the chair that the man will occupy here. I will give him the pre-hypnotic suggestion for you. By this I convert him into

a hypnotic subject. **I talk him into willingness** to sit in that chair and **let the medicine** have its effect, while you carry him, by reading those suggestions on that wall, into a deeper state of suggestibility. Bring in another man, please." (Another subject is brought in.)

A Pre-Hypnotic Suggestion Given.—"**Take that seat** and I will explain to you what I am doing and what I want with you. Do you see this little bottle of medicine? I am introducing to the physicians here a remedy to cure headache, quiet nervousness, relieve pain, etc. It is applied by rubbing it on the forehead just as you see me do here. It must be applied in a certain way to get results. The physician here knows how to apply it. I have explained to him that it is important **to get his patient to conform to certain conditions** in order that the medicine will produce results that are expected. That is what I will show you. I want you to sit in this chair and let the doctor apply this to you just as if you had a headache and he were going to relieve it for you. Now, look at me. I want you to sit in this chair as you see me, **relax every muscle, close your eyes lightly** and **breathe through your mouth.** Then when the physician here applies this remedy, you will soon get quiet all over and get drowsy and sleepy and go to sleep, and awake feeling better. Now, I want to ask you, **don't resist it,** just sit here and allow the medicine to have its effect. Take this seat." **"Proceed to apply the medicine,** doctor." (Rubbing "the medicine" on his head on either side, the physician read the following suggestions in a **conversational tone, with a low monotone, affirmative voice**):

Suggestions to Induce Hypnosis.—"You close your eyes lightly. **Breathe through your mouth.** Think of going to sleep. As I apply this remedy you will soon get quiet all over, and get drowsy and sleepy and go to sleep and awake feeling better.

"I will talk to you to help you concentrate your mind.

"Now, as I rub this on your head you will get sleepy, sleepy, sleepy, so-o-o-o sleepy. Now go to sleep, sleep, sleep, sleep. Now you feel quiet all over. Your muscles are relaxed. Everything is dark to you. You do not hear anything but my voice. You are feeling quiet from your head clear down to your feet. You feel a torpor all over your body. Your arms and limbs are so-o-o-o heavy. You are drowsy and sleepy, so-o-o-o sleepy. You feel the sleep coming over you; you are going to sleep. Sleep, sleep, sleep, sleep.

"By the time I count ten you will be fast asleep. One, two, three, four, five, six, seven, eight, nine, ten—and you are asleep, fast asleep, sound asleep.

"By the time I count five more you will be sound asleep and dead asleep, just as you are in the dead of night, when you are at home on your bed,—one two, three, four, five—and you are asleep, fast asleep, sound asleep, **dead asleep. Don't awake, now, until I tell you.**

"Every second you sleep will become sounder and sounder and deeper and deeper. You now see what a quiet, sweet experience you are having. You are having a quiet, refreshing sleep. **Sleep perfectly quiet until I awake you.**

"Now you will not feel anything or hear anything or know anything except what I tell you. Sleep, sleep, sleep, quiet, refreshing sleep. Sleep perfectly quiet until I awake you. Every second you sleep will become sounder and sounder, deeper and deeper. **Sleep on quietly until I awake you.**"

I then proceeded: "Now, doctor, hold up this man's arm and suggest to him that when you count three it will be stiff, so stiff that he cannot take it down." (The arm staying there as suggested **indicated that the individual was in a suggestible condition.**) "Now, take hold of his wrist, doctor, and say to him, 'Your arm will come down now.'

"You notice that arm came down with **a wax-like resistance,** no volition exercised by him at all. When I feel that **wax-like resistance** as I make the 'arm test,' I am quite sure that I **can produce anaesthesia** by suggestion.

"Doctor, suggest to him that his arm will be dead when you rub the medicine on it three times, that it will **be perfectly dead** and **have no feeling in it** at all. You see, gentlemen, after that suggestion I am able to thrust a pin through his arm without the slightest evidence of pain."

(Doctor Blank asks if **any other part of the body** can be rendered anaesthetic by suggestion, and if it is not a fact that the back of the arm is neither very sensitive nor vascular.) "All right, rub some of this medicine **on his lower lip** and suggest that when you rub it three times it will be dead and have no feeling in it. Notice this, please, gentlemen." (Thrusting a pin through his lower lip from outside to inside an inch through the

lip.) **"You see it does not bleed,** even on the inner surface of his lip."

No place except the eye is more sensitive than the lip and no place in the body is **more vascular.** As to why this does not bleed, I will refer later on in my lecture. It is supposed to be the influence exerted by suggestion upon the co-aptation of the neurons.

Upon one occasion in the presence of the faculty of Tulane University, and of at least one hundred physicians and three hundred medical students, I thrust a steel hatpin through **the cheeks of three hypnotized subjects.** Then I requested a noted surgeon there **to name one man's face** that should bleed, and bleed more than just a few drops, and that I would remove the pin from the faces of the other two men **without bleeding,** while this man's face would bleed. The experiment was a perfect success. I made the same experiment in Mobile, in the presence of the Medical Society there.

The method of **getting the part to bleed** is to suggest pain in the part, and the control over the blood supply to the part through **the influence of the higher centers** over the vaso-motor neuro-regulation of the blood supply is augmented. **To keep it from bleeding,** suggest that the part is dead, perfectly dead, and has no feeling in it. Then the higher centers seem to exert an inhibitory influence over the flow of blood in the part, with which in suggestive anaesthesia, the face pierced by a steel hatpin does not bleed, at least in nine-tenths of the cases.

"Your subject seems to be comfortable, doctor. Now, suggest to him that when you count three he will stand up,' and

when you say 'stiff,' that he will be as stiff as iron from head to foot. I will lay him across the chairs for you, as there is a knack that I have acquired of lifting a man in that position that makes it easy for me.

"Put your foot there, doctor, and **we will both stand upon him.** Give me your hand. Tell him to be stiff! to hold strong! Now, come up gradually.

"You see, **he easily sustains our combined weight** of over four hundred pounds in a line in the center of his body.

"Tell him to **relax. Sit down. Sleep on.** Doctor, suggest to your subject that when you rub this medicine on his arm three times it will **be dead and have no feeling in it** as long as he is in this room. Tell him that **when he is awake** you can thrust a pin in the skin of that arm while he is looking at it and he will have no feeling in it, that his arm will be **perfectly dead** as long as he is in this room.

"Now, suggest to him that when you count three he will be wide awake, that **he will feel good all over,** that he will not remember anything that has been said or done while in the room, that nothing has hurt him, and that he will **never have felt better in his life,** that he will be glad he came up here and will always feel better. Now, count three and tell him to awake."

"All right, my man, how do you feel?"

"All right, sir."

"Has anything hurt you since you came into this room?"

"No, sir, not in the least."

"Do you see this pin?" The doctor put some medicine on your arm here and it has no feeling in it. I am going **to stick it with this pin.** If you feel it in the least, let me know. Now, look at it, here it goes; **do you feel that?"**

"Not a bit."

"That will never hurt you or never get sore in the least."

(The doctor asks if we ever have **any trouble in waking** a subject?) "Not in the slightest. He is in a condition of increased suggestibility, and to awaken him is only to get him **to act upon an idea or suggestion,** and this he will do easier now than ever before, provided you make the suggestion properly.

"Occasionally it is necessary to repeat again, 'Wake up.' **Rarely have I found** it necessary to thump him on the face or slap him lightly and speak more emphatically, 'Wake up!' Be calm, well poised, and self possessed. Should you ever find a subject that anyone else had hypnotized and found difficulty in awakening, either turn an **interrupted current of electricity** upon him or administer one-tenth of a grain **of apormorphine** hypodermically, and see what he will do. **I have never found this necessary."**

What effect does hypnotism have on the subject, is asked. "Whatever effect you suggest. The effect is determined altogether by **your suggestions.** Hypnotism is but the induction of a mental condition in which your suggestions will be more effective and lasting. I will cover that question in detail in my analysis of the subject later on.

"Gentlemen, you notice those men go out of this room **with smiles on their faces.** They seem to appreciate and enjoy the

experience. The higher evolutionary element of human personality has in them **been put to a test.** They have proved their mastery over the physical man. Call this intelligence, **will, or reason,** as you choose. It functions with the mind and is a **psycho-physical process.**

As these experiments are conducted here I regard our demonstrations as splendid mental gymnastics. Those men are sent out of here with a new element of selfhood having been aroused within them. **The real man, the ideal ego,** is more self conscious of his mastery and control of mind and body, his servants, than when he came into this room. I never hypnotized an individual in my life who **was not my friend after that,** all because I dealt with him kindly and he appreciated it. **The man himself,** the real self, is not weakened and dethroned by the methods that we employ, as some would have you believe.

When you rightly appeal **to the higher self,** you can take that old physical hull, his body, and stick it, stand upon it, cut it, etc., and it is all right with the master of that house, or physical body, because every step you are taking is through **the power possessed within him.**

How frequent it is that **the operator becomes hypnotized** instead of his subject, thinking that it was some power that he was exerting over the hypnotized individual, rather than the use of an inherent quality of force **within the individual himself.**

It is largely a matter of confidence in human beings. **Faith in your fellow man,** confidence in his ability to exercise inherent potentialities that are written in his blood, and chiseled in his cerebral cells, is the secret of success in this line of work, as well

as **an important essential** in rendering genuine service to your fellow man in every department of life.

(**Demonstrations Nos. 3, 4, and 5** were about like those just described, and a further report of these cases is therefore unnecessary.)

"Gentlemen, with **the next subject waiting** on the outside, I will demonstrate another method of inducing the hypnotic condition by having him **fix his eyes** upon some bright object, so as to get his attention while making suggestions.

"Take this seat, my man. These are physicians and I desire to show them how I can get a man to look at this bright collar button until his eyes become tired and how he will go to sleep in a few minutes. I will put you to sleep and you will sleep not over five minutes and awake feeling better."

"But I do not care to go to sleep, doctor," says the patient.

"All right, then, we will excuse you."

A physician: "Doctor Munro, I should like to see you put that man to sleep and put him through the same test as you did the others."

"I should be glad to do so, doctor, but this man says he does not care to go to sleep and that is the end of it so far as our efforts to hypnotize him are concerned. **No one can be hypnotized against his will.** Consent and co-operation are absolutely necessary, except where auto-suggestion on the part of the patient can be brought into play through credulity or fear—conditions which would remove the experiment altogether from the realm of the justifiable.

The point that I have attempted to **drive home** upon your consciousness here is that more people will consent for **the medicine** to put them to sleep than will give their consent to be hypnotized; so by the use of the medicine you can accomplish results **that cannot be secured otherwise.** It is a means to secure an end. **There is no deception in it,** for I tell the individual what I expect **him to do,** what **will be the result,** and what I want him to do in order that the result may be obtained. **The medicine actually** is the material means through which the effect is induced. It does it by the impression it makes upon the mind, the sensory nerves, if you please, and this impression reaches and influences the higher cerebral centers. It accomplishes its work in accordance with the **normal physiological processes.**

It may seem queer to you at first glance that we can influence the physiological processes **by psychological methods.** But all medicines produce their results by their influence upon function, even when taken into the stomach or applied hypodermically. **Medicine used locally** as a means of suggestion is a powerful functional stimulant. By it we can inhibit certain brain centers and call into play an increased activity of others. We quiet nervousness, we relieve pain, we restore sleep, we encourage secretion, nutrition and excretion.

All therapeutic measures can accomplish their results only by acting in conjunction with those inherent properties and forces within **the biological element of the organism.** Our internal medication only acts upon function. **Medicine used internally or externally,** whether for its physiological or psychic

effect, can through the suggestion giving it its psychological potency, stimulate the function of every organ in the body.

Every center of activity in the brain can be influenced by suggestion. Every organ in the body and all bodily functions are under the control of the nervous centers. **Every element of the organism** has its center of activity in the brain. All these we can influence by suggestion, and we can use medicine and surgery and all other therapeutic measures, **not only for the effects produced by their own physical influence** upon the organism, but also as a means of successfully combating the disturbing psychic factor through **the influence of those measures** upon the mind. Every physician uses these measures, consciously or unconsciously, every day of his life.

Do not understand by the ground that I have taken that I am a therapeutic nihilist. I am **first and last a regular physician,** anxious for any therapeutic aid by any means whatsoever that will help to alleviate human suffering and cure disease. **We can demonstrate** the physiological action of our medicinal agents upon the physical organism, even in unconscious persons and animals, as impressively and conclusively as by a slap or a kick we can demonstrate to the person who denies it our ability to use our hands and feet.

But understand, I am talking to you about the **psychic factor in therapeutics,** pointing out its value as an important therapeutic adjunct, to be used in conjunction with any measure, medicinal, surgical, or otherwise, **that will help to alleviate suffering** and cure disease, or that will put the individual in such condition that a cure may take place.

This science as applied in the practice of medicine is based upon these premises: There is **inherent in mankind** a psychic power or mental force presiding over the functions, conditions, and sensations of his body, and this inherent potentiality, **which is a property of the cells** that compose the complex mechanism of the animal physiology, can, under proper conditions, be **evoked** and **controlled at will** and applied to the alleviation of human suffering.

WHAT that inherent quality of force represented by each individual cell in the human body is, has in ages past been called by many names. It has been designated by such expressions as the **"vis medicatrix nature," "the resident energy within," "neuric energy,"** and, in the terms of psychology, **"the subconscious mind," "the subjective mind" "the subliminal consciousness," etc.**

Tennyson referred to the same incomprehensible life principle when he pulled **a little flower from crannied wall** and said:

> **Little flower**—but **if** I could understand
> **What you are,** root and all, and all in all,
> **I should know** what God and man is.

The tendency of modern science is toward **the possibility of reducing all phenomena,** physical as well as psychical, to a common cause.

Verworn remarks that "The attempt to explain the mystery that surrounds living substances, the substance that nourishes itself, breathes, moves, grows, reproduces and develops, **has exerted from the earliest times** a peculiar stimulus upon the mind of inquiring thinkers."

But while **we do not know** what that inherent quality or force as represented by the individual cell is, neither do we know **what electricity is,** nor what matter is, in any form in its ultimate analysis, **but we do know something,** not all, of the laws that govern these of Nature's forces, and by conforming to these laws we are better enabled to make our struggle for existence.

By conforming to this psychological law, we can get results in the alleviation of human suffering, and as broad minded men we want to make use of anything that will help us **to grapple with the problems of health and disease.**

Just as **steam and electricity** were governed by Nature's laws that existed forever and only required science to make use of them, **so has psychic law existed forever,** and a better understanding of, conformity to, and appropriation of this law are destined to make the same revolution in the practice of medicine as has been effected by steam and electricity in methods of **travel, manufacture and communication.**

The intelligence of our age demands that the higher evolutionary factors of human personality, call them by whatever name you will, be recognized, and **their truths be appropriated** for the welfare, health, and happiness of our patients.

CHAPTER IV.

SUGGESTION, ITS USES AND ABUSES.

This is an age of dynamics. It is a day when all minds are turned in search of laws that govern hidden forces. The intelligent comprehension and utilization of Nature's forces, through compliance with the laws that govern them, has revolutionized the external world of travel, manufacture and communication. **Step by step,** humanity is entering upon the field of finer forces. Electricity, a force unseen, through intelligent compliance with the laws that govern it, is utilized as never before for the comfort and happiness of man. **Man's progress in the scale of evolution** has been in just that degree that he has utilized forces governed by laws not understood and has appropriated them for his happiness and welfare.

We are in this world for growth, and to help raise humanity in the scale of evolution is the only worthy purpose of all human endeavor and achievement. Each individual represents just so much energy, and by his use or abuse of this inherent life force is he a factor for good or evil. **A better understanding** of the laws governing the power that we are all using, either ignorantly or intelligently, should be a means of helping each individual to use his life forces for the advancement of self and

for the good of others. **The struggle for the achievement of happiness and health** is the greatest incentive to the activity of the human race.

Evil is simply the result of misdirected energy. The universe was made for man, and all the forces of Nature are **beneficent** and are placed here for his utilization. By perfect conformity to Nature's laws, health and happiness may be maintained; but for violation of, or opposition to Nature's laws, disease, impotency or premature death is the penalty.

In the study of hypnotism and the laws that govern its application we are led into the study of the laws governing and controlling the mind and its influence over the physical organism. **Suggestion,** or an idea aroused in the mind of the subject by impressions from without, or conveyed from one mind to another, is found to be the dominant factor in producing the psychological condition known as the hypnotic state. **Perhaps no one subject** has been so much abused as the subject of hypnotism by the very class of people who use the all-potent factor, suggestion, which they either ignorantly or maliciously deny, as the force by which most of their results as curative powers are obtained. I refer to **christian scientists, weltmerites, faith healers, and such like. To point out the danger** which attends the unconscious and ignorant use of suggestion, both with and without the aid of hypnotism, **as well as the possibility of benefit** that may accrue from its intelligent use as an adjunct in the practice of medicine, is my purpose .

Suggestion is an impression conveyed by any means of communication whatsoever from one mind to another. It has been

used by every human being, profession, school of learning, sect, "ist" or "ism" that ever existed. **All education** is the result of repeated and accumulated suggestion. **All theological sermonizing, dogmas** and **religions,** make employment of suggestion upon the mind. **Our belief** upon any subject is the result of dominant suggestion. **By our use or abuse** of our powers of suggestion do we become a force for good or evil.

So receptive is the human mind to suggestion, that we become **a part of all** with which we have associated during our existence. Our beliefs or convictions upon any subject are **the sum of the suggestions** that have possessed us.

By suggestion we are enabled to **build character** in those susceptible. Its use is of inestimable value for the **correction of vice, the cure of evil habits,** and the prevention of certain forms of insanity. By it the **will power is strengthened,** latent talents are developed, and inherent capabilities of mind and body brought into activity.

By the use of suggestion **brain centers can be stimulated** and brain cells developed. **Virtue can be instilled** and vice eradicated; purity or impurity, confidence or fear, love or hate, joy or grief can be made the **dominant quality** of the mind.

By suggestion we exert personal influence which stirs human activities and is a tremendous power for good or evil in the universe. By this **all available energies** or forces of Nature are being controlled and utilized for the happiness of man.

By suggestion every center of activity in the brain can be strengthened and every organic function in the body increased or encouraged to new activity. **War and bloodshed,** theft and

wreck and ruin of manhood and character, are the result of evil suggestions that have been allowed to dominate the mind of an individual or a nation.

The most sacred shrine of the soul itself is invaded, dominated and profaned by suggestions intruded upon the individual in which the ideal ego has not been awakened and evolved.

Suggestions are forces operating in the realm of cause with effects that are as sure and unfailing upon those in whom the ideal ego has not been awakened as the law of gravitation itself.

Suggestion is but disguised hypnotism. Suggestion **without the use of hypnotism,** is often malicious, but clothed in the garb of truth it is the dominant force that **rules the life of every human being,** of every nation, of the very world itself.

By its use on the part of the "Mother of Christian Science," thousands of **innocent,** but **honest** and **conscientious,** followers are being robbed of their individuality and selfhood. **By the use of suggestion** on the part of wicked and designing men, the markets are flooded with spurious wares of all kinds and honest money is given for worthless trash. Here is the stronghold of the **patent medicine vendor, the health food manufacturer** and the advertising medical quack, as they play upon the **ignorant credulity** of those who have not learned the intelligent use of their own thought powers.

Through the use of suggestion, people are made to submit on the one hand to many **useless surgical operations,** which often aggravate the functional trouble they were intended to relieve, and on the other hand they are caused to **refuse the help of**

honest surgery for the relief of pathological conditions beyond the reach of any other method of treatment.

There is absolutely **no difference between** hypnotic suggestion and suggestion without hypnotism. It is **the same in kind,** the difference being only one of degree as regards its effects upon **the physical organism.** Suggestion without hypnotism, **even when used unconsciously,** may stealthily and subtly dominate the mind **without the consent** of the individual; **while hypnotic suggestion,** intelligently applied for the relief of functional ills of the physical organism, **is always** employed with the individual's consent.

One cannot be hypnotized without the consent of the true ego—never against his will or without his co-operation. **The true ego is the real man.** It is the intelligent life entity that can control all the mental faculties and use them to vitalize and energize every part of the organism. **When fully awakened and evolved,** the mind and body are its obedient servants. **It is beyond the vision of the microscope** or the range of the dissecting knife, and just in proportion as it is developed will it control the mind, and through the mind produce harmonious and healthful results in the body.

I have no wish to be visionary. Life is too short for impractical theories and suggestions; but to speak plainly, **some of us have been** half-doctors long enough. We have been dealing too much **with effects,** and have failed to consider **an important etiological factor** of disease.

Man is both a **mental and a physical being** and cannot be treated simply as if we were conducting experiments in a **chemical**

laboratory. Heretofore all the advance made in the progress of medical science has been on a physical plane, and the achievements made in the branches of surgery, bacteriology, pathology, and hygiene challenge the admiration and applause of modern civilization. But while bacteriology and pathology can detect, and surgery remove and destroy the diseased part and hygiene lessen the conditions that occasion the infection of the organism with pathogenic germs, the causes of many so-called functional diseases—among them neurasthenia and certain forms of insanity—have remained obscure.

The number of inmates of the insane asylum in every state is yearly increasing far beyond the ratio of increase of population. Why so many diseased bodies and imperfect nervous organizations? These bear a strong evidence of the tendency for the species to degenerate rather than to grow healthier and stronger. These are burning and pertinent facts that are beginning to dawn upon the thinking portion of our craft.

Nor are the people satisfied; all over the world is the spirit of unrest and dissatisfaction being made manifest, as is indicated by the different "mind cure" schools and cults which attempt to carry their claims into extravagant absurdities. The doctors themselves realize this, and just in proportion as they are honest and educated men are they deeply troubled at their own deficiencies.

With a large acquaintance of professional men, I am prepared to say that physicians study hard and work unceasingly, and their brain and muscles and their very heart's blood itself is at the disposal of their patients; but still something more is

needed. Either our remedies are insufficient, or we fail to understand the great human machine upon which we are experimenting.

While we do much good, and earn sufficient gratitude to enable us to strive on, and while we can maintain enough courage to look our patient squarely in the face, the suffering **which we have not been able to relieve** and the relief and cures which we have not effected, and the universal prevalence of **diseases that have not been eradicated** have become such prominent factors in the history of our profession as seriously to humble our pride.

The time has come when psychology should be brought to the front. I would that a chair of physiological psychology were established in all our regular medical schools. I should like to see **every boy and girl** in our common schools, old enough to understand it, made to realize that a power resides in the mind, and how they can use it to maintain a healthy body, and how, by an abuse of this force, they increase their susceptibility to disease from whatever cause.

To say the least of it, the medical profession should better acquaint themselves with the **importance of psychic influences** as etiological factors, as well as equip themselves to make use of this therapeutic power in the cure of disease. When the members of the medical profession become **leaders and teachers** in this important branch, the practice of medicine will be elevated to a higher plane. Then will the breach between that portion of intelligent laymen who feel that physicians are not doing their duty be bridged over.

The **indifference of science** has always been the mainstay of charlatanism. When the intelligent scientific application of

any therapeutic measure is adopted by the medical profession, charlatanism is robbed of its power. **That these people effect cures** of certain forms of functional ills right before our eyes, ills that had not been amenable to cure by our ordinary methods of treatment, is self-evident. **In every city, town and hamlet,** the followers of the different cults and "isms" are gaining in number, and thousands of dollars are reaped by them that should go into the pockets of the medical profession; while on the other hand, thousands of innocent lives are sacrificed on account of the **neglect of scientific medical treatment.**

With the intelligent **recognition** and **application** of suggestive therapeutics **as an aid** in the practice of medicine, conditions and symptoms can be relieved that cannot be reached by any other remedy, and it is cases of this very class that are **going from physicians** and seeking aid from other sources.

The effect of **the mind upon metabolism** is now well established. Emotional conditions of a hopeful, optimistic and cheerful kind, encourage **anabolism** or constructive metamorphosis. On the other hand depressing emotional conditions that conduce to fear and despondency and the like, encourage **catabolism,** or destructive metamorphosis. By suggestion we can produce such **mental impressions** as will increase the **potential energy inherent in the cells** of the organism and thus render them less vulnerable to pathogenic germs and other etiological factors of disease. **This is an effectual means** of conserving energy and increasing the resistive powers of the individual and lessening his susceptibility to disease.

Since the observation of Beaumont upon Alex. St. Martin, the Canadian who had a fistulous opening in the stomach sufficiently large for him to watch the physiological processes of digestion, the effect of certain emotions upon the functions of digestion has been clearly recognized. Beaumont observed **that mental conditions, such as fear and anger,** diminished and sometimes entirely suppressed the secretion of gastric juice by the stomach. At times, under these conditions, the **mucous membrane became red and dry,** and at others it **was pale and moist,** showing the effect of mental impressions upon the vasomotor neuro-regulation of the blood supply to the stomach through the involuntary nervous system. Under the conditions mentioned fluids were immediately absorbed, but food remained undigested for from twenty-four to forty-eight hours.

More recent discoveries by Prof. Elmer Gates, of Washington, D. C., have shown that bad and **unpleasant feelings create harmful chemical products** in the body called catabolins, which are physically injurious. On the other hand, good, pleasant benevolent and cheerful feelings create chemical products called anabolins which are physically helpful.

Quite frequently neurasthenic patients maintain a condition of auto-toxemia on account of **morbid emotional conditions** that dominate their minds, giving rise to headaches, **preventing sleep, conducing to insanity** and proving destructive to all physiological processes. In this class of cases, suggestion **both with or without hypnotism** is our most reliable therapeutic aid.

From the earliest periods in the history of mankind down to the present time, there is **abundant and sufficient proof,** un-

doubted and acknowledged, going to show that in innumerable instances cures of manifold diseases and ills of the physical organism have been wrought by influences brought to bear upon the mind of the person afflicted. You are too familiar with the history of these cases for me to make further mention of them here. **One well demonstrated fact,** the result of honest investigation, is worth a thousand opinions prompted by prejudice. Having witnessed the efficacious application of suggestive therapeutics, both with and without hypnotism, **in hundreds of instances,** I should still feel confident of the inestimable value of this important therapeutic adjunct, if every other physician in the world doubted its efficacy.

You must face the facts as they are: Exact science has proved to us the correctness of the claim of the efficacy of this method of treatment as a therapeutic agent. **The people who make use of it in disguised form are here;** and the proposition that confronts us is, Shall we appropriate the laws that govern the influence of the mind to the intelligent and scientific treatment of disease and make use of them as therapeutic measures, or shall we leave these laws to them?

My observation is that the members of the medical profession are ever ready and anxious to avail themselves of any therapeutic resource that will help to alleviate human suffering. **All that is needed** is a more thorough understanding on the part of the general profession of the theory and efficacy of suggestive therapeutics, and a better understanding of the technique and practical methods of its application.

The idea has been emphasized that only functional and neuropathic conditions are benefited by this treatment. But be it remembered, that a functional disturbance or disease, if neglected long enough, may lead into an organic condition, and that the timely administration of suggestive therapeutics to correct or cure the functional disorder may prevent its resulting in an organic issue.

Furthermore, suggestive therapeutics should be applied with an understanding and comprehension of the anatomical and physiological relations of the organism, as well as of the pathological conditions to be alleviated. It is not to be used to the exclusion of other therapeutic resources, but can always be used with them, for it is not antagonistic to or incompatible with any remedy which helps to cure disease.

It is evident that some physicians are afraid that if they should adopt this method of therapeutics, they would be counted as allies of the quacks and charlatans who misuse these methods. It is the duty of every medical man who is true to his Hippocratic oath, to adopt and use every measure that will help to alleviate human suffering. This science, in the hands of a conscientious physician, is capable of curing diseases, and reaching conditions that no other remedy can reach.

CHAPTER V.

THEORETICAL CONSIDERATIONS.

For our present discussion, let us regard man as being a living, thinking entity; a functioning organism that nourishes himself, breathes, moves, grows and reproduces, adapting himself to his environment, **both acting and reacting** under the influence of innumerable internal and external stimuli.

His body, with its structures, organs and parts, is composed of millions on millions of cells, each one of which, however much it may differ in structure and function from those belonging to other organs and tissues than its own, is a lineal descendant from a single primordial cell. **Just how the mind** of man is related to the brain and nervous system is as yet far from being clear, but we do know that **as the brain is, so is the mind,** and that a healthy, well developed mind corresponds to a healthy, well trained, well developed, and well nourished nervous system.

In the use of such expressions as **soul** and **spirit** in this discussion, it is with the same meaning as **the word mind,** and to suggest that the **mind has emotion, feeling and will,** as well as intellect.

Emotion and will are frequently regarded as spiritual, intellect as mental, and sensation as physical, but they are all **qualities of the same individual mind, soul, or spirit. So in the sense** that I use the term "mind," let it be held to embrace or include

the whole of man's psychic or mental activities, conscious and subconscious, voluntary and involuntary.

Let us think of the human mind as being manifested by or through **the sum total of the functions of every cell** in the body, expressed in thought, feeling, volition, action, motion, perception, conception, memory, etc.

When I say **action and motion,** think not only of objective, conscious, external action and motion, such as feeling, seeing, hearing, reading, talking, walking, etc., **but also of subjective, unconscious, internal action** and motion, including even the action of the lowest cell in the body, in its ability to take in new matter, fix it, change it, and throw it off.

In one sense, each cell seems to have a mind of its own, for it goes on performing its special functions, be it brain cell, or gland, muscle, bone or skin cell. Yet no one of these microscopic organisms is capable of independent existence. **Each has its duty to perform,** but each in turn is dependent, at least in a very large degree, for its own existence upon the activity of other cells of the body, the functioning of which constitutes the complex mechanism of the animal physiology.

Conscious Mind.—Man, as an entity, has conscious psychic or mental activities, which correspond to the functions of the motor area of the brain, the gray matter, the higher centers, the voluntary processes. **The functioning of these** we designate as the conscious mind. These centers respond to stimuli that reach them through the five special senses: sight, hearing, feeling, taste, and smell; and through these **all the lower functions can be**

reached and influenced. Here is the seat of all voluntary action, the home of reason and the higher intellectual faculties.

So far as we know our higher mental functions seem to have their immediate seats in the cortex of the brain and of these mental functions **the anterior frontal lobes** appear to have the power of inhibition. This is as near as we can come to absolute localization of the mental faculties.

Articulation is a motor act and, in common with other motor functions, is governed by groups of cells in Brocars convolutions; but **the mind which is symbolized by language,** giving expression to our thoughts, desires, ideas, aspirations and volitions, **is a phychic phenomenon** dependent upon the entire brain and nervous system. All forms of life that have ideas, however crude they may be, have the power of symbolizing them. **Language is but the symbolization of ideas** and even the lower forms of life have a language of their own, however elementary and primitive they may be.

The failure of memory, as we know, is dependent upon the disolution of the entire nervous system. The latest acquired and consequently the least organized mental attributes disappearing first indicates that **the mind as exhibited by speech,** through the combined effort of feeling, memory, desire and will, is an acquirement dependent upon environment and quality and mode of neuron organization.

Our conscious mind, then, seems to be an outgrowth of education and experience, resulting from the conditions that environ us during our struggle for existence from the cradle to the grave. **This is the mind** that we use in our normal, waking consciousness, as we go in the smooth, even tenor of our ways,

attending to our respective vocations in life, not dominated by fear or anger or emotion, but controlled by reason and will. This, I say, is **the conscious mind** and **represents the higher brain centers in action.**

Hypnotism is the process or method of using suggestion to influence the action of the conscious mind. By suggestion the functions of the motor area of the brain can be soothed, quieted, made still, passive, inactive, at rest, or placed in abeyance. As an individual the subject ceases to use these brain centers and **consents to allow you to use them for him,** and through them to reach and influence the vegetative brain and nervous system, which presides over the physiological processes of the body.

Hypnotism, in one sense, is induced sleep. The only difference between induced sleep and natural sleep is that in natural sleep you are completely oblivious to the outside world, while in induced, or hypnotic, sleep, the subject is, as it were, asleep to every one except the person who induced the sleep. **This is always the result of suggestion.** He is *en rapport* with the operator, in relation with him. He hears and acts upon the operator's suggestions, but appears to pay no attention to anyone else except the person who induced the condition. **This is also the result of suggestion.**

When the conscious mind is rendered passive, as when an individual is hypnotized, then we can better reach and influence all those **psychic activities which lie below the threshold of consciousness,** the study of which throws much light upon the subject at hand.

Subconscious Mind—All those psychic activities which are found below the threshold of consciousness correspond to the functions of all **the involuntary physiological processes**—the functions of the involuntary nervous system, including the functions of the ganglionic and sympathetic nervous systems and the functions of the lowest cell in the body in its ability to **play its part in the game of the life** of the entire physical organism. These functions we designate the subconscious mind.

Moreover, the subconscious mind, which corresponds to the functions of the vegetative brain and nervous system, perceives by intuition; it is the storehouse of subjective memory, and the seat of the emotions. It presides over the functions, conditions, and sensations of the body; over all the vegetative or nutritive processes; over digestion, secretion, excretion, nutrition, waste, respiration, calorification; in short, over all cell life function and development.

When the conscious mind is inhibited or soothed into passivity, as in the hypnotic state, this subconscious mind is amenable to influence by suggestion. **It can be influenced by suggestion without hypnotism,** but in the hypnotic state there is an increased amenability or susceptibility of the subconscious mind to suggestion, and also **an increase in its power to execute an idea** or **suggestion** through its control over the physiological processes of the body.

In the hypnotic state we can influence and make such impressions upon the subconscious mind as will be fully carried out in its influence over the physical organism. And the fact that the subconscious mind does preside over the functions, con-

ditions, and sensations of the body, and is more amenable to suggestion when the conscions mind is inhibited, **gives us in a nutshell** the reason why the results are obtained from hypnotic suggestion or suggestion in the hypnotic state.

How do we prove that the subconscious mind is amenable to suggestion? For upon the truthfulness of this proposition is based the entire structure of the science of suggestive therapeutics.

First, we **use suggestion upon the conscious mind.** This we do when we hypnotize a man, as was demonstrated in a previous chapter. Then, by suggestion in the hypnotic state we can **better reach and influence** the deeper thresholds of consciousness.

After an individual is hypnotized, you will remember that we held up his arm and suggested to him that when we counted three that arm would be stiff and that he could not take it down. We challenged him, "You can't take it down." The arm remained stiff, showing **that voluntary function** was here influenced or inhibited by suggestion; that the **conscious mind** which presided over this motor function was amenable to our suggestion.

Then it was suggested that after the **medicine had been applied to his arm** it would be dead and would have no feeling in it; and a pin was thrust into his arm **without the slightest evidence of pain,** showing that the subconscious mind, which presides over the sensations of the body, was also amenable to suggestion.

Then that both the conscious and subconscious minds were amenable to suggestion, was proved by suggesting to him that when he stood up and we counted three, he would be stiff, so

stiff that we could lay him across two chairs and he would not bend. We then caused him so sustain the weight of **from two to four hundred pounds** without the slightest inconvenience.

A further demonstration that the subconscious mind presides over sensation and is amenable to suggestion was given when we suggested to the individual **that his lip was dead** and had no feeling in it, and a pin was thrust through his lip, not only without the slightest evidence of pain, **but without producing bleeding.**

So we see that the mind of man, both conscious and subconscious, both voluntary and involuntary, is amenable to suggestion, and that suggestion to the voluntary waking consciousness is as much hypnotism as is suggestion in that increased condition of suggestibility usually referred to as the hypnotic state; that any influence brought to bear upon the mind of any individual by any means whatsoever is hypnotism; that the individual is hypnotized by suggestion, and that an individual with his eyes wide open, thinking he is in possession of all his conscious faculties, is frequently as much amenable to suggestion as is the subject in that sleeplike condition usually referred to as the hypnotic state.

The conscious mind presides over the voluntary functions; it corresponds to the functions of the gray matter, the motor area of the brain, the higher intellectual faculties; but in the presence of a stronger personality, be it an attorney at law, a minister, a teacher, a salesman or physician, **it is amenable to influence** and controlled by suggestion.

The hypnotic state, when induced by the method that we employ with the medicine, is always induced with the consent of the voluntary waking consciousness. We always get the **consent and co-operation of the will** of the individual to be hypnotized; but by suggestion without a sleeplike condition, as is used by all classes of individuals, the conscious mind may **be stealthily and subtly dominated.** Hypnotic suggestion, however employed by the medicine method which we have demonstrated and described, is always used with the individual's consent.

The subconscious mind presides not only over the involuntary functions, but over all cell life function and development. I have frequently **produced copious emesis** by suggesting to an individual that he had taken ipecac, thus showing the effect of suggestion upon the involuntary physiological processes. In a number of instances I have had physicians accomplish this result in my class work by suggestions made by them **to the subject that they had hypnotized.**

I say by suggestion we **can influence cell life.** In not less than one hundred instances have I taken a hatpin from a lady's hat and **without sterilization** thrust it through a large fold of the cheek of a person without the slightest ill results following. **In several hundred instances** have I thrust a smaller pin without sterilization through the face or an arm of an individual without the least untoward results.

We certainly cannot influence the bacteria upon the pin; then we must increase the resistive power of the cells in the face in some way. Whether it is done by encouraging leucocytosis or the migration of phagocytes, or whether we increase the resis-

tive power of protoplasm direct, has never been explained. **Theorize upon that proposition as you will;** its meaning has a far deeper import than appears at first upon the surface. To me it indicates that we can increase the resistive power, life, strength and energy, **of every cell in the body** by suggestion, both with and without hypnotism; so that in the fight between the etiological factors of disease, which is ever being made by the cells of the body, we can help these cells in their struggle against pathogenic germs or other etiological factors of disease.

Physiologists have ever endowed the brain centers with a peculiar form of energy of their own, indefinitely referred to by such expressions as **neuric energy, nerve force,** and the like. These higher centers occupy a relation to the general cells comprising the physical body similar to that occupied by a dynamo to a piece of machinery. By suggestion we can **convert potential energy into dynamic energy,** latent energy into moving energy, and in this way increase the resistive power of every cell in the body.

I am aware that some physicians will shrug their shoulders and raise their hands to heaven in protest against the foregoing statement. It goes against the grain to present an idea so completely at variance with their preconceived opinions. But **if they will reflect and verify,** they will be forced to bow down before the evidence of facts.

I do not mean to say that an instrument previously **infected with a culture of** *anthrax bacilli* can be thrust with impunity into the flesh of a hypnotized subject, neither do I mean to give license for any failure to observe the strictest rules of asepsis,

which has been the means of the brilliant achievements that have crowned the efforts of modern surgery; **but let the facts in the case speak for themselves.** Let us hew close to the line of truth, let the chips fall where they may.

I have in **at least five hundred instances** taken a pin that has not been previously sterilized and thrust it through a fold of the skin in the face or arm and with **but one single exception** have never observed **the least unpleasant results.** Even the exception in this case only goes to prove the efficacy and power of suggestion in the accomplishment or support of the position that I have taken.

In one instance I used a **small blade of my pocket knife** and jabbed it under a fold of the skin for an inch without soreness resulting. **The antiseptic property of the blood** is not to be discredited in making allowance for the result, nor elimination by bleeding, but in this case the arm bled only a few drops. **On an average** where a pin was used, the arm did not bleed one time in fifty. Nor do I forget the **natural resistive power** of the cells themselves in a healthy individual, and this, in my opinion, can by suggestion **be strengthened** to **a wonderful extent.**

The one exception where the arm became sore **was in the case of a physician** for whom I gave a treatment by hypnotic suggestion and relieved him of a **tinnitus aurium of twelve years' standing.** He was an extremely neurotic individual and when I awoke him after the treatment for his tinnitus and asked if anything had hurt him in the least, he replied, "No."

"**Did you know** that I had thrust a pin into the flesh of your arm?"

"No, you did not or I should have felt it," said he.

"Do you feel it now?" I asked. "No, not in the least," said he. "You did not stick me really, did you?"

"Yes," I replied, "And here it is now," and I pushed back his cuff and let him see the pin yet through the fold of the skin.

"Take that out," said he, in a most excited manner.

His tinnitus was relieved, and after one year when I last heard from him, had not returned. Yet he seemed hurt with me that I, a physician, should have taken such a risk as to thrust an unclean instrument in his flesh.

In the afternoon he had a **red, painful arm,** with a general temperature of 103° F. and he asked that I hypnotize him again and get rid of that condition! I hypnotized him and gave him appropriate suggestions to relieve his pain, quiet his nervousness, and give him a good night's sleep. After awakening him, I assured him that his temperature was **due to malaria.** He took twenty-five grains of quinine that evening and was all right the next morning.

This, I say, was **the only case** that I have ever experienced where there was the slightest unpleasant symptom after sticking a pin without sterilization into the flesh, and I am quite sure that I have made that experiment **not less than five hundred times.**

It has been reported that a physician jabbed a dull lead pencil into the flesh of a hypnotized subject and produced an infection. Such a procedure would destroy the cells in that part and is **not at all a parallel case** to where a sharp instrument is used and proper suggestions given to influence the result.

These facts have led me to conclude that through the influences exerted by the higher centers of the brain, over the vasomotor neuro-regulation of the blood supply to the part, increased leucocytosis results, and that the theory of phagocytic resistance, as advanced by Metchnikoff, is an important and constant factor in natural immunity. According to this author, leucocytes having arrived at the spot where the intruders are found, seize them after the manner of the amoeba and with their bodies subject them to intracellular digestion.

The facts mentioned in regard to the case of the physician, whose auto-suggestions were adverse and most unfavorable, as against at least five hundred cases where suggestions were given in the hypnotic state that would possibly favor this natural physiological process of immunity, lead me to conclude that cell activity is increased or retarded in even a local area by suggestion. We know that every cell in the body through the complex mechanism of animal physiology is influenced by centers of activity in the brain. These centers can be stimulated and encouraged into action by suggestion. We can convert potential energy into dynamic energy, latent energy into moving energy, and in this way all the physiological processes can be increased or encouraged, and by suggestion both with and without hypnotism, we can aid the cells of the body in the fight against the etiological factors of disease, whether due to pathogenic germs or other causes.

The physician, then, in the light of such indisputable facts is a factor either for good or harm in the sick room. How often is it the case that his training in the pathological laboratory so

fills him subconsciously with **fear** of pathogenic germs that it completely offsets his confidence in the **natural resistive powers of his patient;** like a dog frightened and cowed, he goes into the fight with a drooped head and his tail tucked in, exercising a most depressing influence upon his patient, rather than with a sufficient faith in the **potentialities inherent in the living cells** that comprise the physical organism, to encourage them into action!

Has it not often been your experience to see a patient very sick, so that from the pathological condition there existing, reason would cause you to doubt the possibility of his recovery? But he had **faith in you,** expected to get well, was hopeful and optimistic, and that encouraged you both to encourage him and to do your best for him. Later on, when he was safely on the road to recovery, when he was thanking you for what you had done for him, you gratefully reminded him that he was getting well on account of his **courage and bravery,** and that had it not been for his will power and determination he never would have recovered. You really felt that **your services played a small part** in his recovery.

On the other hand, you have had patients who were not at all seriously sick, so far as their **apparent pathological conditions** would indicate, yet from the very first visit you realized that you had failed to get *en rapport* with them. You realized that you "did not make good", and upon your return the next morning you found that he was nervous and had not slept well that night; there was an increase in pulse rate, his respirations were quickened, and he was over anxious about himself,

and from this condition he continued to go on from bad to worse until, finally, upon your last visit, when you realized that he would not recover, chagrined, humiliated and mortified you could not but feel that he had **failed to recover on account of the morbid mental attitude** taken towards his condition in its incipiency. He died for the lack of the will to get well.

The experience of hundreds and hundreds of physicians coincides with the cases just cited. Why is it that the mental attitude of an individual plays such an important part either toward recovery or non-recovery? For this reason: Everybody's subconscious mind is constantly amenable to the influence, suggestion, and control by his conscious mind, and when you fully comprehend this proposition, you see very plainly that every one is treating himself by self-suggestion all the time, whether he realizes it or not. Your own thoughts, your own beliefs, your own predominating mental characteristics, whether you will it or not, whether you believe it or not, whether you know it or not, are the suggestions that are ever influencing your subconscious mind either for good or harm.

So much so is that true, that you can put it down as a safe proposition that the individual who is hopeful, optimistic, and cheerful, constantly looking on the bright side of life, carrying sunshine and cheer into the lives of others—that such an individual by his mental attitude conduces to the health and strength and well being of his own physical organism as well.

On the other hand, the individual who is pessimistic, despondent, and blue, having morbid fears about his own physical condition, worrying over the affairs of life, unduly emotional,

pining and complaining; such an individual, by his mental attitude has a wrecking, weakening, ruinous effect, not only upon his own physical organization, but upon that of others.

As we pointed out in a previous chapter, emotional conditions of a hopeful, optimistic, and cheerful kind encourage anabolism, or constructive metamorphosis, a building up of the cells of the body; while depressing emotional conditions, worry, fear, envy, anger, jealousy and such like, encourage catabolism, or destructive metamorphosis, a tearing down of the cells of the body.

In the study of **the etiology of neurasthenia** and allied conditions, including all functional disturbances—and their name is legion—**self-suggestion** enters into these cases **as a causative factor** that is of a far deeper import than is generally recognized; and in treating this class of cases, as well as for the nervous element of any disease, acute or chronic, surgical or otherwise, it is our duty as physicians to make such impressions upon the conscious minds of our patients in our daily association with them as would indirectly influence the subconscious mind, **through autosuggestion.** At least we must make the patient feel that we understand his case; that we are especially interested in him; that we are giving him due consideration, and as far as possible we should hold out a strong belief or expectancy that he will get well. Just in proportion as we keep him cheerful, hopeful, and optimistic, **just so far shall we help him on the road to recovery.**

Think of these two minds as two sets of men upon a war vessel. **The men upon the upper deck** give their attention to the fleet over yonder. They give their attention to the objective world. These are performing the function of the conscious mind.

The men below deck give their attention to the **internal machinery of the ship,** paying no attention whatever to the outside world. They represent the subconscious mind. Their respective duties are entirely separate and independent, yet the men below stand ever ready to obey the dictates or orders or signals from the men above.

Every human being is giving orders that will encourage the performance of every organic function every minute and hour of his life; or he is giving orders that will inhibit, retard, and weaken the involuntary psychic activities or nervous functions. So you see that suggestion is used both with and without hypnotism, and that any influence brought to bear **upon the conscious mind** of your patient indirectly reaches his subconscious mind. We are using it every day of our lives for the good or harm of ourselves and for the good or harm of our patients.

To show you the influence of the mind upon the bodily functions, I will cite one illustration. I was once talking to a physician about hypnotism or suggestion when **a band stopped in front of his office** and began to play. In a jocular way he remarked, "I should like to see you hypnotize that band and stop them from playing." "All right," said I, "come and watch the procedure." **I procured three lemons** and gave a half of each to as many little boys on the street, instructing them to walk round and round the band, **sucking the lemons and making faces** at the musicians. The result was such an increase in the secretion of their salivary glands that the men were compelled to stop and swallow or empty their instruments of saliva. They were **unable to continue** their music and the little boys were put to flight.

An individual with **a large "bay window"** is usually a man who gives full appreciation to the thought of the dinner hour, the breakfast hour, the lunch hour. This pleasurable anticipation of the approaching meal time encourages the free flow of blood to his gastric mucous membrane, with a result that he has a plentiful supply of gastric juice, a good appetite, a good digestion and a healthy physique.

On the other hand, **our cadaverous looking brother** usually approaches his meal hours with pessimistic forebodings and goes to his home at meal time more as a matter of duty than otherwise; thus he unfortunately fails to encourage this passive organ sufficiently to enable it to secrete sufficient gastric juice to give him an appetite or to secure a perfectly digested meal.

By suggestion we **can influence man's conscious and subconscious psychic activities** and thus every organ and every cell in the body can be stimulated. **The daily visit of the physician** to his patient is one of the most important therapeutic factors at his command through the very influence of his own personality.

Before going into the practical application of the theories of hypnotic or therapeutic suggestion, I desire briefly to call your attention to other phases of this subject, which, though they may not appear to you perfectly scientific, have a bearing upon the subject at hand of such importance that it cannot be ignored.

We remarked in the outset that the subconscious mind perceived by intuition, that it was the storehouse of memory, the seat of the emotions, and presided over the functions, conditions, and sensations of the body. So far, we have been elaborating the influence of the subconscious mind over the functions, con-

ditions, and sensations of the body, having made it clear that when the conscious mind was inhibited, the subconscious mind was more amenable or susceptible to suggestion, and that suggestions given in the hypnotic state were more effective and lasting in certain selected cases than suggestions without hypnotism. We also made it plain that the conscious mind of every individual was amenable to influence by suggestion, and that any influence brought to bear upon the mind of an individual by any means whatsoever, came under the broad domain of suggestive therapeutics.

The Subconscious Mind Perceives by Intuition.—It is now considered that thought transference, or telepathy, is rendered possible on account of the ability of the subconscious mind of one individual to be impressed or influenced by another mind by some means apart from the generally recognized modes of communication. It may be that this is based on sympathy existing between two persons concerned and deals with something in which they are mutually interested. Be that as it may, that there should be such a relation between two individuals of congenial habits of thought and action seems to me to be no more unreasonable than that two mechanical instruments delicately and harmoniously attuned the one to the other should receive electrical vibrations through air and earth and water thousands of miles apart by which our wonderful system of wireless telegraphy has been perfected.

In connection with this phase of the subject I am at present an agnostic, but I am ever ready to stand by facts as I find them, hoping that some day, perhaps not far distant, some of the

problems that have so perplexed honest investigators on this line will be explained by the discovery and control of a **natural law** that has been in operation forever and, like all other natural laws, only required the intelligence of man to appropriate and use it for his welfare and happiness.

I have had some **demonstrations** and **observations** of certain phases of this subject presented to me which have led me to certain conclusions that I desire to bring to your attention, without which it would be impossible intelligently to practise suggestive therapeutics.

I once **took a young man** whom I had frequently hypnotized, and, while in the hypnotic state, blindfolded him. I wrote upon a piece of paper the following suggestion: "Go to the mantelpiece and get the baby's photograph and bring it to me." My wife, who was also present at the time, read the suggestion. **Not a word was spoken** more than to tell him that, when I counted "three," I wanted him to go and do what was written upon the piece of paper; that I would not indicate what I wished him to do by look or gesture or word, but would constantly think of it.

I then removed the blindfold, told him to open his eyes and do what was ordered on the piece of paper. He at once went to the mantelpiece, put his hand upon the first photograph nearest to him, which was the wrong one, but put that down; then to another which he also put down; then to another which he also put down; and lastly he took the Baby's photograph indicated, held it in his hand and turned around with a blank expression on his face and handed it to me. "Good," said I. "Be seated and sleep on."

At this juncture my wife threw a **winter coat over his face** and I wrote on another piece of paper, that he would go to a washstand, thrust his hand in the water pitcher, and wash his hands, which he did. I again wrote on another piece of paper that he would take a stool upon the floor and turn it bottom side upwards and take a seat in the bottom. This being done, I wrote that he would go to a lounge in the room, lie flat down upon his face, cover his head up with a pillow, and go to sleep.

Take notice that all these suggestions were written, not one word being spoken. Each suggestion was carried out precisely as written upon the piece of paper. When I awoke him and asked what he had been doing, he replied "Nothing." When I told him what he had done **he denied it.** When I presented the written suggestions and assured him positively that he had carried out every suggestion given in writing, and that not a word had been spoken to indicate what we wanted him to do, **he laughed aloud** and said that we had played a great joke upon him.

Since that one demonstration I have never doubted that man has a means of conveying an idea or impression to another individual which lies outside the domain of the five special senses. It is by this that thought transference or telepathy is made possible. **As to whether the reader believes** in thought transference or telepathy or not, is a matter for him to decide. It is recognized as a fact by some of our ablest scientists and psychologists of the present day. It affords an explanation of a **great mass of unexplained phenomena** that have been hitherto relegated to the realm of mysticism. If there be any truth in it, it has its practical bearing upon our subject at hand in this

way. The more faith one has in his ability to hypnotize a subject or to use suggestion both with and without hypnotism, the greater will be his success. The more faith we have in any therapeutic measure the better will be the results from its administration. The more faith we have in that inherent quality of resistive power within our patient, call it by whatever name we please, the better are the chances of our patient to recover.

The physicians who have the most confidence in suggestive therapeutics always secure the best results in its application. A doubtful mental suggestion may outweigh a positive oral suggestion, if it be possible to give a positive suggestion orally when one is in doubt, and a physician may fail to get results for the lack of confidence in the procedure.

Furthermore, we, as physicians, should cultivate a spirit of optimism and self-confidence in our demeanor with our patients. The physician who goes into the sick room with an air of self-sufficiency, which is based upon professional qualifications and an understanding of human nature, will always inspire his patients with confidence and secure that mental attitude on the part of the patient that is desirable. Such a man usually possesses tact sufficient, not only to influence the mental attitude of his patient in regard to his own condition, but to drop a suggestion here and there upon the minds of those around him which will secure the proper psychological environment under which the best results may be obtained.

Many men succeed in the practice of medicine far beyond their professional qualifications, because they possess tact and

self confidence sufficient properly to impress and inspire confidence in those with whom they associate.

On the other hand, we often see a well qualified physician fail to succeed, on account of his lack of ability to carry that suggestive influence which is so essential to the personality of the successful physician. **A lack of faith in self,** however much one may try to conceal the fact from observation, repels that confidence that others would have in one.

I am frequently asked how to acquire confidence in our ability to succeed in accomplishing what we have undertaken in life, and I usually answer: **"By going the route; by making the fight, by hard work, concentration and study, and the acquirement of self-confidence which can only come through knowledge and experience."** That indefinable quality of personality called "personal magnetism" is comprehended here. The man who goes down the stream of life day after day **self reliant,** optimistic and cheerful, with a pleasant greeting for his friends, glad that everything is as well with him today as it is, glad of the privilege **to work** and **to study** and **to learn** and **to be of use in the world,** is always the one that is looking out for a better tomorrow, and unconsciously attracts to him the elements that go to make up success in life.

With the physician this is indicated by **his library, his post-graduate diplomas, his office equipment,** and the interest that he takes not only in his profession, but in all questions that contribute to the welfare, happiness, and onward development of the human race. **The world has no use for human inertness.** We must keep in line with the progress of our age, or step aside.

The individual who is pessimistic, despondent, and gloomy, and so **morbidly self-conscious of his own life's battles** that he has no time to speak to his friends, who is continually speaking disparagingly of life and its opportunities, brooding over his own troubles, whining and complaining, will drive away those elements that go to make life worth while.

This intuitive faculty of the subconscious mind often forces itself upon the recognition of the physician in his routine work. You have frequently called to see a patient who was not properly within your clientele. You perhaps wondered why you received this call. On returning the next day to make your second visit the minute you entered the sick room you could tell whether your patient **was better or worse, and who** among the environment was for you or against you, and you have at times observed that the patient would be progressing very satisfactorily but for the **antagonistic suggestive influence** of some influential member of the family or friend who favored the patronage of another physician.

Properly to get *en rapport* with all those who collectively go to make up the environmental influence brought to bear upon your patient constitutes tact, and is one of the greatest elements of success in the practice of medicine.

The Subconscious Mind is the Storehouse of Memory.—Memory seems but to be the impress made by previous experiences in life upon the entire brain and nervous system. Aside from conscious objective memory **every experience in your life** has left its indellible impress upon your subconscious mind. This

is what gives rise to a great many **subjective impressions and sensations** which haunt the lives of neurotic individuals.

All education and instruction and experience of any kind is retained by the subconscious mind. These ideas or impressions here lie dormant until ready to be brought out by the association of ideas. You would say that some of your best prescriptions have been extemporaneously devised upon the spur of the moment; but the **skilled surgeon finds every previous experience** in the dissecting and operating room and pathological laboratory instinctively forcing itself upon the domain of consciousness as an impelling guidance or impulse to every step of the procedure.

By suggestion in the hypnotic state we **can obliterate old impressions and memories** which are the result of unpleasant experiences in life and plant new impressions and ideas that will influence the future life and conduct of an individual both consciously and unconsciously.

The physician who has the happy faculty of getting the confidence of his patients and keeping them feeling good is always a successful therapist. **At every visit** he lifts his patient out of a morbid self-consciousness of despondency and gloom and impresses him with his own strength, optimism, and cheerfulness. Dignity and self-poise should at all times be maintained to obtain the best results.

That the subconscious mind is the store house of memory explains why you can give a patient a **suggestion in the hypnotic state at nine o'clock** this morning that will give him a good night's sleep, beginning at a specified time, the **following evening**

and **every night afterward.** I have frequently broken up nervous, wakeful habits of neurotic individuals in a single treatment by suggestion in the hypnotic state.

The nervous element of an acute disease may be aggravated or a neurasthenic condition maintained on account of some morbid emotional condition resulting from an unpleasant experience in the previous life of the individual, rendering the patient nervous, preventing sleep, and proving destructive to all physiological processes.

By the use of hypnotic suggestion we **can modify the sense impressions causing these** depressing emotional disturbances; give such people more plentiful and refreshing sleep, and plant upon the subconscious mind such impressions as will make them more hopeful, more optimistic, more cheerful, and happier in many ways, resulting in a good appetite, good digestion, improved nutrition, and a complete restoration to health. **By suggestions properly given** in the hypnotic state we can change the individual's point of view in regard to experiences which upset the mental and nervous equilibrium. I cite one case for example:

I once had a patient, a lady, who had a son **accidentally killed.** She was of an emotional nature, neurasthenic, and rather inclined to be on the hysterical order. Three hours after the accident which caused her son's death I was called. The large bed-room was full of friends who had come to express their sympathy. These people had **unconsciously used suggestion** to make her feel worse. Her minister had been on the scene to express his sympathy, and unconsciously used suggestion to make her **more self-conscious of her bereavement.**

As I walked in the door I began to ask each of those present to leave me alone with my patient. By the time I had reached the bed, the room was cleared of all present except her husband. I attempted bravely to talk her into being quiet, but my very presence seemed to have been a signal for an outburst of this emotional condition. **At every attempt to reason** with her or to soothe and console her, she would cry vehemently and answer, "Oh, you don't know, you don't know."

Seeing that I was making no headway, I prescribed chloral-hydrate, 15 grains, and potassium bromide, 30 grains, to each dose, four doses, repeated every two hours. I directed that no company be allowed to come into the room and instructed her husband to sit by her bedside and place a cold towel upon her forehead, changing it every ten minutes. This was in August and the weather was extremely warm.

After the fourth dose of the prescription just mentioned had been taken, I prescribed 15 grains of trional to the dose to be given every two hours for four doses. Three hours after the last dose of this was taken I administered a **hypodermic injection** of morphine sulphate, one fourth of a grain, with hyoscyne hydrobromide, 1/100th.

Three hours afterward she had still been unable to sleep, was very nervous, had a terrific headache, and I felt that it would be unsafe to administer more medicine. **At that juncture I hypnotized her.** The medicine previously given apparently had a cumulative effect as she was very easily hypnotized.

I then suggested that she **would sleep soundly all night;** that her sleep would be quiet and refreshing; that while she slept a perfect spirit of **resignation** would come over her and she would wake in the morning feeling perfectly resigned to the accident and bereavement; that she would sleep soundly until eight o'clock the next morning, at which time her husband should awaken her, by placing his hand upon her forehead and commanding her to wake up; that she would be **feeling perfectly resigned** to the accident, and would eat her breakfast and give her attention to her domestic relations and feel proud that she had ever been permitted to be the mother of so worthy a son.

On my return the next morning I found that she had slept soundly all night, and she at once began to tell me that she had decided—giving me the very ideas that I had suggested to her the night previous.

I feel quite sure that a greater change in her mental and nervous condition had taken place during this one night's sleep, together with the influence of the suggestions given, than would have resulted under normal conditions after a period of several months had elapsed.

I am furthermore convinced that **there is much insanity, the etiology of which is obscure,** where, in many cases, if the timely administration of hypnotic suggestion had been used to give those people good sound sleep, to change their mental attitude toward the conditions that were worrying them, to **make new impressions upon their cerebral cells and substitute more wholesome mental states,** a large proportion of these cases could have

been prevented, upon the principle that an ounce of prevention is worth a pound of cure.

The proof that all insanity is dependent upon diseased states of the brain has never yet been rendered in its entirety. **Organic pathological changes** are found in paresis, senile dementia, alcoholism, and probably in epilepsy, dementia praecox and climacteric insanity and this leaves out of consideration the condition of a large proportion of those adjudged as insane. **The correlation between mental symptoms and pathological anatomy** is as yet largely to be determined, at least in a considerable part of the acknowledged field of insanity.

Many people are incapable of thinking and reasoning for themselves, as the result of false training, education and environment. **You can give them advice** and make all the appeal to reason within your power, and yet they seem **unable to execute your ideas.** The physician who has that spirit of altruism sufficient to enable him to appropriate these methods can here apply hypnotic suggestion and obtain results that cannot be obtained in any other way. **He gets control of his patient** and **puts him in control of himself.** He educates the individual in the art of controlling and directing **his conscious** and **subconscious psychic** or **mental activities.**

There are others upon whom the **cares of life** have borne heavily, whose involuntary nervous system has received many a hard blow; it has been shocked and wrought upon by cruel impressions or experiences which take possession of a patient and torment his life. **These are found among all classes,** from the highest bred college graduate to the most ignorant working class.

They have not yet learned to control these involuntary impressions. By suggestion in the hypnotic state you plant within them a new consciousness, a consciousness that is power.

When they are sick there is no time for re-educating and re-training them. Like miners buried in a deep, dark hole in the earth, where huge piles of shale and debris had caved in upon them, they need help. Like a man in jail, they want to get out. **They expect you to do something for them.** To give them narcotics and sedatives but temporarily benumbs their psychic activities, interferes with all functional processes, weakens their powers of resistance, interferes with elimination, and is **actually destructive** and **weakening** to both mind and body. The judicious, intelligent application of suggestion, both with and without hypnotism, in this class of cases, is a boon to these unfortunate sufferers who rely upon us for help.

The Subconscious Mind Is the Seat of the Emotions.—**Whatever impulse** dominates the individual—whether fear, worry or anxiety, envy, anger, jealousy, love or the purely animal passions—makes its appeal to and impress on the subconscious mind, which corresponds to the functions of the involuntary nervous system.

We all have noticed that the functions of the different organs of the body are greatly disturbed through emotional influences; sorrow brings tears to the eyes; prolonged grief interferes with the secretion of gastric juice by the stomach. Of all emotional conditions which are most detrimental, however, **fear, which is the opposite emotion to self-reliance** and self-confidence, is the worst. Fear is the **natural accompaniment** of **weakness,**

ignorance and disease. Fear has a wonderful inhibitory influence upon both the motor and voluntary, as well as the involuntary, functions of the body. Fear of sickness, fear of death, fear of failure—fear of anything of any kind, of any nature—is detrimental to all physiological processes. We invite what we fear. **Fear weakens our resistive powers to disease.** It is the frequent experience of physicians to have pneumonia and enteric fever patients who die of fear and not on account of the pathological condition existing. This has been observed by physicians everywhere.

In the **Century** for December, 1899, R. R. Bowker gives the following translation of an Arabic legend:

The Spirit of the Plague entered the gate.
One watching, asked, "How many wilt thou slay?"
"A thousand," spake the Spirit, "is my quest."
The Plague made end. The Spirit left the gate.
The watcher cried, "Ten thousand didst thou slay!"
"Nay, one," the Spirit said, "Fear killed the rest."

At the very onset of illness the patient **becomes afraid,** gets nervous, does not sleep, and manifests a lack of confidence in the ability of his physician and doubts his own ability to recover. **He thus has a psycho-neurotic condition** complicating his disease. His resistive powers are thus lessened, all physiological processes are disturbed, and death results from fear and not on account of the pathological condition, which would run its course and go on to recovery but for the psycho-neurotic element.

We should distinguish here **between conscious and subconscious fear.** Tuberculous patients are noted for their ap-

parent optimism, hopefulness and cheerfulness, which is frequently only on the surface. Yet as a result of this very optimism, as has been observed by all physicians, even in the presence of **such a gross pathological condition,** the resistive powers of many tuberculous patients are augmented to an astonishing degree. We frequently see others, however, who are so **subconsciously dominated by fear** that all involuntary nervous functions are disturbed, on account of impressions gathered from experiences which have come to them through their own observation of the disastrous consequences of this disease. **In this class of cases** suggestion, both with and without hypnotism, is particularly beneficial. We quiet an irritable, involuntary nervous system; we get them to **breathe deeper;** we give them suggestions which produce **more plentiful** and **refreshing sleep** and plant subconscious impressions which result in the re-establishment of **the normal functions of every healthy cell** in the body as far as this is possible. The result is an **increase in the patient's resistive powers,** a conservation of his protoplasmic energy, and he is in condition more successfully to combat the pathogenic germs which are making their ravages upon him. **The etiological factors of disease,** whether due to pathogenic germs or other causes, **are powerless** in the presence of cells of an organism with **a degree of resistive power** sufficient to render them invulnerable.

All that contributes to the health of an individual in the way of nourishment, medicine, climatic conditions, exercise, etc. of course should be appropriated.

The etiological factors of disease are here, and they are here to stay, in spite of our modern methods of disinfection and im-

proved sanitary conditions, which have practically abolished yellow fever, small pox, cholera, and other diseases regarded as inevitable curses of the human race.

We as physicians have studied the dead body too much and the **living organism not enough.** We have underrated the self-healing processes of Nature, and the physical effects of psychologic influences. This has frequently given charlatans who make use of these methods in disguised form, an opportunity to give us a black eye. We are now, however, giving more attention than ever before to **social and mental and hygienic causes** of health and disease and are placing the practice of medicine upon a more rational basis. We are giving more attention to **the prevention of disease:** and to methods of maintaining the health of the individual.

Suggestion is used both **upon the conscious and subconscious mind,** and whatever we do in the way of teaching our patients how to keep well by **conforming** to the **conditions under which health can be maintained,** comes within the broad domain of suggestive therapeutics. It is the purpose of suggestive therapeutics to help our patients to help themselves by better control and direction of their conscious and subconscious psychic activities.

It is important to remember that the subconscious mind of every individual is **amenable to the influence,** control, or suggestion of his own conscious mind. His own thoughts, his beliefs, his predominating mental characteristics, **as the result of education and environment,** are the suggestions by which he is continually influencing his subconscious mind.

So much so is this true, that we judge character by the expression of the faces of people that we see every day. **The strong face** and the weak face, the honest face and the villainous face; the face which indicates a high order of individuality and self-reliance, selfishness or servitude, all are in evidence. **The fact is,** the body is a perfectly negative element, existing according to the laws of heredity, environment and education. **Thought is a great factor** of change and growth, and thought means that brain cells are functioning **in response to internal and external stimuli. The will power** is a positive part which can guide and regulate our thinking, **provided it has once been evolved** sufficiently to set up a new line of mental reaction, **through memory and experience.** We are all using our thought forces or self-suggestions, then, as either creative or destructive agencies, in accordance with this natural, physiological law.

In order to think for one's self, however, the individual must be equipped. He must have a well trained and well developed mind and nervous system which can come only by conforming to the laws of health and by familiarity with the facts that are demonstrated by science, and not through the influence of the modern metaphysical theories of the present time, which act as temporary narcotics, lulling the intellectual faculties into passivity. **Yet, to cultivate habits of cheerfulness,** optimism and self-reliance conduce to health and strength of the physical organism, on account of the influences of such mental states upon the involuntary physiological processes. **Such states of consciousness** as give rise to pessimism, despondency, jealousy, anger, worry, envy and discontent, exert a wrecking, weakening, ruin-

ous effect upon all the involuntary functions. The system becomes loaded with **metabolic toxines,** which in turn render the individual more miserable and morbidly self-conscious.

People frequently say they are miserable on account of their physical condition, and they are, but they are often **reaping in full measure** the conclusion of their own mental action. The mind governs both the conscious and subconscious actions of the human body. **The condition of the body** is largely the result of what an individual has thought and believed, and thought and belief are **determined by his education and other experiences in life.** The influence of education upon the expression of the face and physique has been observed by us all and furnishes a fitting illustration of the influence of the mind over the body.

CHAPTER VI.

OTHER PHASES OF PERSONALITY.

The tendency of the logical mind of today is toward the acceptance of a philosophy that seeks for unity of body, mind and spirit. These are qualities of the individual, but, scientifically speaking, they are one and the same thing. Thus, **monistic philosophy,** or monism, recognizes that mind, spirit and matter, soul and body, God and the world, are abstractions and not things in themselves, but are incomprehensibly bound together in their inseparable oneness. **Call this philosophy** "Monism" or "Monotheism," to suit yourself, but you cannot get away from the stupendous fact, even though our half-trained understandings and narrow experiences are unprepared to comprehend it, that the whole universe **is animated by a single principle of life,** and mode of energy, and that such expressions as **body, mind,** and **spirit** are **qualities** of this one principle, thing or substance. But since it is impossible to think of any **quality** or thing except **by comparison with something else,** each one of these qualities should be held in equal appreciation.

Knowledge is but an apprehension of facts based on **a representation** or description of those facts in terms that can be comprehended by human intelligence.

So, then, in our analysis of the qualities of personality, we can with consistency, in the light of these premises, say that each individual **becomes self-conscious** of his existence upon

one of three planes respectively, physical, mental or intellectual, and moral or spiritual, **all qualities** of the same individual.

For instance, **the atom of hydrogen gas,** considered for so long a time to be the smallest subdivision of material substance, is now known to be itself composed of from twelve hundred to three thousand **"ions," or charges of electricity,** or elemental units of force; and it is now recognized that there is in the universe but this one element. Every other element or combination of elements is composed of **this one elementary substance** coming together in different degrees of density. So that the space a thousand feet above our heads is composed of precisely the **same elementary substance** as is the earth beneath our feet.

Furthermore, **the cosmos,** with its countless planetary systems and planets, some of which are millions of times larger than this little earth upon which we live, together with the spaces between them, is all composed of **this one elementary substance, call it physical, mental or spiritual, as you please.**

The only logical conclusion, then, is that **the entire cosmos is an organism,** pulsating, throbbing, vibrating, living, in which we live, and move and have our existence.

And as is the cosmos, so is man. He is an organism, pulsating, vibrating, living. **And as is man, so is each individual cell** in his body with inherent potentialities and powers that are constantly being manifested, functioning in its own way, as it plays its part in the game of life **according to heredity and environment.**

Yet life is a fact, and all forms of life from the first *unicellular moneron* down through the millions and millions of years

in which the evolutionary development of man has passed, are all sharers of that one ever-present life, with numberless varieties of expression, infinite and limitless.

In the **evolutionary development** of the human race and of the human intellect and character, each individual seems to become **self-conscious of life** upon one or the other of these three respective planes before mentioned, **physical, intellectual,** and **moral or spiritual,** each of which is the result of training, **education** and **environment,** so far as their manifestations **in his life are concerned.**

Heredity plays an all-important part in the growth and development of body, mind, and character. So much so, that a single fertilized cell contains **all the psychic qualities,** dispositions and traits of personality, physically, mentally and morally, of ancestors for ages past. **All the potentialities are transmitted** in this microscopic, fertilized cell.

The great majority of people are **conscious of life** only upon the **physical plane.** They have scarcely any higher conception of existence and its meaning, other than what appeals to the appetites, eating, drinking, and sensual indulgences. Like two-legged animals they live in many instances upon a plane **even lower than the brute,** as is indicated by expression of face, physique, **character of speech, habits and conduct.**

Others there are who **in self-consciousness reach** the next higher plane and seem to go no further. There are people that we all know, concerning whom, though they may have an intellectuality so cold and pulseless that it glitters as the stars, and be strong enough mentally to make wonderful achievements in

the fields of politics and commerce, etc., it is nevertheless easy to discover that there is an **element in their personality** that is lacking. It is lacking in expression of face, in handshake, in tone and quality of voice and speech, and especially in their conduct and demeanor with their fellow man. In the presence of such an individual one feels more as if one were face to face with **a stone or an iceberg,** rather than in the presence of a human being.

As to what conscious existence upon the higher plane of selfhood indicated implies, it is hard to define, yet it consists in the evolving and developing of **those higher elements of human character** regarded as the ethical and aesthetic and moral sense. **We see it manifested** in its influence upon human life in magnanimity, generosity, altruism, kindness, bravery, and all other **distinctly human faculties.** It is the higher functioning of **the true ego,** the real man, call it **body, mind, spirit, life or soul.** It is manifested in man or woman by the exhibition of those inner qualities **of moral and spiritual dignity,** in the determination to do only **that which is conceived** to be good and right, **not** in the outer esteem of their fellows or in the **worthless praise of a conventional society,** but in their own inner consciousness. "Unfortunately," says Ernest Haeckel, "we have to admit that in this respect we are still largely ruled by the foolish views of a lower civilization, if not of crude barbarians."

This animating life principle that functions in human beings defies analysis, evades our comprehension, and transports our thoughts beyond what is finite and terrestrial. **But it is in man** because man is, and if it were not, he would not be. Haec-

kel says, "Why trouble about this enigmatical 'thing in itself' when we have no means of investigating it?"

This unexplained, undefined and **incomprehensible** element in man is **the real ego.** It is consciousness of life itself. **It is the power** that manifests itself on the physical, mental, or spiritual plane, in its voluntary human expression according to **knowledge, education** and **environment.** It is the **intelligent life entity** which, when fully awakened and evolved in the consciousness of the individual, makes him strong, independent, capable and free.

To discover this element of selfhood is to **discover the real self.** It is to find yourself out.

It is the privilege and duty of every individual to manifest the highest expression and meaning of life upon each of these planes, **physical, mental** and **moral;** to develop harmoniously **as an athlete,** in body, mind and character.

When this highest element of selfhood is evolved in self-consciousness, then **do mind and body** become man's obedient servants. Then do we discover the meaning of Emerson's expression, that "Every man is a divinity in disguise, a God acting a fool."

Strange talk this may appear to be giving to medical men, but it is the most essential truth in connection with our subject.

In the application of suggestive therapeutics we must regard man as a **thing of life, of force, of intelligence, of will and reason,** that emanates from, and is a part of, the central source of all life, with millions and millions of cells in his organism that are

ready to respond to stimuli in the form of human personality, therapeutically the **personality of the physician.**

In all events in the light of this monistic philosophy that is accepted by **every prominent man of science** at the present time, let us as physicians recognize that this inherent potentiality or quality or element **is latent in every human being,** whether recognized by him or not, and let us make use of this animating life principle in therapeutics, using it as **one of Nature's forces** by conforming to the law that governs it.

The intimate relation between **neuron structure and mental activity** is now fully appreciated by both physiologists and psychologists. We are taught that the morphological structure of nerve elements bears a most important and intimate relation to mental activity. That the mode of neuron structure is regarded as mirroring the mode of organization of the psychic life.

But it must also be remembered that every psychical phenomenon has its physical concomitant; which is but to say that every mental state has its influence upon the body. The changes which appear in neuron structure are, then, **the result of education** and **experience** which promotes its growth and development. **Faculty proceeds function.** Inherent in every human organism are latent faculties or potentialities which can be developed through the influence of **environment and education—other names for suggestion.**

Step by step it is dawning upon us that **humanity is an organism** and that "the satisfaction and requirement and functioning life activity are impossible without social co-operation,

and it is only then that the individual becomes **freed from the bonds of blood relationship."** "In other words," say Sidis and Goodhart, "with the growth and development of social organization, **organic bondage** is replaced by functional relationship."

The lives of human beings are thus so interrelated that personality is but the outgrowth of experience. The life of each individual is constantly influencing the growth and development **of brain** and **mind** and **character** of other individuals by whom **he is also** influenced.

Morality, the functioning of the highest element or quality of selfhood, conforms to the law of evolution, and like organic evolution, **this psychic evolution** is but the adaptation of individuals to conditions of existence. The law of psychic evolution, as of evolution in general, is **from structure to function,** from **bondage to freedom** of the individual elements.

In the light of the foregoing pages, then, you, reader, are a being, **body, mind** or **spirit,** animated by the one principle of life from which you come, **in common with all human beings** and all forms of life. You have a mind and a body such as you have made it for yourself, modified, of course, by the **laws of heredity and environment. You physically** are the obedient servant, or should be, to the controlling force or life entity within. Your face and physique have been formed, shaped and moulded, by your **use or abuse** of this inherent life force within you.

This inherent life force, question of all questions, what is that? Who are you? In the light of modern knowledge of **the cosmic process of evolution** we are constrained to answer that

you are a part of the universal source of all life, which you see manifested wherever you see anything, from the dead earth upon which you walk, to the eyes of those that you love, flowers, trees, clouds, moon, sun and stars, even the stars so far away that a ray of light, going at the rate of one hundred and ninety-five thousand miles per second, beginning at the time that it was formerly believed that the world was thrown out into space by special creation, could not have yet reached this planet, infinite and limitless. It is referred to by scientists as "force." Herbert Spencer says, "The eternal energy behind and within all things." The idealists or religionists say, "The God in whom we live, move and have our being."

Think of this power, of which you are, how it converts bread and meat, fruit and vegetables into bone and muscle, brain and blood, and how you are endowed with, or have evolved, will and reason and other faculties of mind and character, and then dare to exercise these inherent potentialities as a co-worker with infinity. Divine molecules are we with the privilege to think, reason, will, and do for ourselves.

It is utterly impossible to hypnotize anyone without getting the consent and co-operation of the self-conscious ego—unless it be one in whom this self-conscious ego has not been evolved. See how we get the consent and cooperation of this, the real man, when an individual consents to relax, close his eyes, with lips slightly apart, to secure thorough relaxation, as if to say, "All right, doctor, mind and body submit I unto you, I step aside, the door is open."

At this juncture and while your patient is in this condition, by your better educated and better equipped personality you pour some of **your own psychic life** in the form of suggestion, **into his.** You thus renew and stimulate latent, dormant, psychic activities, encourage the functions of his body, and you **put life and health** and **strength** where there was weakness, **in conformity with a natural law.**

It is estimated that the normal individual has from **eight hundred million** to thirteen hundred million cells of gray matter in his brain and that the average individual uses but **about one-tenth** of this entire number. By the influence of personality upon personality, then, we convert latent energy into moving energy, **potential energy into dynamic energy,** and thus stimulate and encourage the functions of every cell in the human body.

Every time you come into the presence of a patient, it is your privilege and duty to get the consent and co-operation of **the ego, that highest element of the self-conscious individual,** and appeal to this higher psychic quality, **the man himself,** the organized, intelligent life entity, that has simply thrown this physical cloak around him, and encourage it to vitalize and energize all life processes **upon the physical plane.**

We, as physicians, have studied dead eyes that do not see, dead tongues that do not talk, dead ears that do not hear. We all know that the **mind, soul,** or **spirit,** or **life,** name it as you choose, is the real man, and yet this ever present entity has been an unconsidered element in our consideration of human beings.

I am aware of the sneers that occasionally come from a few individuals who disregard this quality of human personality.

They are usually those in which **this higher self-consciousness** has not been evolved. They have not discovered themselves; we stand upon different planes and they deserve our pity.

There are other individuals who are so hide-bound in religious orthodoxy that they are themselves hypnotized by creed or dominated by the power of suggestion until they are not open to the consideration of this subject in its broader aspects. **There is no phase of philosophy** or religious theory or question or problem of life, educational, ethical, moral or political that a conscientious truth seeker is not likely to jar in the discussion of this subject. **They are under the sway of precedent** and prejudice, and it seems to them a species of disloyalty to question the hoary old beliefs which have become as much a matter of family inheritance to them as the color of the eyes or hair or shape of the features.

But times and manners change. Skepticism is the natural fruit of growing intelligence and increasing experience. It is simply the **unwillingness of the truth seeker** to be satisfied with anything less than the truth.

The great majority of mankind are practically untouched by the progress of present day knowledge. The tremendous task of teaching men and women to think for themselves and learn the great lesson of **self-reliance** has scarcely begun. All but our most intelligent people are creatures of a school of thought or belong to some intellectual herd. **Never was there a time** that so demanded fearless, independent, tolerant, logical thinking.

Reason is mankind's greatest, highest and noblest faculty, and as such should be the supreme court of the mind, and all other impulses that flitter and dance and play in the stream of human consciousness, either intellectual or emotional in character, should be subject to its rulings.

Will, the executor of reason and judgment, should be loyal enough to follow their dictates. It is upon this condition only that sanity is maintained. **Will and reason,** however, are in keeping with the law of evolution, **psychic qualities** that are developed by **education, knowledge** and **experience.**

Consciousness, the most fundamental faculty of the human soul, is a stream of endless psychic states, resulting from previous experiences, incessantly changing as the restless, white capped tides of ocean, that can exist only by virtue of its endless unceasing motion; and this **continuous change is what makes conscious life.**

Conscious life itself, then, is a stream of varying psychical states, which quickly follow one another in perpetual motion, rolling, rising and sinking, ebbing and flowing, with never an instant of rest. **The elementary psychic states** which lie below consciousness constitute the subconscious realm. Here is a great ocean of memories, sensations, imaginations, emotions and impulses, desires and aspirations, hopes and ambitions, fears and disappointments, successes and failures, which are **past impressions or memory pictures** that linger in the human brain. **These rise to the realm of consciousness** and are interpreted in thoughts and feelings from which there is no escaping, and these thoughts or feelings in turn constitute mental states

which exert an influence upon **all involuntary physiological processes.**

The power of attention fixes the mind on such ideas and sensations or memory pictures as are most worth while to the individual, and **by constant assertion and iteration,** reasoning and persuasion, suggesting and impressing, we substitute such impressions as will bring the individual **under their influence,** both consciously and subconsciously.

By suggestion we can drive back these subconscious impressions or memory pictures, and if we but have personality and self-hood to dare to make an **appeal to the highest element of character** within those of our patients who need thus arousing, we have rendered the greatest service that one human being can possibly render a fellow man. **Arouse the higher intellectual faculties,** the higher brain centers, and the highest moral ideal into action, and you truly put life into your patient.

In every great battle that has been fought in both ancient and modern times, brave leadership by a strong appeal made through patriotism and pride has so **aroused the psychic element** in soldiers in battle that men have been frequently known to stand and fight through heat and cold, day and night, with hunger and thirst, for days and days at a time and conquer by **unwavering will and determination.** They have thus exhibited a degree of resistive power in many notable instances that has been **beyond human conception.** In all instances in battle the soldiers on the **victorious side easily recover** from serious wounds and mutilations, while, on the other hand, those upon the side that is defeated, die of mere trivial inflictions.

In all heroic achievements of men, reserve, **subconscious power,** has been brought into action, stimulated or evoked by the conditions of the moment, that enables individuals to accomplish which seemed absolutely impossible in proportion to their recognized capacity.

These are facts that every observing individual has frequently recognized and that are **acknowledged by us all.** If human beings have within them that **psychic element** which can be evoked under extraordinary conditions to so increase the normal resistive powers and capabilities of both mind and body, why should we as physicians not in a sense, **be generals or leaders** in our association with our patients, and in our daily relations with them **evoke latent energy** and heighten their normal resistive powers to the ravages of any disease, acute or chronic, organic or "psycho-neuro-pathic."

The successful men in every profession, in all trades and departments of life, are enthusiasts, whether it be a Martin Luther, a Savonarola, a Bismarck, a Napoleon, a Joe Wheeler, or a physician. Men have in innumerable instances been known to **stir their fellow men to action.** The simple country maiden, Joan of Arc, by her enthusiasm and unwavering self-confidence, headed the French army **in the face of defeat** and led her stalwart troops to victory.

What are we as the medical profession doing as leaders for the people? As guardians of the public health are we doing all within our power in the way of teaching people how to keep well and healthy and strong, without relying upon us to admin-

ister to their **physical necessities** or upon priest or clergy to control their **psychic activities?**

In directing an individual how to control his or her psychic activities and **steer them into channels of useful thought and conduct,** the entire man, physical and psychical, body and mind, or soul and spirit, if you choose, must be taken into consideration. **Body, mind, and spirit** must be considered as qualities of the individual, one and inseparable; their inter-dependence must be recognized.

At this time, when those possessing abnormal powers of imagination, with unlimited emotion and little reasoning, are being led by every absurd theory and metaphysical dogma that is presented under the pretense of an especially commissioned divine guidance, we should be prepared to rise to the occasion and acquit ourselves as men in the highest sense. The great need of the world today is **education, knowledge and guidance,** other names for honest, conscientious, truthful suggestion.

The problems of health are the problems of life, problems of education and economic considerations which involve the questions of **work, food, clothing, homes,** and all other essentials that make for human happiness. **Manhood is only in the making.** We are yet evolving, growing and developing. The process of evolution is as active today as it was a million years ago, and **it points to the evolution of the mind as well as the body, of the God in man, and not the triumphant brute.** All those who in any way by ideas, provision of means, or achievement contribute to the evolution of the human race, are the world's true benefactors.

Life consists in the free exercise of our faculties and happiness in the successful performance of duty and achievement. "The law of natural selection" and "The survival of the fittest" will go on forever.

The self-conscious ego can and does function on the **physical plane,** making a tyrant or a beast of man; or on **the mental** or **intellectual plane,** making him capable of reasoning and thinking for himself; or on the **ethical or moral plane,** making him a reasonable, useful human being, dependent on **education and environment. The optimism of scientific minds** consists in the belief that upon these three planes of life mankind must be strong, capable, and free, and that we shall not dwindle into **physical weaklings, intellectual nonentities,** or **spiritual slaves** or fanatics.

The fight made by the medical profession **against parasitic germs** in the fields of pathology, surgery, medicine, and hygiene, has been crowded with glorious achievement, but a **greater work** is still before us. Our battle is only half begun.

Since the days of Vesalius, Harvey and Jenner, down to the present time, every step of advance made by medical science has been boldly contested and fought by ignorance, fanaticism and misdirected zeal. **The warfare of science** must go on forever. Nature has surrendered to science her most valued treasures. We have subdued steam and electricity, harnessed the waterfalls, tunnelled the mountains, rendered the bosom of the ocean amenable to the great service of mankind, and demanded from the bowels of the earth her most sacred treasures.

Those who regard humanity as a finished product, now standing at the mercy of an anthropo-morphic deity, are in the truest

sense retarding the evolution, growth, and development of the **highest psychic qualities** of man and womanhood.

Science has no fight to make against **true religion**; its struggle is with ignorance and intolerant dogmatism. She demands a religion that **appeals to the brain as well as to the emotions**; to **reason** and **not to ignorance,** one that will develop the entire individual to the fullness of perfect manhood and womanhood. Life is a struggle. Every idea that seeks to be embodied demands a conflict. In order to live, we must dare to be, to declare our own individuality.

Physicians have done much for the protection of the human body, but what are they doing to prevent the **parasitic infection of absurd beliefs and dogmas** and theories that at the present time infect the human mind with their **blighting, weakening influence** upon the development of body, mind and character?

Science and everyday experience agree that Nature cares nothing for individuals. What the people of our time need is plain living, clear thinking, and right action, to develop potentialities of both mind and body.

The psychical correlation of religious emotion and the sexual instincts is such that any sect that starts with extravagant sentiments of love to all men will fascinate and take hold of an easily impressible type of unscientific and unthinking people. Yet minds that have been stored with nothing more substantial than historical fiction and **agitated so long by unreasonable dogmas** of a capricious deity from which they naturally shrink, are easily captured and held in subjection by any mind-soothing

theory under the guise of religion that has a romantic or mystical flavor. **A lack of contact with the world** and an unfamiliarity with the facts of science have left these credulous people with no more powers of reflection than a child, and they naturally have, in consequence, abnormally deveolped imaginations and emotions, and are easily captured by absurd and illogical metaphysical vagaries.

In my travels among the physicians I have talked with **many men of scientific attainments,** and in the ranks of both the clergy and the medical profession they deplore the fact that theologians of the present day have been so slow to accept and utilize the message of science, and that so many have lacked the moral stamina to shake off the worn out and useless doctrines of an ignorant and superstitious age; **yet among the clergy** are many who teach and preach better than their creed. They have **no fight to make against science,** but look upon science as the handmaiden of true religion. **The majority, however,** have been held in the coils of creed and fettered by dogma and thus coerced into a beaten path at the sacrifice of reason and judgment. **The more enlightened clergymen** realize this, and just in proportion as they are educated and scientific men, are they boldly getting away from the absurd dogmas and shaking off useless external formalities that have fettered the aspiring spirit, progress and growth of humanity so long.

In their slowness to interpret life and its meaning in the light of present day knowledge, no wonder that we see an article in one of our leading periodicals headed "Is the Pulpit a Coward's Castle?" **And yet there was never** in the world's history a

greater need for strong, fearless, unblemished and unfettered men willing to devote their lives to the help of their fellow men.

Do you ask what this discussion has to do with suggestive therapeutics? It has at the present day a most important bearing. The present status of this subject is so related to those influences **of an educational nature** that furnish food stuffs to the minds of the people, that I should feel that I had dodged the issue, **the most important issue,** did I not boldly face these problems, which I know are agitating the minds of scientific medical men everywhere, and give them the consideration that they so pre-eminently deserve.

Religious beliefs and **health and disease** stand in precisely the same relation as does mind and body. It is simply a question of those influences that dominate and control an individual's **psychic life.** To do another's thinking for him is to regulate his actions and control his life. It is a question of the factors that are **obscuring** and **obstructing** the **path** of social and intellectual progress in opposition to those influences that elevate thought and action among living men and women.

No intelligent physician would think of overlooking the question of dietetics in the treatment of a case of chronic indigestion, especially when unwholesome food was largely responsible for this physical malady. **It is of equal importance,** if not more important, to take into consideration those elements that are harmful or healthful in the growth and development and stability and maintenance of mind and character. **The physician who ignores the psychic element** in the consideration of sickness and disease is as one-sided as the Christian Scientists

who refuse to recognize the needs of the body. The consideration of the maintenance of the health of an individual involves those factors that **maintain and sustain health and strength of both mind and body.**

How many thousands of people have died before men found out which were poisons and which were foods? **To teach by killing that others may learn** to use their faculties has been the method of the cosmic process in the evolution and development of the human being. **Even today the greater part of sickness** and disease is but Nature's protest against human beings for violating her laws, physical, hygienic, dietetic, psychical, etc. In the consideration of those factors that contribute to human health and happiness, all these elements must be considered.

Every step taken by the scientific men of the medical profession to abolish cholera, smallpox, and yellow fever, has been opposed by mystics and sentimentalists. But though thousands of lives have been saved by improved sanitation, hygiene, dietetics, disinfection and asepsis in the physical realm, there is a field of **no less importance in the psychological realm** that needs to be fumigated, disinfected, drained and cleared of parasites that live and thrive upon the ignorance and superstition of weakness and innocence. Modern science is turning the **great searchlight of truth** into every dark corner where these poisonous microbes may be found lurking.

The universal acceptance of the doctrine of evolution by all the important non-sectarian universities in our country and by **the more enlightened theological schools** has sounded the death knell of the old formulated creeds and dogmas based upon

the ideas of special creation that has fettered the aspiring spirit of humanity so long. **To say that you believe in the doctrine of evolution** is but to say that you believe in God's way of doing things, and of all classes of people who ought to be ready to accept this important truth and give the people the benefit of the light it sheds upon human life and conduct, the men of the learned professions should be the first.

Fear, an emotion which is the result of an analysis of consequences, has been so instilled in the human mind by the teachers and preachers of anthropo-morphic theism, until the great masses of people who are not sufficiently educated to think for themselves, have been unconsciously dominated and development of body, mind and character suppressed.

The revelations made by scientific investigators do not take God out of the world, but render us more intimately self-conscious of his all pervading presence. Moreover, they only add new luster to the matchless character whose simple teaching of faith, hope and love has for two thousand years stirred the noblest impulses of the human soul, and proved to be the greatest factor in the evolution of the ethical and moral element of the human race, in spite of the war and bloodshed and destruction of human lives that have been perpetrated by **religious sects pretending to be his followers.**

The great need of the world today is men to interpret life **in the light of present day knowledge** and to tell the people the truth as the more enlightened individuals see it, and who will not falter and be cowardly on account of the ignorance and superstition of ages past and gone that is still exercising its de-

moralizing influence upon our present civilization. **All the modern creeds and cults, "ists" and "isms"** of the present day are but an evidence of the recoil of the people from the dogmatism and intolerance of medicine and theology.

With the present conception and theory of the origin and destiny of man, the individual has made a wonderful discovery. He has learned that he is **no longer a serf,** but that he, too, has creative power, and he dares to give it manifest expression in his life and conduct. **With this changed mental attitude** toward the universe and its process of development, he has been made self-conscious of the God in his own soul, and life has a zest and meaning which is equivalent to having put him into a new world. It has altered his conception of himself and his relation to all forms of life, and he realizes as never before his **intimate relation and responsibility and duty to his fellow man.** He no longer considers himself **a stranger and an exile in a foreign country,** but **here** and **now** he is at home, securely abiding in the great, living, throbbing, pulsating heart of Nature. **Side by side with his fellow man** is he permitted to work and in his own way to contribute his best efforts to the furtherance of human happiness.

No class of human beings have done so much for their brethren as the members of the medical profession. In dens of poverty, fields of pestilence, or amid the heat of shot and shell in war, they are ever conspicuous for their presence. **Day and night, through heat and cold,** sunshine or rain, they are found anywhere, from the lowest brothels to gilded palaces, in laboratories and hospitals, amid contagious diseases or with the in-

sane, laboring to promote the comfort, health and happiness of their fellows.

Ignorant mankind has been **so long preached the worm of the dust** theory and been taught to call himself weak, humble, powerless and worthless, until many have become so on account of their own thinking. **Let them once get a glimpse** of their divine origin, in the light of modern evolutionary knowledge, and dare to exercise their faculties and inherent capabilities of body and mind on lines of useful endeavor, **and seek health by conforming to the conditions of health,** and dare to claim and exercise the ability **to think, will, reason, and do for themselves,** and many there are in this world who, like Pygmalion's statue Galatea, will be transformed into beings of life.

We are beginning to look at ourselves with new eyes. The old religions, which condemn the body as vile and sinful and advocate a locality of everlasting punishment, are passing away. We now realize **that the mind helps the body** as much as the body helps the mind, that mind, body and spirit **are qualities of the one individual** and that within every human being lies the power through intelligent living, acting and thinking, to develop both mind and body into a high degree of perfection.

The human will, **guided by reason,** is the positive part of our mental equipment and the body is the negative, responsive to its rulings and dictates. **Intelligent, logical thinking** as the result of education and experience, effort and determination, are **the great factors of growth** and the most powerful forces in the universe. It is force itself in its voluntary human expres-

sion. **By these all other forces** of Nature are controlled and utilized for the happiness of man.

We have nothing to fear from the modern unlicensed systems of healing which have arisen out of the development of a better appreciation of **the psychic qualities of man** within the past twenty years. **The fittest will survive.** As among Ruskin's Lilies, the sunflowers and weeds shoot up their heads in gorgeous array and they are only giving expression to a single phase of truth. The universe is big enough to furnish a stage of action for us all, so let them do their little stunts in peace.

The coming physician, however, must of necessity be a broad-gauged and well educated man. His therapeutic armamentarium and mental equipment will be such as to enable him to avail himself of all methods of treatment, physical, mental, social, moral, ethical, that make for the health and happiness of his patient.

A large percentage of the people who are sick, ailing or complaining do not need medicine or surgery. What many of them really need, though they may not be cognizant of their need, is direction and advice, knowledge and guidance, all suggestive measures that enable them to conform to the conditions by which the wonderful recuperative powers inherent in the biological elements of the organism can have a chance to re-establish health. **Human beings are so constituted** that they cannot in this infantile stage of their development, stand alone. The great organism of **humanity must have men strong, capable, self-reliant and well educated,** to direct and influence the functions of the great mass of the people, just as the higher centers of the brain influence all the lower bodily functions.

The hunger of the body for bread and fruit, meat and vegetables, is no more real than the hunger of the human intellect for facts and principles by which life and conduct may be guided.

The charlatanism of the past twenty years has an important message for the medical profession, as it has also for theologians. In hundreds and thousands of instances have they demonstrated to us that there **are mental and physical causes of diseases,** on the one hand, and that diseases of the physical organism, not too far advanced, can be benefitted, ameliorated and oftentimes cured, by **correcting these perverted mental conditions** on the other.

Science has pointed out and discovered the mental toxemia that has been disseminated and scattered broadcast unconsciously and unintentionally by the halting, timeworn, moth-eaten and useless **systems of education and ecclesiasticism,** and there are thousands and thousands of individuals who need help, in the way of aid to enable them to do rational, intelligent thinking and living.

What is disease? I believe that even Virchow would agree that it is a condition wherein the **cells of the part affected** do not properly perform their functions. At first it begins as a mere so-called functional disturbance, which, though the aid of the microscope be required to detect it, **always implies a physical change.** At least, there is a lessened degree of resistive power in the cells of the organism. In this weakened condition the individual cells are more vulnerable and are unqualified to put up a strong fight against their enemies. **Now an exciting cause**

of disease comes along in the form of a pathogenic germ or other etiological factor. In the case of the bacteriological infection a fight ensues. Brave and altruistic little men as they are, the phagocytes throw their bodies into the combat to destroy the pathogenic enemy by intracellular digestion, or if, forsooth, they fail in this, they pile their bodies by the thousands and millions, to build, as it were, an impenetrable breastwork for the protection of the remaining cells of the organism, each one anxious and willing to sacrifice his own life that his fellows may be protected. Thus an organic or structural change takes place and this may then be beyond the pale of psychological methods of treatment.

But in conjunction with surgical, medicinal and other therapeutic measures, we can, by psychological methods, aid in the re-establishment of every other bodily function which may have been disturbed on account of this local, organic, or pathological condition; and so we not only help the individual in a general way, but we indirectly aid in the healing processes of surgical procedures and supplement medicinal and other therapeutic devices. We quiet nervousness, relieve pain and promote sleep. The result is better appetite, increased digestion and assimilation, improved nutrition, and a consequent conservation of energy throughout the entire physical organism.

So, then, it must appear to the logical mind, that there is no class of cases, acute or chronic, surgical or otherwise, in which the psychological factor does not play an important part in conjunction with all other methods of therapeutics.

CHAPTER VII.

SUGGESTION APPLIED WITHOUT HYPNOTISM.

It is in functional and **neuropathic conditions** that suggestive therapeutics is most applicable, yet it must be remembered that a functional disturbance weakens the resistive power of the cells of the organsim and invites bacteriological invasion, and that the speedy and timely correction of the functional disorder may prevent its resulting in an organic lesion.

There is an important psychic element in all classes of diseases and conditions, surgical, infectious, febrile, or otherwise. Physicians on the coasts, where yellow fever until only a few years ago wrought great destruction of life, quite frequently reminded me of what an important role mental influences played in helping or hindering a patient suffering with this disease.

One physician recited a case in which he had under his care a young man sick with yellow fever, whom he had led to believe himself suffering only from malarial fever, in order to avoid the harmful influence of fear of yellow fever in his case. His family had acquiesced in this scheme and the young man was doing well and no apprehensions were entertained as to his recovery, until a thoughtless friend of the patient who had himself recovered but two weeks before from yellow fever was admitted to see him. **He made it dawn on the consciousness of the sufferer** that he had yellow fever instead of malarial fever, a severe illness instead of a trivial one, and thus so wrought upon his emotional or involuntary nervous system by the fear that he had

planted by his unwise suggestions that the patient at once took a change for the worse. "His stomach and bowels and kindeys literally went to pieces," and he was dead in two hours after the young man's visit.

A physician of my acquaintance related the following case: His wife, who was supposed to have reached full term of pregnancy, was taken ill with a unilateral lobar pneumonia with temperature of 104, pulse 120, the first day. **Two days afterward** she was delivered, and on the fourth day after the onset of the pneumonia and the second day after parturition, at about nine o'clock at night after using the vaginal douche, hot poultices to the chest, and ice to her head, she went to sleep with her hand gently clasped between both of his own.

He likewise dropped off to sleep, when after perhaps two hours had elapsed, she awoke startled with a muttering delirious groan which awoke him. Her pulse was 160 a minute and the tempearture was afterward observed to be 105.5 F. He quickly prepared a hypodermic injection of strychnine sulphate 1-20 grain, and just as he had pushed the water to the end of his needle to exclude all air, he looked down as if to say, "Give me your arm."

Her condition was such **before she went to sleep** two hours previously, he had entertained very great apprehensions of her ability to recover, and now he felt decidedly uneasy about her, though he made every effort to conceal his forebodings. **As her eyes met his** he felt what she afterwards admitted, she was about to say, namely, that she was going to die or that she was dying. **Quickly getting possession of himself** he spoke to her loudly and

strongly, positively asserting, "You will be better in a moment. I have seen a hundred people more sick than you are get well. Give me your arm." As he looked at her again, having withdrawn the needle, a smile was on her face and tears trickling down both her cheeks. Putting his face close to hers and gently caressing the other cheek, he suggested, "You were only dreaming; let me renew the poultice and ice bag and show you how good you will be feeling in a few moments." At once a new consciousness took possession of her, the anxious expression was gone, her pulse was slower and her voice decidedly stronger. That proved to be the turning point in her recovery, though the lung did not begin to clear up until the eighth day.

There are, in the experience of every general practitioner, in certain individual cases, crises where the psychic factor has decided the recovery or non-recovery of his patient. Had the case just related have been surrounded by an emotional, overanxious family, who would only have aggravated that peculiar psychic condition, that physician's wife would probably have been dead inside of two hours.

The author has had in his own experience several incidents where he has been called into consultation to see individuals who were seriously ill, where the entire family had confidence in his judgment, which also made the patient more amenable to his suggestions, and where the attending physician had practically read the patient's death warrant by giving an unfavorable prognosis in no uncertain terms, and after making an examination, he has begun psychic treatment by the positive statement to the patient, "You are going to get well all right."

In one such case that happened to be turned over to me after a brief absence, where the physician in temporary charge had given a positive, unfavorable prognosis, I assured the patient in the presence of the physician at my first visit that **he was going to get well,** that the treatment that he was on was precisely the right one, that a decided change for the better would take place that very night. **The physician,** a very dear friend of mine, followed me out of the room, and in a subdued tone, addressing me by name, said, "I hate to see you fall so hard. There is no more possibility of that patient getting well than there is of your taking wings and flying."

The case in question was that of an old man seventy-eight years of age, who had been sick for ten days with la grippe and who now had an acute lobar pneumonia. The prognosis given by the physician in this case was just such as ninety-nine physicians out of a hundred, who did not fully recognize the value **of the psychic factor in therapeutics,** would have given in such a case.

"Why do you say that he will not get well?" I asked.

"It is my opinion, based upon the pathological conditions, together with his age and continued illness," was his reply.

"But my opinion is that he will get well," said I.

"Yes, but you are not doing right to **make him believe** that he is going to get well when he is so sick," said he most kindly.

"But, doctor, that is just what is going to make him get well; because **I can make him believe it,** will strengthen the bridge that is to tide him over to recovery."

After that I assumed control of the situation and allowed no one to enter that room who **did not believe** that that patient was going to recover on account of confidence sufficient in me to rely upon my judgment. **Even the physician agreed** to cooperate with my plan out of respect for my wishes in that particular case.

When he returned the next day, he said to me in the consulting room with his face lighted with a smile, "He is really better. Your presence has greatly benefited him."

It was eleven days before that lung cleared up, his temperature went down and heart beats became strong and natural for his condition, **but he recovered.**

The point that I wished to bring out has been illustrated in this case. The physician who does not fully **appreciate the psychological factor** in therapeutics is far more likely to give an unfavorable prognosis—and in many instances he might as well knock his patient on the head with a sledge hammer as use psychic influences, unconsciously though it be, **to retard rather than promote recovery.**

It is frequently the case that the physician comes into the presence of a serious pathological condition, so depressed himself by his knowledge of pathology, that he forgets to put confidence in the recuperative powers of his patient, which can be encouraged and stimulated to increase all physiological processes. **This unconscious suggestive influence** may so plant fear in the patient, accumulating with double force on account of the depressing **environmental psychologic influence** which fol-

lows as a logical sequence, that it can be stated as a scientific truth that the prognosis frequently kills the patient.

People die frequently under such conditions of purely nervous shock. **Shock** may be defined as being a **complete suspension of some** and **partial suspension of others of the functions of the nervous system.**

Fear alone, an emotion which is the result of the analysis of consequences, exercises an inhibitory influence over all the nervous functions, **both voluntary and involuntary.** Every idea that originates in the conscious mind as the result of self-analysis of subjective sensations, symptoms, and conditions, reproduces itself in the body.

Physiologists have always endowed the nerve and brain centers with a peculiar energy of their own, indefinitley expressed under such terms as neuric energy, nerve force, vis medicatrix naturae, etc. At any rate **these higher centers** stand in a similar relation to the body to that in which a dynamo stands to a great building full of intricate and complex machinery. When properly manipulated **the influx of energy** goes to every organ, cell and function of the body, **giving stored up energy** to the special functions as occasion requires..

The mental attitude of the patient to his own condition is the determining factor in the utilization of stored up reserve psychic power. **The very belief** on the part of the patient in the possible serious outcome of his illness, even when he is, as far as it is possible for a human being to be, apparently devoid of fear, disturbs and depresses him and weakens all power of resistance.

An illustration of the influence of the conscious mind upon

voluntary functions is well demonstrated by concentrating the mind upon the arm held at right angles to the body and constantly iterating the suggestion that "the arm is getting stronger and stronger."

It is usually supposed that a man cannot hold up his arm for more than five or ten minutes at a time. I once took a class of ten young ladies bewteen twenty-two and thirty years of age, and by suggestion each one was enabled to hold her arm at right angles to her body for one hour. During this experiment I held my own arm at right angles and standing in front of a circle that had been formed, I requested that each one of the young ladies look at the bridge of my nose glasses and positively assured them that as long as the eyes did not lose sight of this object, their arms would remain strong.

"Mine is tired and I cannot hold out much longer," said one, after about fifteen minutes.

"Then let me touch the point of your elbow and it will be strong again," I quickly replied. Then going from one to the other who requested it, I kept that sort of thing up until the hour was up.

Each one of the young ladies thought that I had given them the strength to hold their arms out so long. In a sense I had done so, by suggestions to their subconscious selves, though they were wide awake and in no sense hypnotized, as the term is ordinarily employed; yet in reality there was as much hypnotism exerted as if they had been in a state of active somnambulism.

I have frequently taken a group of children, who have always been favorite associates of mine, and began with them in what

I was pleased to call "exercises." I would first begin by having all hold out one arm in a prize contest which they enjoyed immensely. **For four out of six** to hold out an arm at right angles to the body for an hour and a half after the third or fourth day's exercises, was nothing unusual.

They could also stand on one foot for more than an hour, still at times and hopping about at other times with the other foot in hand, either in front of or behind them. At any rate, I held their attention and **constantly kept up a suggestive influence** by addressing my suggestion to one and then another, expressing my confidence in his or her ability to hold up an arm or stand on one foot all day long.

In my demonstrations and lectures given to physicians, I always have had one or more physicians present take a suggestion, without the slightest attempt to induce sleep, by agreeing to co-operate with me so that I could show him how he could convey a suggestion to his own subconscious mind and get results that would surprise him. **In over five hundred instances** have I placed physicians submitting to this experiment across two chairs and jumped upon their bodies with my entire weight of two hundred pounds, and in nine-tenths of the instances they would say that I had apparently placed no more than three or four pounds upon them. **They were astonished** and frequently incredulous when I informed them that they had sustained my weight.

Anyone who believes that he can do so, can easily lie with head in one chair and heels in another and hold up one hundred and fifty or two hundred pounds. On the other hand I have

frequently witnessed a physician attempt this where **he did not believe it possible** for a man to sustain even his own weight, and he always proved that what he believed about it was correct.

It is simply a question of mental attitude.

For a suggestion to be assimilated as a self-suggestion, there must be confidence that **amounts to a conviction,** before it will reach and influence the subconscious realm. The great realm of subconsciousness, which corresponds to the functioning of **at least nine-tenths of an individual's psychic powers,** is amenable to the suggestion of the conscious beliefs of the individual. **His mental attitude,** if it amounts to a conviction, evokes or calls forth latent powers or inherent psychic activities, and renders the reserve energy available or useless as he has confidence or lack of confidence.

But suggestion without hypnotism is effective in its influence not only upon the **voluntary nervous functions,** but the involuntary functions as well. **Through the influence of suggestion** upon the physiological processes of the body, **even gross structural changes** can result.

I walked up to a physician upon one occasion who was holding the hand of a little boy in both of his own, gently manipulating his hand. He was assuring the little fellow **that those warts would go away,** that they would go away when he did not know anything about it, and in two months would be gone, etc.

The physician had attended my lecture and demonstration the previous evening, and when I discovered what he was doing, I exclaimed, "Using suggestion so early, doctor?"

"Oh, this is my own method of curing warts," he replied. "I enjoy the enviable reputation here among the little boys as being **the wart cure doctor,** and I have in numerous cases dispersed them by suggestion."

A well-known physician related to me an experience of his in the case of a uterine fibroid—yes, a fibroid tumor of the uterus! Upon his last examination before an **intended surgical operation,** he found that there was much adhesion, and rather than jeopardize the life of his patient, he decided upon a plan which he executed as follows:

"Mrs. Blank," he said, "if you will co-operate with me for one year, I feel quite certain that you can get well without the operation I intended. It will all depend upon your intelligent, persistent co-operation and effort. I **wish to see you once a week** to apply a medicine to the inside of your womb for the influence that it will exert upon lessening the circulation in that tumor, and also to apply a tampon to hold up the heavy organ so that you will suffer no more pain. **Now, what I want you to do,** in dead earnest, is this: Whenever you think of your condition at all, say to yourself, 'The blood vessels that go to this tumor are drying up, shrinking up, getting smaller and smaller, my womb is getting lighter and lighter and this tumor is going away. Every day and night it is going away."

"Doctor Blank," exclaimed she, "are you a Christian Scientist? Do you mean to tell me that any such mental attitude on my part could exert an influence upon a large, hard substance like the things you showed me in those jars?"

"No, madam, I am not a Christian Scientist," said he, "but I do know that persistent, intelligent use of the higher brain centers exerts a wonderful influence over the vasomotor neuro-regulation of the blood supply to any part of the body upon which attention is centered, and I tell you frankly that if you will do as I advise you, I expect to avoid the necessity of this operation."

"Doctor Blank," replied his patient, earnestly, "I will **persistently** and **constantly** do some of the finest thinking that any person ever did, all the time while I am awake and when I retire at night. I will affirm and iterate that this tumor is drying up and shrinking up, that the blood vessels are getting smaller and smaller and that the tumor is getting lighter and lighter and is rapidly going away, day and night it is going away."

This physician saw that patient once a week and made a simple application to her womb, but each time assured her that the congestion was being relieved, that the blood vessels were getting smaller, that her womb was getting lighter and that she was progressing nicely in every way.

He said that at the end of one year that woman's tumor was less than one-fourth of the original size. His patient at that time said, "Oh, doctor, it is such a responsibility to have to keep forcing that suggestion upon the involuntary physiological processes all the time."

"Then dismiss it, madam, just as I am going to dismiss you. I am positive that you will experience no more trouble and you may think of yourself as being a well woman."

It was two years since he dismissed that patient and she had experienced no more trouble.

While upon this phase of the subject, let me state here that **the sexual instinct and its development** is a far more potent factor in the production of neurotic symptoms than is commonly supposed. Nothing so disturbs the tranquility of the average mind as the belief in his or her own sexual weakness, though it is purely imaginary.

That one individual, however, has a nose that is conspicuous for its enormous convexity and another for its concavity does not prevent this organ from performing its function. **So in the case of the female uterus,** which is probably the organ that varies more than any other in position and size and the fact that in one case the fundus points to an angle of forty-five degrees forward when the individual is in the erect position or forty-five degrees backward in another individual is no ground to give rise to a diagnosis of abnormality or disease.

This organ is also from its very nature subject to a great variety of vascular changes and when a patient is morbid in the belief that she has some serious uterine affection with all the perverted mental states that accompany such a self-consciousness, **there is no field of work** in which suggestion in conjunction with some simple application or device brings such fruitful results.

Get the confidence of your patient; let her know that you are considering her case from every point of view; find out what she believes about her case and do it tactfully, and then give her a scientific analysis of her case in your own language that will har-

monize with her own convictions and her symptoms, and in making a mental picture to her as to what the outcome of the treatment will be, be sure to cover every symptom.

In other words, in conjunction with your local treatment be sure to give a suggestion to meet every indication, letting your patient feel that the treatment will bring such results. While using suggestion in conjunction with your treatment, do all you can to secure the intelligent co-operation of your patient.

In all gynecological cases there is more or less functional and neuropathic disturbance, such as insomnia, nervousness, indigestion, constipation, despondency, etc., which can be successfully combated by simple suggestion given at the time the local treatment is applied. Above all send your patients away **less self-conscious of the seriousness** of their illness and more confident of a complete recovery.

A casual remark, while holding the attention of your patient, that she will be easy after this, will sleep soundly at night, have a better appetite and feel better in every way, is food stuff for the subconscious mind **that furnishes memory pictures or ideas** that will be reproduced in the body.

A patient of mine upon one occasion had worked very hard taking stock in a dry goods store and became fatigued. He had not slept the two nights previous, though he had taken fifteen or twenty grains of sulphonal. **He said when he came into my presence** that he just must have a good night's sleep or he could not undertake the heavy task before him the next day. After patiently going into his case, asking him in regard to appetite, elimination, digestion, amount of water taken during the twenty-

four hours, etc., I remarked, "Well, you will sleep if you take a dose of this prescription at bedtime and follow other directions."

I advised him to go at once and drink two glasses of water and repeat this in two hours, and again at bedtime and also insisted that he take **a long walk before going to his home,** all of which I explained was necessary both to encourage elimination and to drive the blood away from an overworked brain.

I then gave the following directions: "Now, take notice, Mr. Blank, if you are not willing to go to sleep tonight, don't take this medicine, **for if you take it you are going to sleep.** Be sure to explain to your wife that you are taking something to give you a good night's rest and that your bedroom must be kept as quiet as possible.

"After preparing for bed, shake the bottle thoroughly and fill a tablespoonful of the medicine and then swallow it. Then put out your light, get in bed and turn yourself loose," (showing him how to relax). **"By slightly breathing through your mouth,** you will take into your lungs more oxygen, which greatly facilitates the action of this medicine. In less than a minute after you relax and breathe deeply, you will feel your arms and lower limbs getting heavy and experience a sensation as if you are sinking down in your bed. **This is the effect of the medicine,** don't resist it; and in less than three more minutes you will be sound asleep and sleep soundly all night and awake in the morning feeling much refreshed."

I then arose and turned to the door in a way that suggested to him to get on out.

"See here, doctor," said he, "there is no danger in this medicine?"

"It will put you to sleep, Mr. Blank, but if you had a weak heart it would strengthen it and all bodily functions will be encouraged and you will have the best night's rest you ever had in your life. Be sure to **remember to relax when you get in bed and breathe slightly through your mouth.** Come tomorrow and tell me how well you slept."

I had prescribed fifteen grains of trional in thirty-two doses of carbonated water, less than one-half grain of the medicine to the dose, when he had taken fifteen or twenty grains of sulphonal at each dose the two nights previous and had but little sleep.

The next day he returned and asked if there was any danger of getting in the habit of taking that medicine, reporting that he had slept soundly all night long and stating that his wife had said he had not slept so soundly before in thirty years.

"Some people are very susceptible to that dose, Mr. Blank, and **I see you are one of them.** Don't you notice what a sedative effect it has had upon you?"

"Yes," he replied, "I feel a little lazy."

"That is simply the result of **a good night's sleep** and the relief that the medicine has given to the nervous element in your case. You will not need another dose of that prescription oftener than once a week. **You will be thirsty** and drink plenty of water after this and that encourages all functional activity. **You will eat more,** digest your food, and improve in health in every way, but you must relax at night when you retire and breathe through your mouth, for the increased amount of oxy-

gen taken into your lungs which is secured in that way is very essential to the success of this treatment."

The fact that he did relax and breathe slightly through his mouth, with the idea having been strongly put to him that he would go to sleep, virtually amounted to getting him to hypnotize himself, or take a suggestion both consciously and subconsciously. **In five weeks he reported** that he had taken five doses of the placebo prescription, had slept well all the while, and had gained six pounds in weight.

Two years later he reminded me of the marked benefit of that prescription. "You know how I had for several years suffered with indigestion," said he; "now I can eat boiled ham, hard boiled eggs, and cheese for supper, and sleep well, all night. **I have gained thirty pounds** and am in better health than I have been in over thirty years."

I am personally acquainted with two physicians who have for some time been engaged in sanitorium work. One of these physicians **secures a good night's rest** for his patient by directing the nurse very seriously in the prescence of his patient to give a "sleeping capsule" (a placebo) at nine o'clock and if his patient is not sleeping soundly by ten, to give another. "But in no event to give more than two. She will sleep soundly all night."

"In fifteen years," said he, "I do not remember that this has failed to secure a good night's rest in more than a half dozen instances."

The other physician instructs his nurse to prepare his patients for sleep by looking after all possible requirements, mak-

ing the patient conscious that he is being prepared to get a dose of medicine that will make him sleep soundly all night, and then directs her to administer one drop of a solution of potassium bromide, instructing the patient that he will be asleep in five minutes and will sleep soundly all night.

Said he, "**That is the last** I ever hear from them. **They sleep all night.**"

Hundreds and hundreds of physicians have reported to me that they secured a good night's sleep for their patients by giving a hypodermic injection of pure water.

A few days ago I came in to the presence of a gentleman suffering with an acute pleuritis with a rising temperature and a severe pain. He was walking the floor, holding a hot water bag to his painful side, and stated that he had been unable to lie down on account of the severe pain. **I advised that he lie down,** relax every muscle, breathe slightly through his lips, and stated that he would at once get easy and go to sleep.

He was left alone and **conformed to the conditions** and did get easy and went to sleep promptly. I assured him before trying the method **that the thorough relaxation** would allow the blood to circulate evenly throughout his entire body and thus relieve the congestion in and about the inflamed area, and that he would get easy and go to sleep. He intelligently and consciously acted upon the suggestion and got good results.

Upon one occasion I was called hurriedly to see a patient after several attempts had been made to secure my services. **She was a neurotic woman** who was reported seriously ill. I had seen that patient before, however, and picked up a bottle

of Avena sativa, a sample that had been left in my office, and carried it along with me. **My patient was extremely hysterical,** almost opisthotonic and shaking convulsively, hands cold, feet cold, pulse rapid and around her was a badly frightened family and friends. As I came into her presence I expressed a regret that I had been so long delayed, and taking her hand sympathetically, expressed the hope that she had not suffered on account of my delay. Whereupon she displayed all of her symptoms with **exaggerated emphasis.**

Her husband and the chief attendant had their say in describing the severity of the attack and related the special incidents that had transpired during the past hour or so and at the proper psychological moment I said to her strongly, "Now, be patient and let me find out just what is the trouble."

I had seen that patient before and my familiarity with her case did not require any further light to correctly interpret her symptoms. However, a physician must sometimes pursue the course that will best secure the accord of the patient in order to get best results. **I took her temperature,** counted her pulse, percussed her chest, listened to her respiration, examined her lips and the lobes of her ears, etc. I then said to her, at a moment when I had her attention, "Be patient, madam, I have just what I need to relieve you in a few minutes," holding the sample of Avena sativa in my hand before her.

Turning to her husband I requested him to bring me a glass of water, an empty glass and a spoon. While waiting for this I said to her kindly, "Be patient, you will soon feel all right after you take a dose of medicine." I poured **one spoonful** of the

medicine into the glass, followed by **six spoonfuls of water,** and stirred it briskly for at least nine seconds. Then taking a spoonful of the mixture, put it to her lips and told her to swallow it down.

Handing her husband the glass I placed one hand over her eyes closing them gently, and requested her to breathe through her mouth. "Now, breathe deeply; once again; now again, away down deep;" thus getting three full respirations. **"There, now, you are relaxed perfectly all over.** Now lie still and let the medicine have its effect, and in ten minutes you will feel all right and be quiet and easy from head to foot."

She lay perfectly still and her husband with eyes as wide open as full moons exclaimed, "See here, doctor, that seems to be a very powerful medicine you are using. Is there no danger in that dose?"

"Just what she needs," I replied. "If her heart were weak that medicine would strengthen it, her nerves will become steady and quiet and strong. Her muscles will completely relax, her hands and feet get warm and her head get easy, and her nervous equilibrium will be completely re-established."

I walked out of the room and requested that he follow me and leave her quiet for ten minutes, stating that she would be completely relieved at the end of that time and that then we would give her another dose and she would go to sleep and sleep soundly all night.

At the end of ten minutes we returned to her bedside. She lay as passive and still as a lake without a ripple. Taking her wrist, I found her pulse about seventy instead of one hundred

and twenty as it was upon my arrival. "Open your eyes, Mrs. Blank, **you feel good, don't you?"**

"Oh, doctor, I could feel the effects of that medicine coming over me **just as you said it would.** I never had anything make me feel so pleasant in all my life."

"It has had a delightful effect, but I never gave a dose of medicine in my life that did not have a good effect on you. You are one patient that I can just know that every dose will produce the desired result."

"Because you understand my case so well, doctor," was her suave reply.

That was all right. Throw bouquets at your patients and they will throw them back at you. Blame them and find fault with them and they will blame and find fault with you.

In the case of the patient just described I advised that another dose of the medicine be administered and for everything to be arranged to let her go to sleep, casually remarking that she would sleep soundly all night and be feeling all right in the morning. My patient remarked that she came near going to sleep anyway from that one dose, and that if she had not been afraid that I would have left her, she would have gone sound to sleep. I left instructions that **she come to my office** the next day and gave her a prescription with several names that amounted to nothing, on account of the smallness of the dose of each, instructing her to take a spoonful in water before meals and at bedtime, suggesting to her that this would keep her nervous system functioning properly; that it would make her sleep soundly at night and prevent another one of those attacks.

At least three-fourths of the adult population of the world are relying upon some therapeutic system or method. They are followers of some herd, school, or system, that offers health in the place of disease. The self-conscious intellectual ego has not been sufficiently evolved within them to enable them to rely upon themselves. **What these people really need** is education, knowledge, and guidance—other names for suggestion—to give them the will to dare to do as well as they know how.

A large percentage of these functional and neuropathic conditions would get well of their own accord if the people were only level-headed enough to do as the dog does, who lies down and gives Nature a chance to recuperate an outraged physical constitution.

Rest in a comfortable bed, deep inspiration of pure air, light, wholesome diet, copious draughts of water to encourage elimination, with unyielding faith in the powers inherent within the biological elements, would result in a cure of a large proportion of the usual ills of human beings without a drop of medicine.

Yet, suggestion begets faith, confidence, and belief, and is at the bottom of Christian Science, osteopathy, patent medicine cures, electrotherapeutic quackery, magnetic healing, divine healing, mental science, metaphysical healing, faith cures and such like. **These people are here** and their methods are applicable to a large class of functional and neuropathic conditions. They are alert and active and here to stay as long as time lasts, under some name or guise, to make use of this psychological method of treatment.

We as a profession should not lay aside one single therapeutic measure or device, but in addition to our ordinary therapeutic measures in all classes of diseases and conditions, we have an opportunity to give our patients the benefit of this most powerful therapeutic adjunct. **Honestly and earnestly convince thinking people** of the utility of any good thing and they will endorse it and give you their hearty co-operation, it matters not how strong their prejudices may have been.

Physicians frequently make a serious mistake by discouraging their patients with an unfavorable prognosis instead of relying with more confidence upon the psychic element which would furnish them a rational basis for a more hopeful result.

A young lady of my knowledge was taken seriously ill with pneumonia and a pessimistic, brutally frank physician, at his very first visit told her family that she was going to die.

After his second visit, an aunt of the young lady went to her with the physician's prognosis and told her that she must die. The girl had slept a good part of the previous night and a visitor at that house who had the case under observation had not felt uneasy about her, neither had she been seriously concerned in regard to her recovery.

"Won't somebody say that I can get well?" was the wail that went up from the frightened girl in reply to the cruel message delivered by her aunt. "Oh, if somebody would say that I could get well, I would not have to die," she continued.

The stern aunt, who conscientiously believed that the girl should know that the worst must come, in order to give her time to face the problems of the great beyond, poured into her

ears the poison. "The doctor says you must die. You can't get well. We want to tell you the truth and give you time to prepare to die," etc.

No human being in that condition can stand that kind of psychic influence and live. Every nervous function became disturbed. The machinery of the entire nervous system was shocked and she did not sleep any more for the next two nights and died on the third day after the physician **had read her death warrant.** All this time she begged, "Won't somebody say that I can get well?"

There are many fatalities occurring daily all over our country for the **lack of men with faith in this psychological law** and courage and moral stamina to stand out against the popular prejudice to it and apply it as a therapeutic aid.

A number of times in my life has it been my unpleasant duty, yet high privilege to have an opportunity to stand by a patient, in the face of a positively unfavorable prognosis, made by those who did not appreciate the great power of suggestion upon the subconscious, and tell him, **"You are going to get well."** I have had such patients squeeze my hand as I held theirs and say, "If you stand by me, doctor, I will get well."

All classes of illness, sickness or disease, in conjunction with other methods of treatment, need moral or psychological support. They need leadership. **We need men in the profession to do as Napoleon did,** when his men were dying by the several hundred each day on his march in the east. He visited the camp and took each one by the hand and assured him strongly and positively that **if he would be brave, he would get well. As**

this one visit of his to the sick and discouraged soldiers, put an end to an epidemic where several hundred men were dying each day, so would many human lives be saved by this simple suggestion given with confidence and with conviction, in conjunction with other therapeutic measures.

The medical profession have been looking too long at the surface of things. We have dealt too much with externals, with effects, and have neglected causes.

There are three-fourths of the human race who need arousing and being shocked into a self-consciousness of strength and ability, confidence and determination. Not only in facing the questions of health and disease, but in all other problems of life. The man who gives such patients some of his own optimistic personality is giving them strength and life itself. They convert countless millions and millions of brain centers, lying dormant and unused, into action to encourage every bodily cell to increased function.

The trouble is that the majority of people have not sufficient confidence within themselves. They do not recognize their power and have no confidence in the latent potentialities dormant and unused within them, that can only be called into action through faith and confidence. A new self-consciousness needs to be awakened within them. The great majority of people are incapable of thinking and reasoning for themselves. Their minds through education and experience have not had the foodstuffs to enable them to exercise reason. They are governed by fear and ruled by emotion. Others go through life in a listless, dream-like, mental condition, referred to by Jastrow as mental loafing.

The will is only capable of reproducing those impressions made upon the brain through experience and education. Whatever idea is uppermost in their minds, whatever impression is the strongest, is the one that most influences them.

The physician who is so engrossed in the pathology of the case that at each visit he recites it over and over again to his patient, assists in encouraging not the patient, but the disease. **He fastens the morbid psycho-neurotic element** of the patient stronger upon him, and thus intensifies his disease by lessening his resisting powers.

People are hypnotized by their beliefs. Belief in an idea or a theory or a creed or a drug or a man or a woman is the place where the individual relinquishes self responsibility, takes mental refuge, **and agrees to act upon the idea or series of ideas that are presented to him either consciously or subconsciously.** It is all a matter of getting the confidence of people and making suggestions.

"Get off the grass, get off the grass," is a sign that one sees everywhere in the study and application of this subject. It is before the door of the prevailing educational systems, political and economic problems, religious and therapeutic creeds, orthodox and heterodox alike, all mould and shape the actions of men by the use of suggestion in disguised form. **How sensitive** people are when we tell them the truth!

Three years ago in one of our northern cities a gentleman invited me to attend what he called a remarkable hypnotic exhibition. It was the last service of a ten-day religious revival meeting in a tent with a capacity for fully five thousand people.

The last song had been sung and the last prayer offered before the speaker appeared upon the platform.

He walked up and down before his audience **as if heaven and hell, life and death, time and eternity** were all on his shoulders. He then struck a pose, by the side of his little stand, that itself filled his audience who were already under the influence of his suggestions, with expectant awe and fear. **With all the intensity of a tragedian** he then began: "There are people under the sound of my voice here tonight that before this hour is over will have made a record for hell or heaven! There are people under the sound of my voice that before another year has rolled around will have approached the judgment bar of God!" **One strong expression after another** of this kind followed, and in less than three minutes a little woman with an unstable, nervous organization near me dropped upon her knees with the cry, "Lord help, oh Lord, save the people!" etc.

On and on went the suggestor, the pulpit orator, the speaker, the hypnotist, and one after another followed the example of the little woman until within twenty minutes pandemonium reigned. The whole tent reverberated the echoes of crying, shouting and praying.

I walked up close to the leader and noted that he went from one to another and suggested what the Lord would do and what the penitent must do. **To one he suggested,** "Just get up and say glory hallelujah. It's all right." For at least forty times the poor fellow jumped up and clapped his hands and exclaimed, "Glory hallelujah, it's all right!" Dozens of others were playing their stunts in different ways.

This was in one of the **most enlightened and cultured states in our great union,** and this was a tame affair to some experiences that the writer has witnessed **in his own southern State, both among whites and negroes.**

Any method of getting an individual to **act upon an idea or a series of ideas,** be they true or false, either consciously or subconsciously, is hypnotism or suggestion. **Suggestion,** then is a basis of all religions, creeds, dogmas, non-medical and non-surgical therapeutic systems, and all methods of education.

"Keep off the grass, keep off the grass," however, is found posted everywhere by people who live and thrive upon the ignorant credulity of their fellow men.

Suggestion is used both for the good and for the harm of human beings. It is used by everybody and the really dangerous man or woman is the individual who is unconscious of its potency as a factor in both sanity and insanity, happiness or unhappiness, education or ignorance, truth or falsehood, health or disease, character building or moral perversion.

We frequently see fanatics upon various lines, swaying and leading men and women into all kinds of incongruous paths and actions by their fanatical zeal, enthusiasm and absurd devotion to some false theory or concept. **The only protection for the individual** is knowledge and experience, education and light, and the ability to think for and protect himself.

No special tact is required by a physician to use suggestion to fix the attention of his patient on such ideas as are desirable to influence his life and conduct for therapeutic purposes. **The**

great thing to be desired is to have more regard for the welfare of your patient than for the **remuneration for your services.**

We find everywhere pseudo-conscientious men in the medical profession who "have too high a regard for the truth" to use suggestion in a legitimate therapeutic manner for the helpfulness of their patients. **Such men usually fasten a trivial functional disorder** by the injudicious use of suggestion upon the consciousness of a patient and make it a serious psycho-neurotic condition by giving his disease a name and pointing out its serious pathology and consequences, simply giving a prescription to relieve a condition which he has made in reality ten times worse.

A North Carolina physician had a patient who was morbidly self-conscious of some functional disturbance and after going to leading men in several of the larger southern cities, he finally landed in Baltimore where he secured an audience with one of the most widely known physicians in the history of the medical profession. **The patient related his difficulty** in getting relief and told how he had gone from place to place and how the physicians did not agree and how some called his disease one thing and some another. The physician stripped him, gave him a careful examination for two or three minutes, and said, "All right, sir, put on your clothes."

He seated himself to write a letter, and by the time his patient was dressed, he said, "Give me twenty dollars, please," which was promptly handed over to him. Then with one hand on his doorknob and the other on the patient's shoulder, he looked him squarely in the face and said to him, **"My friend, go**

home and read only the book of St. James, call yourself a ——— fool and let doctors alone."

The door was opened and the man was out of the physician's office before he realized it, another patient having gone into the consulting room. The gentleman reminded the office attendant that the doctor had forgotten to give him a prescription and he was informed that he must now wait until all present had gone in before he could have another audience.

Over and over did he revolve that advice, "Go home, my friend, read only the book of St. James and call yourself a ——— fool and let doctors alone." The gentleman grew too nervous to sit still and decided to take a walk and return an hour later, but while walking alone on the streets of Baltimore, blind and deaf to everything that he saw and heard, the meaning of that advice at last dawned upon his consciousness and he began to laugh.

He then decided it would not be necessary to return to the physician's office, and he took the next train for his home, all the while remembering that his family physician had told him that his disease was more "in his head" than otherwise. The meaning of the advice given by his family physician was now clear to him and he realized for the first time that he did not have a brain disease, and that what the eminent physician really meant was that his condition was the result of an unbridled imagination, or to speak in modern psychological phraseology, due to a morbid self-consciousness.

He reached his home with his head up, wearing a smile like a headlight on a steam engine, and though three years had

elapsed, the gentleman yet laughed at how easily he had been cured by finding a man with courage and honesty sufficient to tell him that he had been acting a ——— fool and should let doctors alone. **No doubt, he also was instructed** to quit reading patent medicine advertisements, and modern mind cure theories.

Now, that is just the point. **People so often need advice,** assurance, ideas, persuasion, or shocking, other names for suggestion, and not medicine or instruction in the pathology of their disease. **The fact that a patient comes to you** is ordinarily an acknowledgment that he is willing to take your advice, that he has confidence in you and is willing to rely on your judgment.

Here I would add a word of caution. It is a great mistake to tell a patient that you can find nothing the matter with him; almost as bad as to exaggerate the seriousness of his symptoms. **An individual with a functional disorder** may not necessarily be suffering with insomnia or have sustained a loss in weight and yet be in the incipiency of a disease which, if not properly treated, may result in serious disorders of metabolism. **He comes to you with subjective sensations,** feelings and impressions which annoy and depress him. He feels incapacitated for his work. **Every problem of life is colored** by the hue of his morbid subjective state, and when you tell him that you can find no cause for his trouble you only add to his morbidness and aggravate what may be the incipiency of a grave disorder. **A good proportion** of the more serious nervous and mental diseases begin in functional disturbances. The disorders of metabolism resulting in metabolic toxemia may begin in this way. **These patients should**

be made to feel that they have your confidence and sympathy, as well as the benefit of your knowledge and skill as a physician. Then you are in position to tactfully govern their habits of thought and conduct and to help them to execute a plan of treatment that will bring about recovery.

Elimination is usually deficient and the treatment needed in such cases tests the complete resources of the physician and embodies all therapeutic measures, medicinal, dietetic, physiological and mechanical, as well as psycho-therapeutic.

Frequently work under the proper conditions, is the only means of cure, and the far reaching influence of the physician to secure the conditions necessary for the recovery of his patient is not out of place.

The proper treatment of disease is **as varied in its application** as is the wants and necessities of mankind.

Illustration.—A physician of my acquaintance was called to see a frail little woman who was the only support of her two fatherless children. Day and night she labored with needle and thread, vainly striving to buy food and clothing, pay rent, and provide for other life essentials. **Deprived of fresh air and sunshine** and under constant mental and physical strain, she finally succumbed, with all bodily functions disturbed and discouraged and depressed in the extreme.

The representative of a local church organization stated to the physician that they had provided a nurse, arranged for her medicine and would send her nicely prepared meals and visit her often.

"All that will only add to the severity of her psycho-neurotic condition," said he; "go and get her $25.00 to **pay her house rent, fill her pantry with substantial food** to meet present demands, but above all secure her **a position where she can work** and get exercise and sunshine and fresh air and have time to sleep at night and she will need no medicine, no nursing, or visitors."

The representative of the charitable organization left saying that she would have the society consider the matter at their next meeting, a week hence.

There was present at that interview between the physician and the representative of the local organization, a stenographer, who was the widow **of a poor young physician** who had died, leaving her with no means of support, but before her marriage she had learned to "do things with her hands," and she was independent and happy. **She requested the physician** to meet her on the outside of the sick lady's room at 7:00 o'clock that evening, at which time **she delivered to him** the amount of cash requested, and had unloaded the substantials for a well filled pantry and announced that **she had secured a position** for the sick lady in question, all of which she had done quietly and unostentatiously during the day, requesting that the part which she had played in the matter never be disclosed to the patient.

Within a few days that frail little woman was at her post of duty and **up to four years afterward** she was at work, much improved in health and strength, contented and happy.

Such was the result of the efforts of a woman who was willing to help her weaker sister to help herself.

The **true physician** faces the problems of his patients with impartial and impersonal courage, and with the tenderness of one whose own heart has felt the pressure of these tremendous questions; one so full of love and sympathy for his fellow man, full of cheerfulness, full of strength and optimism and full of helpful hope "That he can move on human life as stars move on the dark seas of bewildered mariners."

CHAPTER VIII.

HYPNOTIC SUGGESTION.

So far I have endeavored to show that hypnotism is nothing more than getting an individual **to act upon an idea or a series of ideas,** and **to execute them either consciously or subconsciously.** The name matters not except to those who desire to appeal either to the credulity or ignorance of their fellows.

My observation has been that **the physicians** who object most strenuously to the use of suggestive measures, both with and without hypnotism, are the ones who are really doing the most to hypnotize their patients into a serious illness, rather than using suggestion and every other available means to help them get well, and keep well without relying on a physician.

The theologian who raises the greatest objection is the man who is hypnotizing his audience into believing some questionable dogma by an appeal to the emotions, rather than by keeping abreast with the investigation of science and preaching a sane, rational religion that appeals both to the heart and to the intellect.

The educator who most strongly opposes it, is usually the man who is making a great bluff to conceal his own lack of moral stamina or his ignorance.

With the prejudice that exists against the use of suggestive therapeutics by the selfish and uninformed element of our population, from the highest to the lowest rank, I am truly sorry

that there is so much of meaning in the application of suggestion in its relation to the practice of medicine.

I can but wish that man were **a machine** to be dealt with in a cold, perfunctory manner, or that he **were a cabbage** instead of a human being, **or a tree** that needed to be pruned and fertilized and relieved of parasitic infection and then left alone to see what he would do.

But we cannot get away from the facts that man is an **organism** composed of millions and millions of cells that are susceptible to external stimuli; that these can be stimulated by **any impression that reaches the consciousness** of the individual through any one of the five special senses; that the higher and lower bodily functions are so inter-related that **any impression that reaches the higher centers** is in turn transmitted to the lower bodily functions; and that through these, every function in the body and every cell can be influenced.

We cannot forget that man is a sentient being with **intellect** and **feeling** and **emotion,** which are the highest characteristics of a human being; that constitute the distinguishing differences between him and the lower forms of animal and vegetable life. These cannot be ignored in our consideration of the individual, composed as he is of mind and body. *Ignorantia legis neminem excusat.* **Every physician, clergyman, educator,** or **other human being,** is playing and toying with these evolutionary factors of human personality by every idea or impression conveyed to the human mind, whether he realizes it or not.

Alas! Too often in his refusal to exercise sufficient regard for the truth, he sets himself in open **opposition to the highest**

and best interests of the health and happiness of all individuals with whom he associates. **Often,** yes, thousands of times and oftener, have I heard physicians refer to suggestion, both with and without hypnotism, and say, "There is nothing in it." These are men who belong to a "learned profession," who are educators and leaders and teachers of the people!

A successful neurologist in one of our larger cities, who considers the greatest element of his success for the last fifteen years due to his employment of suggestive therapeutics very charitably remarked that physicians who opposed these methods really **do not know any better,** and in their ignorance could not be blamed.

In the consideration of any therapeutic measure, the first thought that comes to the mind of the wide awake physician is, what is its advantage over any other method of treatment?

The answer to that question is easy: Its addition to other therapeutic measures enables the physician to **get results** in a very large proportion of cases that come under our observation, **that cannot be secured** through any other agency. The value of any therapeutic adjunct is in direct ratio to the successful results that accrue from its administration. Yet, it must be remembered that **what are possibilities** with any method or kind of treatment, medicinal, surgical, suggestive, or otherwise, are **not always actualities** in the hands of all men alike, and it depends upon the individual and upon him alone, rests the responsibility for what he is not able to accomplish when he is really **put to the test** at the bedside, and this often seriously disturbs our conscience and humbles our pride.

Any physician who expects to use suggestive therapeutics successfully must by practice acquire that confidence in his own ability to succeed with it by familiarizing himself with all the facts and theories and details of his subject.

Yet, I have often noticed an individual who possessed that **inexplicable quality of personality** to get others to do anything he wanted them to do, who had never read a line in psychology or suggestion and was absolutely unfamiliar with the principles of medical science.

Hypnotism is a self-induced psychological condition. You do not hypnotize an individual, you simply get him to do it himself; but to get anyone to act upon an idea or a series of ideas, either consciously or subconsciously, one must **be in dead earnest,** exercise a little enthusiasm about the undertaking and go at it with the will to succeed.

The greatest essential to the application of suggestive therapeutics is a **conviction on the part of the operator** of the value of the treatment as applied to the case at hand and a desire to bring about the recovery of the patient. In fact, this is the important essential which is the *sine qua non* to the success of any kind of treatment.

Yet, if suggestion be of value at all it is of use just in proportion that the individual **accepts and carries out the suggestion** both consciously and subconsciously. **Hypnotism** is but **the art or technique** or method of instructing an individual to act upon a suggestion or a series of suggestions. **There must always be a conscious acquiescence,** consent, or co-operation, on the part of the individual, **not necessarily to be hypnotized,** but to take

the suggestion, which is the same thing. Then by suggestion there is induced in the patient a new consciousness whereby he is led to do that which he had previously been unable to do for himself both consciously and subconsciously.

In a preceding chapter I spoke of using suggestion to **inhibit the conscious mind,** as was hypothetically supposed to be accomplished in the hypnotic state. **It would have been more correct** to state that we simply get the patient **to be passive** and allow the operator to induce **a new consciousness** and then to direct the stream of consciousness which produces mental states that react upon every bodily function.

We get our patient to let us **direct and control his psychic activities** and teach and illustrate for him how he can direct and control them for himself. We put our patient **better in control of himself,** all dependent upon the suggestions or sense impressions that are transmitted to his brain cells through the senses while in this passive or suggestible condition. What else does education or theological sermonizing or instruction upon any line accomplish?

Sense impression is the starting point for every psychic action. Every sense impression that is produced by suggestion or otherwise has a determined localization in the brain cortex.

It is assumed by psychologists that every sense impression, according to its degree of strength, produces a molecular change in the nerve cells influenced, which gives rise to the possibility of a reproduction of these ideas or sense impressions by an internal process.

Memory is the result of sense impressions that previous experiences in life have left upon the brain cells. The very ideas or products of thought which are stamped upon the brain cells by suggestion in the hypnotic state, as well as by suggestion without hypnotism, have the **power of being reproduced in mental states,** which gives rise to a new consciousness in the individual.

By suggestion in the hypnotic state we are better enabled to plant sense impressions, ideas, thoughts and feelings which reproduce themselves in the consciousness of the individual and furnish a foundation for his intellectual activities.

In this suggestible condition, we are enabled to drive back certain sense impressions that create unpleasant mental states, obliterate them and wipe them out, and by holding the subject's attention to certain ideas presented to him, **we create a new consciousness** or alter his frame of mind. We render the individual **more self-conscious of potentialities,** dormant and unused within him, which he can call into operation through the combined effort of memory and will, in contrast to previous conceptions of his own personality. **This new conception of himself** and his relation to the outer world contributes to strengthen and develop the self-conscious ego. It is in reality **the development of the ego.**

By suggestion in the hypnotic state we give impulse to reproduce previous sense impressions. Call it strengthening memory or will or character or ego, as you choose, **and the mental process which brings about the logical connection** of sense perceptions or ideas reproduced in this way, **is what is called thinking.**

So, then, by suggestion in the hypnotic state we create new thought habits, mental states or streams of consciousness which react upon every bodily function. We alter the individual's thinking.

The following cases will illustrate the position taken by the author as to the value of suggestion in that condition of induced passivity or receptivity to suggestion commonly referred to as the hypnotic state. **Whether the individual is asleep or not** does not concern us here. It suffices if we have the confidence and co-operation of the patient.

The physician who fails to avail himself of the great therapeutic value of hypnotic suggestion to his patients, in well selected cases, for the relief of conditions and symptoms **that cannot be alleviated by any other method of treatment,** refuses to employ one of the most powerful therapeutic adjuncts available at the present time.

The results obtained by hypnotic suggestion in the following cases **speak for themselves:** I shall only cite enough cases to illustrate the position taken by the author in the preceding pages.

INSOMNIA.

Loss of sleep is a condition that leads to general physical disease. It has innumerable causes, all of which should be considered and treated according to indications, which calls into exercise the complete resources of the physician. It more or less accompanies all diseased conditions, acute or chronic, functional or organic, surgical and otherwise.

It is useless to attempt to break up the habits of nervous, wakeful people by suggestion when the individual lives in open violation to all the known laws of health, or where the system is overloaded with toxic products due to indigestion, caused by overeating, with fermentation, deficient elimination, etc.

Meet every indication in the individual case at hand and, in conjunction with other sane, sensible, rational advice or suggestion, hypnotic suggestion will prove indispensible in many cases.

Make it a rule to **regulate** your patient's **diet, his drinking, and his habits, as well as his thinking.** The question of food and drink habits, etc., will be briefly considered in a separate chapter.

However, there are numerous individuals among all classes **upon whom the cares of life have borne heavily,** who, try as they will, with their imperfect knowledge of self-control and lack of self-reliance, cannot keep back subjective impressions which crowd themselves upon their consciousness when they retire for sleep, and the darkness renders them more conscious of their trials.

Many there are who are still waiting for special divine intervention to satisfy them that their souls are saved. Doubt hovers over them and disturbs their peace of mind. **Others have not learned** the beauty and glory and salutary effects of work and useful employment as a means of strengthening and developing both mind and body.

An unoccupied, idle brain is the reflector of a morbid imagination upon which flit and dance all kinds of annoying mental

pictures to the discomfort of the individual who fain would find relief in sleep.

In rare instances an over-expenditure of nerve energy, through work or worry or dissipation, prevents the individual from possessing that inherent quality of nerve force sufficient to exercise self-control. **Uncontrolled emotions,** in the form of sentiments both selfish and altruistic, also contribute their influence to keep awake the restless neurotic.

An irritable nervous system, either hereditary or acquired, is transmitting constantly afferent and efferent impulses to and from the brain, and throughout the entire human frame subjective sense perceptions are interpreted by the individual as nervousness, sickness, pain, disease, etc.

Nutrition is disturbed and toxines of metabolism, or more properly catabolism, are being manufactured to poison all bodily functions and prevent the normal formation of "opsonins."

TREATMENT.

In conjunction with dietetic, medicinal and **hygienic treatment,** suggestion in the hypnotic state should be used, if necessary.

Get your patient to **relax every muscle** and **breathe deeply and rhythmically** for several times in succession, and then with one or two drops of chloroform or any other placebo, or without them, as you choose, tell him that you are "going to put him to sleep, that as you apply this remedy he will get quiet all over, get drowsy and sleepy and go to sleep, and awake feeling better."

Then to hypnotize him, make suggestions as advised in the chapter on the **technique of inducing the hypnotic state.** After

he is hypnotized, while you sit beside the unfortunate whose nervous system you have soothed into quietude and passivity, talk to him, using suggestions somewhat like these:

"You are resting quietly, sleeping soundly, breathing deeply, perfectly relaxed and passive all over. Now, as you lie in this passive state with all tension relieved, while I am talking to you, you feel your nerves getting steady and quiet and strong. **All nervousness is going away** and by the time I count ten, your nerves will be quiet and steady and strong all over, your nervous equilibrum will be completely re-established from head to foot. One, two, three, four, five, six, seven, eight, nine, ten; your nerves are steady and quiet and strong all over.

"Now, after this treatment, **whenever you think of yourself,** you will find that your nerves are steady and quiet and strong.

"At bedtime you will relax, close your eyes and think only of sleep. You will go to sleep and sleep soundly all night long. You will awake in the morning feeling refreshed and rested.

"After this you will **be thirsty and drink more water** than ever before in your life. Every two hours from morning until you retire at night you will drink a glass of water. The increased amount of fluid will cause an increased action of all your bodily functions. Your skin and kidneys, liver and bowels, will eliminate more freely.

"You will be easy and comfortable all over. **You will enjoy eating and work and exercise,** and gain in weight and be happier, feel stronger, and be glad that you are living."

I then awake the patient and give him conscious advice

how to eat, how to drink, how to exercise and **how to relax** so that he can go to sleep. I give him a reason for all the advice that I have given, as well as a reason for the suggestion given him in that induced condition of passivity.

I am often asked, "Do you mean to say that the suggestions will be effective just because they are made to the patient who is hypnotized?" I say **we make sense impressions** on **the brain cortex** while the patient is in the hypnotic condition that are reproduced in the individual's thought habits. The reproductions of these ideas are **auto-suggestions.** When you substitute **helpful auto-suggestions** for adverse and harmful auto-suggestions, you have been of the greatest help that one human being can be to another. You have put your patient in control of himself. **You have changed his habits of thinking,** and by this means new habits of thought and action in every day life are formed. You have put your patient better in possession of himself, and better enabled him to meet the exigencies of every-day life.

ILLUSTRATION NO. 1.

Syphiliphobia, Insomnia, Neurasthenia, etc.—Mr. Blank, a farmer, who had led an honorable, upright life, had by his indiscretion contracted a gonorrhoea and a chancroid. The chancroid readily healed, but the gonorrhoea persisted for several weeks. **He believed that he had syphilis,** was tortured by a hypersensitive conscience, and for several months had been confined to his room. His physician had re-assured him, **reasoned with him,** and done all in his power to argue the delusion that he had syphilis out of his consciousness.

He had recovered from both these diseases, but there was **a psycho-neurotic element** in his case which was day by day growing more serious. **He did not sleep at night,** was frequently heard crying and praying, when everything was quiet and all were supposed to be asleep. Anorexia, indigestion, malnutrition, a loss in weight of thirty-five pounds in five months, had caused his physician to feel apprehensive of his soon being a fit subject for the insane asylum. In fact, he was so already.

Here were **insomnia, hysteria, syphiliphobia, neurasthenia, delusions, etc.,** all in one case. I explained to him the value of a new and powerful sleep producing remedy (a placebo), that I was "introducing to the profession," and impressed upon him consciously that there was a nervous element in his case that this remedy would relieve.

I let him know that **it was expected to put him to sleep,** and that the result of this sleep would be to relieve the nervous element in his case. **He readily consented** for the treatment to be used, and went into a profound state of suggestibility.

In the hypnotic state I addressed him about as follows: "Now, Mr. Blank, you are sound and dead asleep, perfectly relaxed and passive from head to foot, breathing deeply, your nerves steady and quiet and strong. **As you lie here** while I apply this remedy, your nerves are growing steadier and quieter and stronger, and by the time I count ten, your nerves will be steady and quiet and strong all over. One, two, three, four, five, six, seven, eight, nine, ten, and your nerves are steady, quiet and strong all over. Now, you will not be nervous any more. **After this, whenever you think of yourself,** you will find

that your nerves are steady and quiet and strong, and you will realize that you have not had syphilis, that Doctor Blank was right, that he knew his business and that you are now well and all right.

"**You will drink water every two hours,** enjoy your meals, sleep soundly at night, and attend to your duties just as you did months ago when you were well.

"**When you go to bed at night,** you will relax just as you are here now, close your eyes and think only of sleep, then you will go sound asleep, and sleep soundly all night long. If you awake at all in the night, it will be to think of yourself as resting and sleeping quietly, feeling contented, satisfied and happy. **You will enjoy your meals** and take the old-time interest in your farm work, your stock, and business generally. You will go to town as you once did and every day feel thankful for the improved condition of your health."

I allowed him to sleep **for thirty minutes longer** and then awoke him. I told him that this treatment had done him good, that he was going to feel better after this, that he would enjoy his meals, would sleep well at night and would attend to his business as in former times. I assured him that he was in sound health, had been well all the time, and after this would feel differently in regard to his own condition.

He came to see his physician five days after that, and, while lank and lean as a pine fence rail, he was his old self, his rational normal self, as he once was before his misfortunes. Five weeks afterward he had gained twelve pounds in weight and was **rapidly on the road to recovery.**

By suggestion in the hypnotic state, **new ideas, new sense impressions** had been substituted, **new thoughts planted** in the place of the old ones that were torturing his conscience, preventing his sleep and damning his life. **A new consciousness now possessed him** and he was practically a healthy man.

ILLUSTRATION NO. 2.

Epilepsy, Chlorosis, Anaemia, etc.—This patient, a girl aged sixteen, had been treated by five leading physicians of her city for several years without benefit. Her case had been diagnosed as true epilepsy, but I had reason to believe that this was a mistake.

She had epileptic seizures from once to several times a week, was anaemic and chlorotic, her menses were scanty and irregular, she had poor appetite and was badly nourished; slept soundly at night, but her sleep was not refreshing. Awoke in the morning tired, and she took but little interest in anything.

Hypnosis was induced and suggestions were given her while in the hypnotic state, to get her to breathe deeper, and it was also suggested that she would **always breathe deeper,** day and night, asleep or awake, that she would always breathe deeper.

It was also suggested that she would **be thirsty after this and enjoy drinking water,** that she would always drink more water, that she would take a glass of water every two hours from morning to night. It was further suggested that she would **take exercise** freely every day, that her bowels would move regularly every morning, that she would go **to the toilet at least twice a day,** and that her bowels would functionate properly, move freely every morning, etc.

In a case like this, suggestion must be given to influence the individual's **conscious and unconscious psychic or mental activities.** Waking conduct must be guided as well as subjective impressions made to influence the involuntary functions.

My lecture to this girl would probably be about as follows, with my hand upon her forehead or gently stroking her forehead from side to side, made in a monotone, positive, earnest manner, presented **in a way that would transmit words into feeling:** "Now, my dear little girl, you are sound asleep, and while you lie here your nerves are getting quiet and steady and strong, quiet and steady and strong, and by the time I count ten your nerves will be quiet and steady and strong all over. One, two, three, four, five, six, seven, eight, nine, ten, your nerves are quiet and steady and strong from head to foot.

"Now, as I talk to you and place my hand upon your chest you feel your ability to breathe deeper getting stronger and stronger, and by the time I count five I want you to breathe deeply, filling your lungs as deep and full as is possible. One, two, three, four, five, now breathe deeply, deeper yet, [she took the suggestion well]. There, now, rest and breathe naturally.

"Now, after this, you will always breathe deeper, the blood will circulate more freely in your stomach and will better nourish your gastric mucous membrane so that you will have a better appetite and a better digestion. Under my hand here, now, you feel the blood circulating more freely in your stomach, and by the time I count five the blood will be coming freely to your stomach. One, two, three, four, five.

"After this you will be thirsty and drink water every two hours and you will be hungry and enjoy your meals. You will chew your food well and especially enjoy eating fruit and vegetables. You will sleep well at night. When you go to bed you will go sound asleep and sleep soundly all night. You will never again be nervous or have another one of those nervous attacks. You will enjoy breathing, drinking water, and eating, working, exercising and sleeping—you will enjoy life.

"As you eat more and digest your food better, you will be better nourished, get stronger, gain in weight and have perfect health."

About six weeks after this treatment by suggestion, which was followed by three others given by her physician, I learned that she had experienced no more trouble and was a great deal better.

Five years after that, her physician, who assisted in the treatment, informed me that she had never had any further trouble, that she at once began to sleep, eat, drink, exercise, gain in weight, etc. "She went from one hundred and ten to one hundred and forty-five pounds in weight," said he, "and is now married and the happy mother of a fine baby."

The therapeutic application of suggestion in hysteria, neurasthenia, melancholia, indigestion, morbid fears, nervousness, etc., makes use of the same principles as were empolyed in the above mentioned cases. Your suggestions **must be made to meet the individual needs** of the patient at hand. **Burn into his consciousness** or subconsciousness the ideas that you wish to influence

both his voluntary waking consciousness and all his or her involuntary physiological processes.

As a rule, **suggest away** whatever subjective impressions, sensations, feelings, thought habits and bodily symptoms that are objectionable, and in their place **suggest what you desire** to influence your patient or become a part of his life.

ILLUSTRATION NO. 3.

Acute Migraine, Neurasthenia, etc.—Telephone girl with acute migraine, but was of neurasthenic and highly nervous temperament at best. Her physician usually began with a hypodermic of morphine sulphate, one-fourth of a grain and atropine sulphate, one-one hundred and fiftieth, and in addition to this, prescribed a brisk purgative of calomel, aloes, podophyllin, cascara, etc.; also hot foot baths and hot fomentations. If constipated, he directed an enema to be given at once.

The girl reached her home at six p. m. in one of her most severe attacks. **At least two days** were usually required for her to get over one of these severe headaches, usually associated with indigestion, and during this time from two to three hypodermics of morphine were required in addition to a dozen doses of coal tar preparations, bromides, etc.

She was a young woman twenty years of age, with an unstable nervous system, and the cares of life were bearing heavily upon her. Her responsibilities were heavy and her work arduous. Her headaches and general collapse were Nature's rebellion against the outrage being daily committed against her weak physical organization. But her suffering was great and she needed help.

Her physician had already recognized the **harmful effect of the narcotics, sedatives, purgatives, etc.,** which were being demanded more frequently and were used each time with less efficacy.

At 6:30 P. M. I went with her physician to see the girl, suffering with an intense headache, nervous, etc. I told her I could rub her head with a medicine that I had and relieve her headache, and that she would go to sleep.

She readily went under the influence of my suggestions, was easily hypnotized, and I suggested that her head was getting easy and her nerves getting steady and quiet and strong, and repeated this suggestion a half dozen or more times, and ended by saying that by the time I counted ten she would be perfectly easy from head to foot, that her nervous equilibrium would be completely re-established.

We allowed her to sleep until after my lecture and returned at 12:30 to find her asleep. She awoke at my suggestion perfectly easy, thoroughly relaxed, in a copious perspiration. I directed that she be rubbed off gently with a dry towel, drink a glass of malted milk with two eggs in it and drink all the water she wanted. She drank two large glass fulls and then I directed that she shut her eyes and go to sleep and sleep soundly all night. **No, I did not hypnotize her again,** for I had suggested in the hypnotic state that she could go to sleep after I awoke her and every night after that whenever she decided to do so.

Her physician 'phoned me that he went by to inquire about her at seven the next morning, but she had gone to her post at the telephone. I 'phoned him that that was cruelty to animals,

for she should have rested that day. What she really needed was shorter working hours, better pay, and more time to devote to outdoor exercise, reading, recreation, etc. But she was in the mill, to have her life ground out of her to enlarge the dividends of an enormous corporation, to be used like corn that is ground to be made into bread to fill our stomachs.

If the medical profession expects to be held in the esteem of the public, which it so eminently deserves, **the physician as an individual should speak out** upon these questions that concern the welfare of our fellow man, not alone in hygiene, dietetics, sanitation, etc., but upon any and all problems that influence the health and happiness of the individual.

ILLUSTRATION NO. 4.

Psycho-neurotic Paralysis.—Mr. F. E. H., by occupation cotton buyer, age fifty-eight. His history was that ten years before he was taken with an apoplectic seizure and evidently had a thrombus, as he was unconscious for several weeks and his arm and leg on the affected side were more or less completely paralyzed.

He was sustained by rectal alimentation for several weeks, but could swallow liquid food after six weeks or two months and after six months gradually began to regain the use of his arm on the affected side, and after one year began to hobble with crutches, dragging the affected leg.

He was then taken **with acute sciataca** and confined to his bed for one year longer. At the time I saw him he had been dragging his foot on the affected side for eight and a half years, but was able to get about with the aid of crutches.

During this time he had tried every available method of treatment offered in hospitals, sanitariums, health resorts, etc., as well as some of the modern cults that use suggestion without hypnotism, in disguised forms.

Hypnosis was induced and suggestions made with a view to implanting sense impressions, impulses, or to inducing a self-consciousness of ability to use his leg. When I held the leg up while he was hypnotized and suggested that he would allow it to remain, he held it up without trouble. He then acted upon a suggestion to lift it up, to bend it, and finally I had him walk around in the room while yet in the hypnotic state. It was then suggested that he would wake up and would find that he could walk as well as he ever did in his life.

It was really amusing to see him find himself using the leg which for ten years he had been unable to lift from the ground.

I have treated over a dozen similar cases in patients who have put aside their crutches and walked with perfect ease. The suggestion given is that the limb is getting stronger and stronger, that the normal control and use of it is returning, etc. Repetition and iteration, iteration and repetition, are very necessary in some cases to make a suggestion or suggestions effective.

ILLUSTRATION NO. 5.

Persistent Vomiting.—A gentleman fifty-eight or sixty years old, had **typhoid fever** for three weeks. He had vomited all food taken for **forty-eight hours,** and was nervous and weak, and his physician had used every available means to relieve his uncontrollable emesis. In the hypnotic state I suggested that his nerves were getting quiet and steady and strong and repeated

this suggestion several times; that all nervousness or weakness was going away, that his stomach was getting stronger and stronger, easier and easier, and that by the time I counted ten all sickness or nausea or irritability or weakness about his stomach would be gone, and he could retain milk, liquid nourishment and water, and would enjoy them.

I also gave him suggestions to **give him a good night's sleep, etc.** We allowed him to sleep about twenty minutes, and upon waking him, allowed him to drink a glass of fresh buttermilk, which he retained and seemed to enjoy, remarking that that seemed to be the only thing that had tasted right to him since he had been sick. He continued to take milk or some form of liquid nourishment, and was not troubled further with sick stomach. He slept well at night and made a safe recovery. This book is written with a handsome fountain pen presented by that gentleman's son, a prominent jeweler of his city, who said, "When you use it, remember we feel grateful and consider that you saved father's life."

I recall several cases in which well known physicians have relieved persistent, incontrollable vomiting by hypnotic suggestion. There is more or less **neurotic** or **hysterical** or **neurasthenic element in all acute diseases,** which can and should be controlled by suggestion, with or without hypnotism, whichever seems indicated. In **pneumonia, typhoid** and **malarial fevers, the acute infectious diseases,** etc., in fact, **in any case** that comes into the hands of the physician or surgeon, the **psychic factor should never be overlooked.**

ILLUSTRATION NO. 6.

Psycho-neurotic Indigestion.—Indigestion is always accompanied by a neurotic element, with insomnia, nervousness, etc. In numerous instances I have relieved these cases of all distressing symptoms by a single treatment. In general suggestions should be given to **quiet off the nervous element** in the case, to give more plentiful and refreshing sleep, to get them to eat, drink and breathe, and exercise properly, as well as to encourage function. As seeing someone **sucking a juicy lemon** will increase the salivary secretion, so will sense impressions increase the functions of the stomach or any other involuntary function.

A young man, age twenty-four, had a "stricture of the oesophagus" for over two years. He had lived all the while on milk and soup, etc., taking no solid food during this time. **He had an enormously dilated stomach,** due to the large quantities of milk he had ingested. He had been treated as an invalid during the **entire two years or more,** and this itself was a constant suggestive influence to keep up his peculiar psychic condition.

The day I treated this young man, his physician, a most capable and excellent gentleman, had invited two consultants in view of deciding the advisability of making **an exploratory incision to find out the cause of the supposed oesophageal stricture.** I happened to be honored by an invitation to express an opinion in the case, and in a few minutes after I had the liberty of dealing with the young man, I had him eating bananas and drinking water as rapidly as anyone. **A few minutes devoted to hypnotic suggestion** was all that was necessary. After waking him, I advised a diet of eggs, bread and butter and vegetables, with meat

once a day, and suggested that the young man be put to work. When heard from two weeks later, he was hard at work and eating anything except milk and soup upon which he had been nourished for the past two years.

ILLUSTRATION NO. 7.

Another Psycho-neurotic Condition.—A lady about forty-two years old had been in the John Hopkins Hospital for several months and also had been treated in Southern sanitariums. Several operations, **mostly of a gynecological character,** had been performed. The nervous element in her case, for which she had been operated upon, **was only aggravated** after her return home, and for over two years she had occasional paroxysms of headache, indigestion, hysteria, insomnia, etc. Her physician explained that it usually took **about two days for him to get her relieved,** and then two days longer to get her over the effects of the therapeutic remedies he had used to relieve her terrible seizures.

She was hypnotized and allowed to sleep two hours and suggestions were given to relieve the nervous element in her case, to give her more plentiful and refreshing sleep, to relieve her headaches, to get her to breathe deeper, drink water freely, and aid her digestion. It was also suggested that her nerves would always be quiet and steady and strong and that she would never have another attack. She awoke from the two hours' sleep completely relieved. Five years later she had experienced no more trouble.

ILLUSTRATION NO. 8.

Obstetric Anaesthesia.—N. E., age twenty-two, primapara. Called at 9 a. m. and found patient with light pains and os open the size of a twenty-five cent piece. Hypnotic state induced and suggestion given that when I came to see her again when labor was well established that she would close her eyes and go to sleep and feel no pain. At 10 p. m. I was called and when I told her to close her eyes and go to sleep, and made other suggestions to get her into a deep state of suggestibility, **she easily went into the hypnotic state** and was completley amenable to suggestion.

She would extend her hands to receive help from an assistant and bore down with every contraction, but her expression showed no evidence of pain. **She did not get nervous** and **did not know when the child emerged** until I told her to wake up and look and see her baby.

ILLUSTRATION NO. 9.

Nocturnal Enuresis.—A little factory girl, sixteen years old, arose at 5 a. m. and returned home at 7 p. m. She was about the size of an average child of eleven, had been to school but two or three months in her life and the enuresis had been constant for over two years, but she found no trouble in holding her urine in daytime when awake.

I had a talk face to face with her father and mother, in which I made every effort to burn into their consciousness the enormity of the crime that they were committing in selling their child's brain and blood and muscles for a price. Then I explained kindly to them the importance **of air** and **sunshine and outdoor**

exercise and wholesome food. I should like to have had the owners of that factory take their part of the medicine, and the State authorities also, for permitting such a crime to be inflicted upon children. After this private lecture to the child's parents, I then induced hypnosis in the child and suggested that she would take **exercise night and morning and breathe deeply** and **that she could never urinate lying down again,** that the urine just would not come, her bladder would not let it pass until she got up to use the vessel. I also gave suggestion to relieve the nervous element in her case.

Quite frequently I have had **one single treatment** relieve a case of bedwetting, by suggestion in the hypnotic state. This little girl was heard from several days afterwards and had had no further trouble.

In a number of instances I have instructed the parents to **rock their children from two to six years old to sleep,** and to suggest to them, while going into a natural sleep, that they would wake up and call them when they desired to urinate, that they positively could not wet the bed any more, that without thinking about it they would call their parents or get out of bed on their own accord and use a vessel. In a number of cases the result of this treatment has been highly satisfactory.

ILLUSTRATION NO. 10.

A Retroverted Uterus and its Accompanying Neuroses.—"Good morning, what seems to be the trouble," said I to a negro girl about thirty years old.

"Got de fallin' of the womb, doctor."

"**How do you know** that is your trouble?"

"Doctor Blank said that was what was the matter with me."

"I see; how long has Doctor Blank been treating you?"

"Off and on for five months, doctor."

"And what has he done to relieve your womb trouble?"

"Put some medicine in my womb on an instrument with some cotton on it and put some cotton rolls to hold my womb up, and gave me medicine to take every three hours."

"Do you ever use a hot douche, use hot water with a syringe?"

"Yes, sir; I use that laying on my back for fifteen minutes twice a week."

On examination I found a decidedly retroflexed and retroverted uterus, bound down by adhesions, with heat, pain and tenderness, and her general temperature was 100.5° F.

"Have you been able to work any at all for the past several months?"

"Powerful little, doctor. I tries to do the cooking for a small family and only cooks two meals a day, but I gets awful tremily and weak and I don't sleep at night."

This woman was neurasthenic, suffering with insomina, but little appetite and poor digestion, anaemic and improperly nourished.

She needed her time to make a living; to give her scientific gynecological and surgical treatment was out of the question, for the facilities were not at hand in that locality to care for such patients. I attempted to lift the uterus from out of its impacted position, having put the patient in the knee chest position and applied a Hodge-Smith pessary to hold it. **Yes, I displayed bad judgment** by attempting to use a pessary in that

case, but the woman needed help and this was a step toward giving her a little more permanent relief than the continued use of the tampon. My effort to correct the displacement and introduce a pessary gave her much pain, and caused her to be extremely nervous, whereupon I hypnotized her and she went into a profound state of suggestibility.

Here was an ignorant colored woman and my suggestions to her were about as follows:

"Now, Mary, you are sound asleep. Sleep on quietly and get the benefit of this treatment. As you lie here (stroking her forehead) your nerves are getting steady and quiet and strong all over. All nervousness and weakness is going away and your nerves are getting steady and quiet and strong all over. By the time I count ten, your nerves will be steady and quiet and strong from your head clear down to your feet. One, two, three, four, five, six, seven, eight, nine, ten, and your nerves are steady and quiet and strong. You are perfectly easy and comfortable all over.

"Now, as you lie here and as I stroke your abdomen, you feel all pain or soreness or tenderness or congestion about your womb and ovaries going away. The blood vessels that carry blood to your womb are drying up and shrinking up, getting smaller and smaller. After this, every minute and every hour and every day you will become stronger and stronger, the blood will circulate freely in your stomach and you will be hungry and enjoy eating and your food will be digested and you will get stronger and stronger every day. You will drink water freely, a glass full at least every two hours. Your kidneys and liver

and bowels will act freely. Your bowels will move every morning after breakfast. Whether you feel like it or not you will go to the toilet after breakfast and your bowels will move freely.

"You will have no more pain; be easy, sleep well, enjoy eating and improve in health every day. Whenever you think of yourself, you will find that you are getting better, growing stronger, that you are perfectly easy and you will not be troubled any more."

Do you ask me if I had confidence in those suggestions to believe that they would be effective? I answer that question by saying that I had desire to benefit that poverty stricken unfortunate outcast sufficient for me to exercise the will to give the suggestions that I wanted to be effective. The confidence was all on her part. She had had faith enough in me to save the whole of the previous week's hard earned money and send it to me with a request that I come to see her, "please."

I awoke her from the treatment easily, with the parting suggestion, "you will get better every day now, Mary."

I fully intended calling to see her again after two or three days, but the pressure of my professional engagements for the following week caused me to forget her until about ten days afterward. Then I thought to myself I had treated her kindly and if she wanted me, I should have been notified.

Eleven and a half months after that visit, I received a call to another house in another portion of my town and found a colored girl suffering with malarial fever. As I removed the thermometer from her mouth, I remarked, "I have seen you before. **Where did I see you** and what was your trouble then?"

"You done forgot me, doctor? Nobody ever did do as much good for anyone as you did for me with that one visit you made me most a year ago."

Further questioning recalled to my memory that this was the girl whom I had hypnotized nearly a year before. I had often reproached myself for the unscientific procedure in attempting to use a pessary under such conditions and of my neglect of the case afterwards. I had supposed that she or some physician had removed the hard rubber pessary and that was the end of it so far as I was concerned.

"Why, girl, have you worn that instrument all the while and did not consult me about it? Don't you know that is liable to do you great injury?"

"Fo' God, doctor, I ain't had a speck of pain since you walked out of that house and I been doing my work regular up to yesterday."

On examination I found that the pessary was transversely across the vagina, with the uterus sharply retroflexed over it acting only as a foreign body, but that all congestion, soreness, tenderness, hyperplastic condition, etc., were gone. **A very careful examination proved** that there was no erosion or ulceration caused to the parts by the instrument, which had served to keep up a most unsanitary condition. Sexual intercourse, she informed me, had not been painful in the least, but on the other hand, was attended with normal gratification, when the act had been intolerable prior to my first visit.

I removed the pessary and gave her another treatment by hypnotic suggestion, suggesting to her that she would never

have the slightest pain or inconvenience from her womb, after that, since the instrument was removed. Her malarial fever rapidly yielded to treatment by calomel and quinine and when this woman was last seen, about two months afterward, she had experienced no more inconvenience.

After that experience, ten or twelve years ago, it fell to my lot to treat a great many gynecological cases, the majority of which, on account of poverty and lack of necessary facilities for radical surgical intervention, were treated conservatively.

I recall a number of cases among both whites and colored where I have relieved by hypnotic suggestions all the painful and nervous symptoms accompanying **a retro-displaced uterus.**

These poor unfortunate women, who did not have money to afford radical scientific surgical and gynecological assistance, were enabled to **meet all the exigencies of life** and be comfortable and happy, carrying a dislocated organ whose reproductive function was not a necessity to their happiness.

As showing the **far-reaching effect of hypnotic suggestion,** in a class of cases usually not considered amenable to benefit by psychological methods of treatment, I report the following three cases:

ILLUSTRATION NO. 11.

Urethritis with Bloody Micturition, Insomnia and Pain.—Lillie H., aged nineteen, married four months, last menstruation six weeks ago. Suffered with painful urethritis causing her to cry out when she voided her urine; passed blood from urethra or bladder when she urinated, which appeared in small clots and shreds in the vessel, suffered constant pain, for which she had

had a daily hypodermic of morphine for a period of one month. During this month she had taken the usual sedative diuretic remedies and the pain had constantly grown worse and the blood in the urine had gradually increased in amount. **The patient wore a distressed countenance,** had but little sleep, and when seen on August 8th, was seated on the bed crying and writhing her body from one side to the other, and was a picture of perfect misery and distress. **Examination of the womb found** it in normal position, a little enlarged, as would have been expected. Diagnosis, congestive urethritis due to reflex disturbance caused by impregnated uterus.

The hypnotic state was induced and proper suggestions were made for relief of pain and cure of all congestion in or about genito-urinary organs. (Note that this was my first visit after this condition had **lasted one month,** and she had constantly had the hypodermic of morphine all the while, thus complicating her case by making her a morphine habituate.)

Second visit eight hours later on the same day, found patient easy, but still discharging blood. **Would not permit treatment by suggestion,** as she begged for morphine. Did not sleep that night, as she had no suggestion to that effect and morphine had suddenly been withdrawn.

Next day she was placed in a deep hypnotic state, appropriate suggestions were given, and she was allowed to sleep four hours; awoke free from pain, and nerves quiet. Treatment by suggestion on same afternoon. Slept well that night, and after that she suffered no more inconvenience from either nervousness or pain. **At the end of one more day** all pain and bloody

discharges were gone, the patient was happy, strong, and with good appetite. Two days later the same, four weeks later the same.

ILLUSTRATION NO. 12.

Menorrhagia and Anaemia Accompanying Large Fibroid Tumor of Uterus.—Woman, forty-eight years of age; has large fibroid, profuse menorrhagia for fifteen weeks, greatly emaciated, anaemic, constipated and weak, pulse 140, respiration 60, temperature 102°F. Passing clots as large as a hen's egg and when seen was the picture of distress, with no appetite, very nervous and unable to sleep; suffering also with a remittent malarial fever.

Her case seemed to me to be one in which at best life could not be expected to last longer than a few days. Treatment—Calomel, followed by salines and 15 grains of quinine sulphate daily for the malarial element in her case. Deep hypnosis was induced at my first visit and proper suggestions were made to restore sleep and relieve nervousness, regulate her bowels, to stop hemorrhage, to aid digestion, to give appetite and to build up hope and to change her intuition or belief that she was going to die into belief that she would get well.

From the first treatment by suggestion her nerves were quiet, her sleep was refreshing and plentiful, her appetite was good, and her heart beats slower and stronger and breathing easier. **After four treatments by suggestion** the menorrhagia had entirely stopped. She was then put on a tonic. **Two years later** she was in good health, with her fibroid growing smaller.

ILLUSTRATION NO. 13.

A Unique Case.—A Patient fifteen years of age with acute gonorrhea and badly swollen prepuce, had not urinated in thirty-six hours. His bladder in lower part of abdomen felt like a large cocoanut. His pain and suffering were intense. The meatus had in it the large drop of characteristic yellow pus. He had used a hot water hip bath for the relief of his trouble, but without success. To use a catheter would mean to push the disease back into his bladder, giving him gonorrheal cystitis. **Hypnosis was induced** and suggestion made that when he awoke he could urinate freely.

On awakening he expressed the desire to urinate, "oh, so bad," and in one more minute a forcible but small stream began, lasting five minutes. I then gave him a prescription for his gonorrhea, and he went home happy and free from pain. Ten days later he was seen and the case was progressing nicely.

ILLUSTRATION NO. 14.

Another Unique Case.—A physician said to me upon one occasion, "Can you hypnotize this boy so that I can catheterize him." He had acute gonorrhea and was having a catheter used twice a day, in order to relieve his full bladder, which he was not able to relieve in the usual way. Hypnosis was induced and suggestion given to relieve the psycho-neurotic element, and when he awoke **he urinated without catheterization** and continued to do so thereafter.

ILLUSTRATION NO. 15.

Morphine Habit.—This was a patient of one of the **best known physicians in the south.** Her ovaries had been removed,

cervix and perineum repaired, but the operative procedures had only aggravated the neurotic symptoms that they were intended to relieve. In addition to the aggravated nervous symptoms, she had a pain in one side, which had appeared as a result of adhesions, and to relieve this the administration of morphine had been instituted and continued for several months or more. The pain had subsided, but the demand for the continued use of morphine was imperative, at least from this lady's point of view. Five or six months had elapsed since the beginning of the habit, which was now well fixed.

The patient lived forty miles distant and was ordered to come into the city. Her physician explained to her that I had a treatment which would relieve her of the morphine habit without inconvenience, and both she and her husband consented to co-operate with our plans. She was given at a dose for four doses every two hours, beginning at 2 p. m.

℞Calomel, 1 grain.
Resinous podophyllin, 1-8 grain,
Extract of nux vomica, 1-6 grain,
Powdered extract cascara sagrada, 1 grain,
Aloin, 1-5 grain.
M. et. ft. caps. No. 1.

This dose was given in a capsule, every two hours for four doses, beginning at 2 p. m., and the patient was allowed to have her usual hypodermic of one grain of morphine that evening.

The following morning she was given two drachms of Rochelle salts every hour until copious watery evacuations were

produced, and this was directed to be given without regard to the action of the purgative dose administered the previous day.

Thorough elimination of the **by-products of morphine** must be secured as well as the getting rid of all retained excreta due to the continued use of morphine. At 11 a. m. the next day a warm bath was ordered, warm enough to secure thorough relaxation, and the drinking of copious draughts of water was also insisted upon for eliminative purposes.

No more morphine was allowed after the dose the day previous. When thorough elimination is secured in this way, morphine can be abruptly withdrawn without any inconvenience to the heart's action; in fact, the patient is less apt to die without the morphine than with it, provided the nervous element in the case is cared for, and this can be controlled by suggestion.

At noon on the second day, after copious actions of the purgative given the day previous and a saline had been given, and a warm bath had been administered, the patient was hypnotized and allowed to sleep for three hours. **It was suggested that her** nerves were steady and quiet and strong, and that her heart would beat strong and regular; that every minute and hour after that her nerves would get steadier and quieter and stronger; that she would enjoy her meals, feel hopeful, optimistic, and cheerful, and after that would have an antipathy for morphine or any form of opium; that she would breathe deeply, drink water freely and take an interest in the affairs of life as she had not done in many months. **It was suggested that at bedtime** she would take three drops of the placebo prescription and go sound

asleep and sleep soundly all night and awaken every morning feeling refreshed and well rested.

After three hours' sleep she was awakened and ate a lunch of milk, bread and butter and at once took the train for home, forty miles away. **Five days afterward** I went to this lady's home town, where her husband had gotten the physicians interested in my class work, and instructed a class of physicians at that place, allowing the husband of the patient to be present. She was then sleeping, eating and doing well in every way.

Twenty-seven days after the withdrawal of the morphine, in response to a letter of inquiry I learned that the patient had experienced no more inconvenience, had slept well, enjoyed eating, gained in weight, and was happier and better in every way. "But," said he, "yesterday my wife overexerted herself and I used a hypodermic of one-fourth of a grain of morphine last night, the first that she had taken in twenty-seven days." The only thing left for me to do was to write to him and express my regret that he had acted so unwisely and urged him to use reason, castor oil, Epsom salts, hot poultices, bromides, or do anything else but to deliberately start her on morphine with an already acquired predisposition for the drug.

To educate an individual in the principles of psycho-therapy is one thing, but to get them to exercise the force of character sufficient to apply these principles is something else.

ILLUSTRATION NO. 16.

Chronic Indigestion.—A country editor, age thirty-four, had for several years suffered from indigestion, and in two years he had not eaten meat for supper without spending a restless night

and having little sleep, followed by no appetite and a bad headache the next day.

He was hypnotized and suggestions were given to encourage a freer flow of blood in his stomach, **to stimulate the cerebral centers that influence this important organ** and also to quiet the nervous element in his case, get him to breathe deeper, and drink more water. Upon awakening him, I advised that he eat some of everything upon the table at his boarding place that evening. "But suppose it makes me sick," asked he. "Then I will pay your doctor's bill," was my reply. "Suppose it kills me?" "I'll buy your coffin and pay your burial expenses," was my answer.

Then addressing him, I said, "Mr. Blank, go and eat as much of everything you have on your table as you desire and especially eat meat, and come tomorrow and tell me how you are feeling." The next day he returned and said he had eaten a hearty supper of pork sausage and broiled beefsteak and never had a better night's sleep or felt better in his life. I laughed and in a friendly way advised him to eat as much of everything as he wished in the future **except printing presses and newspaper editors.** Several days afterwards he was cheerful and happy and had experienced no more difficulty.

It is interesting to me to see the skilled laboratory chemical analysis of the gastric contents, made by some of our physicians, and the diet and medication prescribed according to indications in the light of the teachings of modern physiology. **It is beautiful work, requires great skill,** and proceeds upon exact scientific basis, and I hope some day to be equipped to do such work myself in order more scientifically to report the results of psycho-

logical methods of treatment, but my confidence in the brain plasm and its influence over the physiological processes is such that these methods in the large majority of cases seem to me to be quite unnecessary.

In gross pathological changes, however, due to destructive processes, malignant stomach affections, etc., there is presented quite another aspect of the subject, and these methods throw a wonderful light upon the case at hand. However, we must be careful not to **fasten upon our patient by the unconscious use of suggestion a psycho-pathological condition** instead of relieving him of a psycho-neurotic disturbance.

ILLUSTRATION NO. 17.

Subacute Sciatica.—A man aged forty-five was confined to his bed with acute sciatica for several weeks and for five or six months following had used crutches, unable to bear his weight on the affected side. His physician had invited some of his professional friends to witness the treatment of this case.

The history of the case, the time that had elapsed, the rational therapeutic measures, etc., that had been employed, together with the symptoms at hand, convinced me that the severe pain, insomnia, and functional disturbances were unduly **aggravated by the prolonged attention** that had been given to them by the patient, which had **created sense impressions** that **reproduced themselves in the peculiar mental state** exhibited by him.

There is always a tendency for the nervous system to **retain an impression after the cause which gave it birth has passed away.** This proved to be true in this case of sciatica. The pa-

tient was hypnotized and suggestions were given to relieve his pain, to quiet nervousness, restore sleep and re-establish the function of the disabled limb. **The man while in the hypnotic state was persuaded** to use the limb, and when awakened stamped his foot on the floor, walked, jumped, hopped on the affected limb, and then turned in all seriousness to the physician and said he was easy for the first time in five months. After seeing him three more times on each of the following days successively, he went to his work. This man was a carpenter and appeared in no sense to belong to the hysterical type, yet this was a psycho-neurotic condition.

ILLUSTRATION NO. 18.

Bronchitis, Asthma, Pneumonia, Etc.—A man, fifty years old, had had chronic bronchitis for fifteen years, with occasional paroxysms of asthma. He now had acute pneumonia, affecting the lower lobe of the right lung only, but had a temperature of 104.5°F., pulse 135, and rapid respiration also. On the fifth day of his acute illness he had slept but little the previous three nights and was extremely nervous and over-solicitous about his condition. There was a large element of fear about his case, which gave rise to very bad auto-suggestions. These were encouraged by an over-anxious family and friends. I had done all within my power to re-assure him by suggestion without hypnotism but to no avail.

Seeing his anxiety so pronounced and the psychic element in his case so adverse to his recovery, I decided that one more day without a change would mean the death of my patient. Taking in my hand a bottle of some placebo, I said to him earnestly,

"Mr. Blank, there is a nervous element in your case that I am going to relieve before I leave you. This medicine, used as I am going to use it presently, will put you to sleep, quiet your nerves, strengthen your heart and help you to get well. Now, it can't hurt you, but will make you stronger. I will stay with you until you awaken, and you will be feeling better and stronger and take quite a different view of your condition when you awake."

A patient in that condition is always easy to hypnotize. **This man readily consented to the treatment,** and while in the hypnotic state I suggested to him that all nervousness was going away and that his nerves were getting steady and quiet and strong. Then I also suggested that his heart was beating stronger and stronger, and that his hands and feet were getting warm, that the blood was circulating freely all over his body, that all congestion and pain about his lungs were going away, and that his fever was cooling, temperature getting more normal, and nerves and muscles and heart getting quiet and steady and strong. I suggested that every dose of the medicine he was taking would quiet his nerves, strengthen his heart, lessen his fever, aid his digestion, and that whenever he thought of himself he would feel that he was getting better, feeling stronger, and going rapidly on to recovery. I allowed him to sleep for twenty miniutes or half an hour. When I awoke him I gave him the answer to my question, which was more an affirmation than a question. **"You are feeling better, Mr. Blank?** This has done you a great deal of good." "Yes, doctor," said, he **"I feel that I am going to get well and have not felt that way before."**

I then took his temperature and found it two degrees lower than it was thirty minutes previously, and his pulse beats twenty a minute fewer than before he went to sleep.

He slept well that night, as I suggested he would, and his pulse and temperature were better the next day. His temperature never went any higher than 102.5°F. after that or his pulse above 120 a minute. His lungs cleared up on the ninth day.

Two years afterwards, that man had not had another attack of asthma, as I had suggested on two or three occasions following the first treatment by hypnotic suggestion that he would never have asthma again, that he would always drink plenty of water, the bowels would move regularly every day, and he would sleep soundly, have a good digestion, and always feel better.

It may be pointed out that in asthma there are always functional disturbances due to deficient elimination causing a general neurotic condition, of which the asthmatic paroxysm is the predominant manifestation, and attracts the greatest attention.

In regard to the use of hypnotism in very sick people suffering with pneumonia and enteric fever, the acute infectious diseases, etc., I have always felt that if I could get the patient to exercise enough self-control to go into the hypnotic state he would be certain to recover. **No possible harm can come from giving a patient suggestions to quiet nervousness,** relieve pain, re-establish function, and encourage the action of all the brain centers, turning this energy represented by the cells that compose the cerebral cortex to the strengthening of every cell and every function in the body.

Hypnotism is only an intensified, and therefore more efficacious form of applying suggestion and it seems to relieve a very sick patient of a heavy responsibility, when you use his psychic powers for him, direct them, and regulate their control over his body rather than keep him on the alert to do this for himself.

There are yet some physicians who believe that suggestion is of value only in hysterical subjects and that only hysterical people can be benefitted. If that be true, **then all sick people are hysterical,** for there is no acute febrile illness in which the psychic factor does not play an important role in helping or hindering the recovery of the patient.

Remember that there is such a thing as nervous shock, due to sense impressions which give rise to fear thoughts that hold the attention of a very sick patient. The physician who can **change these psychic states,** changes the mental attitude of his patient, encourages all involuntary physiological processes, **and helps his patient to recovery.**

It is **hard to hypnotize an hysterical patient,** while, on the other hand, **a normal nervous organization always best responds to suggestion** and makes the best hypnotic subject. This I have demonstrated and proved to the satisfaction of **several thousand American physicians,** notwithstanding the opinion of a few prejudiced neurologists, who are self-hypnotized by their preconceived convictions, to the contrary.

ILLUSTRATION NO. 19.

Dressing a Painful Wound.—A gentleman, thirty-two years old, had his foot infected with a gas-producing germ which caused the leg to swell enormously. To give him the only chance to

recover the surgeon amputated the limb at a point about seven inches below the hip joint and dressed the amputation wide open, not allowing the flaps to close, in order to secure thorough drainage. **Large quantities** of gauze came away at each dressing literally soaked in purulent discharge, as the infection had extended above the amputation.

The patient's reserve forces were being drawn upon heavily and his toxic condition left him unable to withstand pain. He did not appear hysterical, but at each dressing of the wound he could be heard crying all over the hospital, on account of the severe pain. He was placed in a suggestible condition, using a placebo medicine as an aid, suggestions were given to produce anaesthesia, and the wound was dressed without the slightest complaint on the part of patient.

ILLUSTRATION NO. 20.

Hysteria, Neurasthenia with Delusions, Hallucinations, Etc. —A delicate, high-strung, nervous young woman, with ambition while in college three times in excess of her physical strength. A decidedly neurotic tendency, always over-sensitive and morbidly conscientious. This condition had been encouraged by overstrain in education and by one incident after another which proved to be a shock too great for a nervous system so unstable; yet not more than a normal individual could easily withstand. **Finally came an attack of typhoid fever,** and when the patient was seen several months later she had for five months been confined to her room with hands and arms fastened, **with delusions of persecution,** and impersonating one character after another sent down to earth by Prometheus, etc.

She drank but little water, taking only a small quantity of milk for nourishment; her bowels moved **only under influence of purgatives;** there was **constant enuresis,** sleep was secured only by hypnotics, bromides, etc. **She had a furred tongue, fetid breath, rapid pulse,** was extremely nervous, with an excitable, over-active brain, and finally would become exhausted and lie with head hot and bathed all over in perspiration. At my first visit I released her arms and **acted as if I had perfect confidence in her,** had her exercise every muscle, breathe deeply, drink one glass of water, and after an hour another glass. I then put her into **a light state of hypnosis** and gave suggestions to **quiet nervousness,** to relieve an **over-excitable brain, secure sleep, cure enuresis, correct delusions, create appetite and thirst, and to regulate bowels, etc.**

Besides releasing her from the fastenings on her arms, **all medicine was withdrawn at once** save a one-eighth grain dose of protoiodide of mercury, which was ordered to be given at bed time for its general tonic effect. **From the first treatment by hypnotic suggestion** she became quiet, slept well at night, ate three wholesome meals a day, had but few delusions, enuresis was stopped, pulse quiet and normal, talk rational, and the whole picture of the case was changed.

After one week she was eating, sleeping, drinking water freely, exercising and resting alternately, practicing deep breathing, and presented every indication of great improvement, while previously she had been gradually growing worse for several months and probably several years. **After two weeks' treatment,** she made up her own bed, swept her own room, took walks

in the park, and assisted in the housework, busying herself with fancy work, etc.

The outcome of this case is for time only to decide. **The permanency of the results obtained by suggestive therapeutics depends altogether upon the stability of the nervous system.** A favorable out come in a case like this will depend upon our ability to bring about those conditions **necessary to physical development,** sleep, food, drink, exercise, mental quietude, as well as directing her habits of thought and action into healthful, normal channels. Yet, **the results so far** show the possiblities for help even in this unfortunate class of cases.

Sanity or insanity is not to be ascertained by any definite standard. They are terms that cannot be defined, for one merely denotes the absence of the other. They are both only relative terms. It is absolutely impossible to find a person of so healthy a mind and body that some form of degeneracy cannot be observed. As a well-known psychologist remarked, **"No one can be accused of being hopelessly sane."** Yet, if an individual is **unable to look after his affairs and is dangerous to himself and others,** and interferes with society, he may undoubtedly be said to be of unsound mind. At any rate, insanity is not revealed by any one symptom. The change is displayed by everything both physical and mental. The degeneration **affects the body as a whole.**

Not every person that is sick, then, should be counted as insane, for all disease affects both mind and body in a degree. **There are many people that are insane,** however, who, had timely treatment been instituted, could have been completely restored

to a normal condition of health in both mind and body. "Treatment," in the sense used in the above remark involves education environment, dietetics, exercise or employment, and all that contributes to the evolution of the individual.

Suggestions, both with and without hypnotism, in the hands of a thoughtful physician can do much toward bringing about those conditions under which recovery may be rendered possible.

Hypnotic Suggestion in Surgery.

One physician who had taken my personal instruction in suggestive therapeutics informed me six months afterwards that he had used hypnotic suggestion for anaesthesia in not less than five or six hundred cases of minor surgery with complete success. Another stated that he used suggestion both with and without hypnotism, in obstetrics and minor surgery so frequently that it had become an unconscious habit with him. All physicians use suggestion, consciously or unconsciously. Only those who have studied and understand the use of hypnotism use it systematically and scientifically, so as to get the most efficacious results from its employment.

An anaesthetist who understands the systematic and artful use of suggestion will, in some cases, use not over one-fourth of the amount of chloroform or ether that would be required by another, who does not properly use suggestion, and will thus greatly lessen the danger of anaesthetics. In giving chloroform, or ether, engage the attention of your patient. This should be done tactfully, so as to gain his spontaneous attention without letting him know that you are making an effort to impress him. Examine his heart and pulse and affirm: "You are in fine con-

dition to take an anaesthetic; now, I want you to do as I request and this will put you in a sound sleep without the slightest danger. Given by the method that I use, it only makes your circulation and breathing strong and regular, while all other functions are inhibited. Now, close your eyes lightly, breathe through your mouth, and think of going to sleep. As you inhale this remedy, you will get quiet all over and get drowsy and sleepy and go to sleep and awake after the operation feeling fine. **You will not be sick at your stomach** or nauseated in the least degree. We are going to take good care of you and you will get along all right. Now, breathe this down and go to sleep, sleep, sleep, sleep," etc.

I employ the same suggestions as are used to induce hypnosis, and at the same time use chloroform or ether, only to the minimum extent required.

If you expect to push the chloroform or ether to the extent that sense impressions could not be made on the brain or suggestions be presented to your patient, suggest to him before he is fully under the anaesthetic that he will be perfectly relaxed and limber, that he will breathe deeply and regularly, that his heart will beat strongly and regularly, and that he will have no feeling, that all sensation will disappear. Then proceed with the anaesthetic.

Frequently, however, **I start off with ten or twenty drops of chloroform** and hypnotize the patient while he thinks the anaesthetic is producing the result. In that case I suggest to the patient, after hypnosis is induced, that all feeling, all sensation in the field of operation, is going away, that the part is becoming

perfectly dead, and that by the time I count ten the part will have no feeling in it.

ILLUSTRATION NO. 21.

Suprapubic Cystotomy.—The operation was decided on, the patient being a man about forty years of age, who had an infection produced by a catheter being thrust through the urethra, behind the bladder into the peritoneal cavity, an abscess being formed, extending above and in front of the bladder. **It was the "other fellow's patient,"** and I had been invited to go with the consulting surgeon to see what could be done for the unfortunate. The surgeon said to the sick man, **already in a subconscious condition,** due to his anxiety over his serious case, "This is a physician friend of mine and he will give you chloroform and put you to sleep and we will do the right thing for you. Do just as he tells you and he will take good care of you."

With a piece of gauze on the bottom of my hand and with ten drops of chloroform on it, I said to the patient, **"Close your eyes, breathe through your mouth, and think of going to sleep.** As you inhale this chloroform, you will get drowsy and sleepy and go on to sleep without any trouble." I then exercised suggestion on him, using the formula described in a previous chapter to induce hypnosis. (Hypnotism demonstrated.)

With a piece of cotton saturated with water, after the patient was hypnotized, I gently touched the area to be operated on, saying to him, "All feeling is going away; this part is becoming perfectly dead, no feeling in it at all, and by the time I count ten it will be perfectly dead and without feeling."

In the midst of the operation the surgeon asked, "How much

of this is suggestion and how much is chloroform?" I answered him by holding the man's arm up and suggesting that he allow it to remain until the operation was completed. We afterwards awoke the patient with nerves steady and quiet and strong, as suggested to him, and he stated that he had experienced no pain and felt much better. In this case we used not over twenty drops of chloroform by actual measurement.

Always tell your patient how he will feel before waking him. That will determine his feeling after he is hypnotized. It is **not only what you do** and what you say that brings success, but the **way you do and how you say it.** This is true of the use of suggestion both with and without hypnotism.

In reducing dislocations, setting fractures, opening abscesses, sewing up incised wounds, and numerous other conditions, hypnotic suggestion is applicable. Yet, so much depends upon the environment, for an adverse environment produces a counter influence by unconscious suggestion, that it is often impossible to overcome. **In private practice,** however, we have an ideal condition for the application of suggestive therapeutics. It is here that the best results are always obtained, for there is a closer personal relation between the physician and his patient.

ILLUSTRATION NO. 22.

Operation for Adenoids.—This patient was **a little girl ten years old,** with adenoids to be removed. She was hypnotized, and the suggestion given that when the doctor examined in her mouth and back of her throat and nose, it would only tickle her a little, that the parts back there were dead, had no feeling in them, and that when I said "Wake," she would awake laughing

and see some blood come out of her nose and mouth. The operation was done by a well-known specialist, and with perfect success. The little girl did not shed a tear.

ILLUSTRATION NO. 23.

Suggestion in Dental Surgery.—A young man twenty-four years of age, by occupation a drug clerk, had serious valvular lesions, and cocaine or chloroform or ether was positively forbidden by his physician. **At his request** I hypnotized him in the presence of three well-known physicians and surgeons, and two large molar teeth were extracted without pain, and he was less nervous after the operation than before he took his seat in the chair. Two of the physicians examined the heart before and after the operation and remarked upon the improved nervous condition. After inducing hypnosis, I suggested that he open his mouth, and then applying a small quantity of an antiseptic solution upon some cotton around his tooth, suggested that all feeling was going away, that his gum and tooth and jaw were becoming perfectly dead, and that by the time I counted five, that entire side of his face **would have no feeling in it,** that the dentist could extract the tooth, without the patient's feeling any pain.

To use hypnotism or suggestion with success in surgery or dentistry, you must have the confidence of your patient. In fact, the best results from suggestive therapeutics **in all classes of practice can be obtained only** where a perfect confidential relation exists between the patient and the attending physician. **For that reason,** suggestive therapeutics will never be particularly applicable to general hospital work, but in private sanita-

rium work, where the physician is brought into close relation to his patient, an ideal condition is presented.

ILLUSTRATION NO. 24.

Psychical Impotency.—A young man had been accused by a jealous wife of worshiping a foreign goddess. This he strenuously denied. However, upon one occassion he walked by his home with the lady in question and was observed by his suspecting wife. Though he assured her that his being with her upon the occasion was only a coincidence, his assurances did not allay his wife's suspicions, and she then and there demanded that he prove his fidelity by his ability to perform the sexual act. Though the young man was innocent, the psychic effect of being put to so crucial a test, so suddenly, was sufficient to completely inhibit his ability to meet the demands. **Then the exacting wife turned** with double vehemence upon the unfortunate husband, and the sense impressions or suggestions produced by her declarations that she had proof positive of the correctness of her suspicions, rendered the poor fellow impotent, in her presence, for a month.

The stability of his home was in jeopardy, and threats of abandonment were made by the wife, who felt that she had been wronged. His physician sent for me and my treatment for the young man was by **instruction and education** as to how he should steer himself out of his dilemma. **He was also hypnotized** and special suggestions were given to combat the psychic effect of the suggestions that had so completely subdued him. This was on Saturday, and on Monday he reported that the psychic

atmosphere of his home had been completely changed and that the treatment was a decided success.

The psychology of the sexual relation is a most interesting and important subject, and involves the consideration of the physical, emotional, intellectual, ethical, aesthetic and moral qualities of human beings. It is related to every phase of life—educational, religious, social and moral — and plays an all-important part in the production of health and happiness. **The highest function of the physician** is to be prepared to give sane, wholesome, sensible advice where needed in such cases, and to save such as are seeking help from the vampires who live and thrive upon the distorted imaginations, credulity and suggestibility of those who are honestly and earnestly seeking relief.

ILLUSTRATION NO. 25.

Insomnia Treated in a Unique Manner.—" Doctor, I wish you would give me something to make me sleep better at night," said the wife of a hard-working man upon whom the cares of life were pressing heavily.

" Why can't you sleep, Mrs. Blank ? " said I.

" Oh, I just toss and roll about for hours and hours, and last night I didn't close my eyes until after one o'clock."

This lady was a great religious character, and I knew this was her most vulnerable point from a psychological stand-point; so I asked her if she believed that if two people agreed as touching any one thing it could be done for them. " You know I do, doctor," she answered.

" All right," said I. " Let's agree that you are going to go to sleep right now." I was standing at the foot of her bed,

and, looking into her face for a moment, I said in a calm monotone voice: **" Just look at me and think of sleep.** As you do, your eyes will become heavy and you will get drowsy and sleepy and go to sleep. Now, close your eyes lightly and go to sleep, sleep, sleep, sleep. By the time I count ten you will be fast asleep, one, two, three, four, five, six, seven, eight, nine, ten and now you are asleep, fast asleep."

Then coming up to her I gently soothed her forehead with a few strokes on either side with my fingers. " You are sleeping nicely, having a calm, refreshing sleep. Sleep soundly for two hours and then awake. Your sleep will be restful and refreshing. After this you will be able to go to sleep at any time you desire to do so. Just close your eyes and relax every muscle and think of sleep, and you will go to sleep and sleep soundly all night, and awake feeling refreshed and rested every morning. **You will drink water freely** every two hours from morning until you retire at night. You will enjoy your meals, have a good appetite, find pleasure in your work, rest when you get tired enjoy the companionship of your husband and children and friends, and always feel happier on account of the improved condition of your health."

Two years afterwards this woman's husband reminded me of this experience. He said his wife had slept well and enjoyed her meals, had no more headaches and was greatly improved in every way. **" Nothing ever did her so much good,** doctor, as that one visit of yours, but we lost our baby with cholera infantum two months ago and my wife is 'just all in,' and I want you to see her again." This was on a passing visit to my home

and I could not see his wife as requested, but I have always felt that I missed a great pleasure in not having the opportunity to infuse into her sad life some of my own strength and optimism by another suggestive treatment.

ILLUSTRATION NO. 26.

A Psycho-neurotic Condition.—A young lady twenty-two years old, the beautiful daughter of a prominent physician, had not been able to eat any meat without it causing gastric disturbance, since the death of her mother two years before, and since that time she had been nervous, suffered with insomnia, and lost considerably in weight. I gave her two suggestive treatments, having first secured a suggestible condition. **Two weeks later she reported her case,** and had gained in weight, slept well at night, ate all the meat she desired without the slightest inconvenience, and felt better and happier in every way.

ILLUSTRATION NO. 27.

Nausea and Vomiting of Pregnancy.—A Physician once stated to me frankly that he had no confidence in anything pertaining to these methods and could not possibly become interested in a subject that he had so disregarded. **He was an excellent gentleman,** but like so many physicians in our profession, had not troubled himself to look into the subject of psychotherapy.

A day or two later he said to a patient of his, the wife of a leading banker in his city, who had suffered with gravid nausea persistently for several days, "If you don't get better, I will bring a physician here who will treat you by hypnotic suggestion."

Her mother, who was present, urged that he do so, and referred to a physician who had relieved her brother, the Reverend Blank, D. D., a prominent educator, of a most distressing supra-orbital neuralgia, after no benefit had been obtained from other methods of treatment for over two weeks. **His patient also urged** that I be called in to see her. In his conveyance, while on our way to see this patient, I asked why he desired to use a a method in which he **"had absolutely no confidence,"** and had so expressed himself only two days before, wherein he related to me the circumstance just referred to.

"For this visit she is my patient as well as she is yours, doctor," said I, "and I expeet to get a fine result."

The preconceived mental attitude of your patient is of great psychic significance in determining the results of any kind of therapeutic measures. I had this lady's confidence before I ever saw her, and this was an ideal relation.

After talking with her for a few minutes, I turned to her and said I was glad to have the opportunity of demonstrating to Doctor Blank the efficacy of the method of treatment which I was introducing to physicians, and in this particular case it would be a genuine pleasure for her sake, as well as for my own and Doctor Blank's.

I had that lady hypnotized or in a suggestible condition before I suggested that she go to sleep, yet I placed her in a deep subconscious or hypnotic condition and made appropriate suggestions.

She was allowed to sleep twenty minutes, and awoke comfortable, ate some bread and buttermilk, as I suggested, and as

she drank it down, stopped to ask her mother if she remembered that she went to the refrigerator upon her return from her graduating exercises four years before, and remarked that no milk had ever tasted so nice before or since until she got this glass, and she proceeded to drain its contents. **Her comments upon that glass of buttermilk** reminded me of how I relished nice buttermilk when a boy on the farm, and I asked for a glass and drank to her health, and it was fine, too. I hypnotized my patient, but got hypnotized myself into drinking a glass of milk before I left the room.

That lady ate her evening meal, slept well that night, enjoyed her breakfast and was out driving the next day. A year later her mother reported to me that **she went for several weeks without inconvenience,** but after that, the destruction of some choice flowers by a stupid gardener brought on the return of her trouble, but "it was never so bad."

ILLUSTRATION NO. 28.

Supraorbital Neuralgia.—The case of the prominent educator mentioned in illustration No. 27, who had supraorbital neuralgia, was an interesting one, and is worth relating here, as it brings out some important features in connection with the application of suggestive therapeutics, and at the same time **clears up some misapprehensions** in regard to hypnotism and its application to the higher grades of intelligence. **The gentleman in question** was the president of a well-known college in his State. When I met him he apologized for his "stupidity" and explained that his case had resisted all treatment for two weeks and was getting the best of him. He said that twenty-five grains of quinine

daily and two one-quarter grain doses of morphine sulphate had been his dose for the past several days, besides using static electricity, hot applications, different standard neuralgic remedies and all the modern "antis."

"Let me relieve you by suggestion, doctor," said I.

"What, do you mean to hypnotize me?" he replied, somewhat astonished.

"Yes, get you to take a suggestion."

"But I never thought I could be hypnotized," said he.

"Only weak minded persons cannot be hypnotized, cannot be induced to execute an idea or series of ideas, for the lack of ability to exercise self-control, and certainly one cannot hypnotize a strong minded person who does not care to be hypnotized. Of course, you belong to the latter class, but if you will consent, I will show you what can be done for you."

"My dear sir," replied he, "I will consent to anything that even holds out a hope of relief." We very promptly arranged to give him the treatment and I left him in a condition supposed to be sleep, having made appropriate suggestions.

Ten days later I saw him again, and he was quick to thank me for the very prompt and efficacious relief given him by the treatment, and said he had not suffered one iota from that condition since I left him, "But, doctor," said he, **"I don't think I was asleep.** I wanted to tell you that I was easy before you left, but promised to lie still in the condition as you requested!"

That was just where he consented to **act intelligently upon** and **execute an idea or take my suggestion. All that is necessary is the intelligent co-operation** of the patient; so I repeat again

for I desire to drive this point home, that hypnotism is nothing more or less than getting an individual **to act upon an idea or series of ideas, either consciously or subconsciously.**

Get out of your mind anything you ever saw on the stage in exhibition of the amusement features of hypnotism. Even there, however, you see an illustration of the subject under discussion. **Boys like fun.** It is in their line—in accordance with their thought and conduct—and they go on the stage having perhaps unconsciously decided **to act upon or execute any idea or series of ideas given by the hypnotist.** Your patient does the same thing when he co-operates with you in any ordinary method of treatment.

ILLUSTRATION NO. 29.

Alcoholism and its Accompanying Neuroses.—Once, in one of our great American cities, a well-known physician telephoned me to know what I could do with a case of acute alcoholism. I replied that I had good results in my private practice in such cases, but that it all depended upon the character of the individual.

He wanted me to come at once to treat a patient of his who had been drinking too freely for a week or more, had taken not less than fifteen drinks that day, but was anxious to quit. **His patient was a fine man,** who proved afterwards to be one of the most delightful men I ever met, but he had his vulnerable point and his friends had led him too far.

If I can talk to an individual for a few minutes I feel the personality of the man sufficiently to approach him with a degree of certainty or with uncertainty as regards results. I suppose

this is acquired by experience. Anyway, I was not in this gentleman's presence five minutes before I said to his physician, " Doctor, we are going to get along all right. I am ready to proceed with the treatment." **The patient, a business man and capitalist,** about forty-eight years old, was nervous, emotional, irritable, miserable, and had suffered with insomnia, anorexia, etc., and just felt that something had to be done for him. **Even in the condition described,** the man was a gentleman, showed that he had a great soul in him, and I could feel that I had in him the elements of a man to use on his own behalf, which he, from inability to express the supreme function of consciousness, the will, had failed to use for himself.

I induced the suggestive state and allowed him to sleep for three hours, giving him a glass of water at intervals of an hour apart without arousing him from the existing state of suggestibility.

He was then awakened and advised to take a walk for half-an-hour or more with his wife, a bowl of chicken broth being ordered in the meantime. In the suggestive state I had made such suggestions as would quiet nervousness, relieve soreness in the epigastric region, restore self-confidence, produce an antipathy or hatred for whisky, and arouse the highest element of selfhood into action.

It was also suggested that after his walk he would eat a bowl of chicken broth and then go to bed and at once go sound asleep, that he would sleep soundly all night, and that if he became restless during the night, his wife would give him a glass of water and he would go sound asleep again. I impressed on him

that he **would not wake until nine o'clock the next day,** at which time his wife would awaken him. Then, as has been my custom, I told him he would feel rested, refreshed, self-sufficient, and not want whisky any more.

At eleven o'clock the next day his wife phoned me, in response to an inquiry about his condition, using these words: "Oh, doctor, he is doing beautifully. He slept all night long, taking water twice, and looks so calm and self poised this morning. **He says he does not want any more whisky,** and I never saw him look and talk like this after a spree before."

I saw him only twice more and talked to him face to face as friend with friend. Several weeks later, when I was ready to leave that city, he came to my room at the hotel, again expressing his thanks, and like the real man that he was, he said, "Doctor, you have helped me more than anyone ever did in my whole life. You have given me a new conception of myself and made me feel in regard to myself as I never felt before."

I had awakened in him a higher self-consciousness or an appreciation of a higher self hood, and the memory that I have of hundreds and hundreds of such experiences is to me one of life's greatest rewards.

"Conversion is suggestion just disguised,
The new man, is the old man hypnotized."

It is a great thing to have confidence in human beings; faith in humanity is faith in God. It is to recognize the divine in human life.

The individual or individuals who have helped me the most

in life have been those who were able to discover the germination of a higher selfhood as an actuating impulse in my own life and conduct.

ILLUSTRATION NO. 31.

Pulmonary Tuberculosis.—In a southern town a few years ago the thermometer suddenly dropped and the weather was uncomfortably cold. At the hotel a lady from a different state, in a well-advanced stage of pulmonary tuberculosis, was visiting. Cough, cough, cough was all that she could do. **Her weakness aroused my sympathy,** and I said to her: "Mrs. Blank, I can help you a great deal by suggestion, and should be glad to do so while I am here for the pleasure I should get out of seeing you benefitted."

"Why, Doctor Munro, I have consumption. Pray, how could hypnotism help me? This is no imaginary disease."

"Mrs. Blank, you are evidently very nervous. I heard you say you did not sleep two hours in all last night, and I noticed that you ate practically no breakfast this morning."

"Yes," she replied, "I am so weak and nervous I can scarcely walk. **This bandage on my hand** is the result of an injury received from a fall yesterday. No, I cannot eat or sleep, and this miserable weather is terrible on me."

She had a forlorn, downcast look, but I honestly believed that I could benefit her.

"Mrs. Blank," said I, "by suggestion in the hypnotic state I can quiet that irritability of your nervous system, give you a good, refreshing night's sleep, and yet you can relieve yourself by expectorating when necessary in your sleep. **Getting**

a good night's rest, you will conserve your energies and will awake with a good appetite and strong, quiet nerves. Then, as you eat more, sleep better, and get stronger, I will get you to breathe deeper and take in more oxygen. **The increased amount of air** will mean much to your general health, for oxygen is a food that many people do not take in sufficient quantities. Along with the influence of more oxygen upon all bodily functions will be an increase in elimination, both of carbon dioxide from your lungs, and from a freer activity of all bodily functions. **"In your particular case** I have confidence in the benefit to be derived from deep breathing in other ways. Increased function means increased blood supply, and by breathing deeper your lung substance will be better nourished and its resistive powers increased, and your chances to recover strengthened ten to one as compared to the present. There are other ways that suggestion would prove of benefit, but though you could not understand if I attempted to explain them to you, I feel warranted in saying that I know you will be benefited to a remarkable degree."

" Doctor Munro, **I am ready whenever you are,** and as often as you see fit to give this treatment," she replied.

Calling her friend, Miss Blank, into a room to be present at the time of the administration of this treatment, I proceeded to put her into a condition of suggestibility and gave suggestions to quiet her nervousness, restore more plentiful and refreshing sleep, inflate the lungs, and, above all, to stir all latent psychic activities into action, to increase her resistive powers, etc.

This young lady present told me that when she was a school girl Mrs. Blank was a fine singer and had a lovely voice, so at another time while she was hypnotized I gave her a suggestion that **she was again a school-girl,** and was going to sing while her friend furnished the music. The song was the " Angel's Serenade," and she sang, too. She reached the highest note in " Hosannah in the highest, Hosannah to his name."

I then appreciated as I had never done before with any patient, what I had done for her. All that I did was out of kindness and sympathy, but with optimism and faith. There was no money in this case. There was no selfish motive in it.

After four days she had been sleeping, eating, drinking, exercising, and singing as she had not before in years. **Six weeks later** I learned indirectly from her husband in another town in that State that she had gained six pounds, and was rapidly improving every day.

When I left the town where I treated this lady, she thanked me sincerely, and gave me a note which she had prepared to send to me at the train by the porter. In this she expressed her gratitude that she had received through me the ability to **eat and sleep,** for **the relief from pain, nervousness,** etc., and ended by saying, **" You have put into my life a bit of blue, where all before was smoke and cloud."**

Four years later this lady was enjoying life and much improved in health.

I shall hope that every reader of these pages may do as much for many individuals who do not need medicine, but do need to have aroused in them **a self-consciousness of dormant potentialities awaiting utilization.**

CHAPTER IX.

THE OPINION OF A "NEUROPATH" AND OTHERS.

The inconsistency of some men and their attitude toward certain phases of psycho-therapy but reflects their own limited conception of the subject.

Prof. F. X. Dercum has thought fit, in his work upon Suggestion, Hypnotism, Etc., to classify the phenomena of hypnotism as belonging **"unequivocally to the domain of hysteria,"** and asserts that **"the state of hypnosis is beyond doubt pathologic,"** but remarks that **"suggestion without hypnotism is susceptible of scientific application and is often profound and far-reaching in its effects.** So easily do men acquire a one-sided way of seeing things! **Their outlook** is colored by the hue of **their own subjective limitations.**

Dubois, on the other hand, says: **"The suggestible condition is normal.** One can boldly say that everybody is hypnotizable and suggestible. The subjects who prove refractory are those who are temporarily in an unfavorable psychological situation; under the sway of skepticism, fear, or distraction."

On the other hand, *the pathologist of one of our greatest Eastern universities, a medical school **second to none upon this continent,** whose graduates all over the United States reflect the high character of their alma mater, in an unsolicited letter

*Personal letter to the author from Dr. Allen J. Smith, pathologist to the University of Pennsylvania and formerly dean of the University of Texas.

in reference to my work among the physicians, commits himself as follows: **"If it be of any value to you,** that I should express an opinion of your efforts to disseminate a more intelligent idea of the value of suggestion in the treatment of disease, you are more than welcome to this note. I do not think your claims are in any way excessive, as I can from experience substantiate all I have heard you say as to the efficacy of the measure as an adjunct in ordinary therapeutics. Your explanation of its mode of action, while necessarily not of completeness, I believe to be based on sound principles, and your methods of inducing hypnosis in order to effectively apply suggestions, have added, to my mind, several valuable details to the methods commonly taught. I am particularly glad to see an effort to have suggestion applied in a logical mode to **appreciated pathological conditions** as underlying the manifestation of symptoms, rather than made in an indiscriminating way for the mere relief of symptoms without concern for their cause."

The professor of principles and practice of medicine in one of our great Western universities remarked to me: "Munro, I have been to Europe five times within the last thirty years and have kept up with the progress of psychotherapy **from the early Charcot days** to the present time. I have at least thirty volumes written by as many different authors in my library upon this subject, and I do not hesitate to say that **you have a simplified conception** and easy method of teaching psycho-therapy that should be in the hands of every American physician. Now, take my advice go and give it to them in a book."

It is hard for me to conceive of a man occupying an important position in the medical profession clinging to such a distorted, antiquated conception of this subject as that enunciated by the prominent neurologist before mentioned, **unless he is himself** in a psycho-neurotic condition, which the reading of his comments upon hypnotism and suggestion would indicate.

Out of between four and five thousand men put into a degree of suggestibility by the method I have explained in a previous chapter, with the assistance of **as many American physicians,** to **a degree that anesthesia could be induced** by suggestion, during the past seven years with a success of **at least ninety-eight per cent,** the only failures were upon **hysterical or extremely neurotic** individuals. In all cases **the more normal nervous organizations** made the best subjects for demonstrative purposes.

The phenomena of hypnotism, and all forms of suggestion, are **in accordance with the normal physiological processes. It is a physiological** condition, and to conceive of it as being anything else, shows the hysterical, **perverted mental condition** of the man who is attempting to hypnotize the profession into believing otherwise.

Between these two great American medical schools situated as they are, on the Atlantic and the Pacific, hundreds and thousands of American physicians, many of them occupying professorships in other reputable medical schools and **standing high in the profession,** have said to me, "I know from experience that what you say in reference to the utility of suggestion in the practice of medicine is true."

So, in the face of the facts that I have presented in the preceding pages, upheld as they have been by **physicians of the highest professional attainments,** I am constrained to believe that the man who opposes the judicious, conscientious use of suggestion in any form applied in the hands of the well-qualified physician as an **adjunct to his therapeutic resources,** does not know any better.

If suggestion be of value at all, the most efficacious form of suggestion is the most valuable. It is all hypnotism or it is all suggestion, **each is a phase of one and the same thing, pertaining to psycho-therapy,** a mode of influence, and the **personality of the man** who is using it determines its **use or abuse,** just as is the case with all other therapeutic measures.

It will be twenty-two years before my day of Oslerization comes, and I hope to be able at some future time to give the profession a more scientific presentation of the subject at hand, backed by additional facts, supported by new evidence tests and clinical experiences.

The majority of cases that I have reported have been those treated for my colleagues and the facts set forth in all such cases **can be substantiated by their testimony.** My explanation of the *modus operandi* is in accordance with modern scientific knowledge and stands upon its own merits. **The permanency of the results** of suggestive therapeutics depends entirely upon the **quality of the individual subject's nerve and brain plasm.**

The least satisfactory results are obtained in hysterical, neurasthenic, weak-minded, and degenerative nervous and mental organizations, yet **in this very class** of unfortunates it has

within it the promise of **more benefit** than can be obtained by any other method of treatment.

For seven years I have made good my claims for the efficacy of suggestive therapeutics in the presence of **critical physicians** and I am ready to **stand by the facts** as I have found them, notwithstanding the opinion of a **few psycho-neurotic neurologists** who seem afraid of encroachment upon their specialty if this branch of professional equipment became a part of the general practitioner's therapeutic armamentarium.

The cases here reported are given simply as an index to the **broad scope of the usefulness** of suggestive therapeutics in its application to the general practice of medicine and surgery, as yet only partially appreciated by a small portion of the medical profession. The subject, when studied in its broadest aspect, is some day certain to occupy the prominence in therapeutics, that it so eminently deserves.

The more intelligent and better educated laymen are becoming wide awake to its importance and there are those in the profession who are ever ready to adopt **what is true and useful** notwithstanding the prejudice of the ignorant and superstitious element of our age.

Physicians who have studied and employed these methods have frequently said to me frankly: "Suggestive therapeutics is all right, but there is no money in using those methods; the people prefer to pay a man who will **exaggerate their symptoms,** as is usually done by one who does not appreciate the psychic factor in his consideration of the symptomatology."

What we see in our patient's symptoms depends altogether upon the way we see it. **As our mental perspective broadens,** we interpret symptoms in a new light and what we see has a new meaning.

By all means let us "tell our patients the truth" in medicine and in religion and education and on all lines, but let it be "the truth" as **the more enlightened people see it.**

Absolute knowledge on any line does not exist.

Because we can study anatomy and pathology with the miscroscope and the test tube, we are liable to overlook the factors of human personality of which anatomy, physiology, and pathology are but expressions or manifestations.

We may not know what the mind is, but we are learning what it will do, and if mental methods of treatment will get results, **then as broad-minded men** we want them, for we want anything that will alleviate sickness, weakness and unhappiness and help to cure disease.

A well-known physician who did over one hundred major surgical operations a year, for fifteen or twenty years, very earnestly remarked that as soon as he began to **study the results** of these cases for one year, five years, and ten years afterwards, his conscience hurt him so that he now treated his patients more conservatively; that while such work was far less remunerative, the results, so **far as his patients were concerned,** were much more satisfactory, and that he himself slept sounder and was less disturbed in his dreams.

All over the country physicians have called my attention to cases where surgical intervention has been resorted to for

the relief of some **psycho-neurotic condition, associated with a minor structural abnormality,** where the symptoms were only aggravated instead of benefited by surgical procedures. **Yet in these very cases** the operation was a " brilliant success," because the temporary psychic effect gave the patient a boost, which enables the surgeon to collect a good fee and hypnotize himself into believing that he was all-important.

Other physicians say that while they recognize the value of these methods of treatment, they find that they feel as if they were carrying a heavy load of responsibility on their shoulders which is too burdensome for them to endure. They feel as if they were assuming the responsibility that the patient should take upon himself. **The fault in such cases** is not with suggestive therapeutics, but with the physician's methods of using it. **The physician himself** was probably in need of psychopathic treatment, for the real aim in the application of suggestive therapeutics is **to help your patient to help himself.**

No kind of work is more conducive to the mental and physical vigor of a physician than the effort to make suggestions that will produce such sense impressions **as will give rise to healthful mental states** in your patients, for the very attention on your part to such ideas causes the effort to be **of therapeutic value to you** as well as to your patient.

CHAPTER X.

SOME OTHER PRACTICAL POINTS.

Unquestionably the fine art in applying suggestive therapeutics lies in the employment of suggestion without an effort to induce a sleep-like condition. Yet, if the individual can be induced **to act upon and execute your suggestion,** either consciously or sub-consciously, it is by the use of the same method; call it reasoning, persuasion, advice, preaching, education, suggestion or hypnotism.

Upon one occasion when I was **standing by a cigar stand** with two physicians, and holding in my hand **a small phial of water,** a third physician, a stranger to me, walked up and asked, "What is that in your hand?"

"**Liquid electricity,**" was my reply.

"**Liquid electricity;** why, what is that and what is it for?"

"**It is used locally** as an anaesthetic, to relieve pain, cure headache, or to extract teeth and do minor surgery," said I. "Hold out your arm and I will demonstrate its efficacy."

The physician extended his arm and rubbing some of the water on the back of it for half a minute, I withdrew from my pocket a small steel pin, and holding it between my eyes and his, said to him, "**You see this pin.** I am going to stick it through a fold of skin on your arm, but **you will not feel it.** Your arm is perfectly dead and if that hurts you in the least, let the physicians present know it. Look at it; here it goes," thrusting the pin through a large fold of his skin.

" Did that hurt you? " asked one of the physicians.

" Not the least bit," was his reply.

Taking me by the arm the first physician said, " Come back this way, Dr. Munro; come back with us Blank." In his office he turned to me and said, Dr. Munro, shake hands with Dr. Blank."

" I want some of that preparation of yours," said he.

When I explained that the medicine was only water and that I had been talking to the other physicians present about the efficacy of suggestion, he laughed heartily and seemed to appreciate the experience.

Such experiences have been mine in hundreds and hundreds of instances, not only experimental and demonstrative, but also with a direct therapeutic aim. I state this experience in detail to bring out this point—**the unconscious use of suggestive methods is the most effective.**

In three-fourths of the cases where an individual requests that he be placed in the hypnotic state, we fail to get him into a state of suggestibility sufficiently effective **to induce anaesthesia** by suggestion, but by **suggestion in disguise,** we frequently succeed in a hundred cases, consecutively without a failure. A physician in a Western city **questioned the above statement,** as have many other physicians who had to be shown.

Upon the occasion of my lecture and demonstrations, one physician, after inducing hypnosis, proceeded as usual and induced anaesthesia and made other tests. **Then another did the same** upon an entirely new subject, to the extent that a large pin was thrust through the fold of the man's face without his

evincing the slightest evidence of pain, and he also was made to sustain a weight of 200 pounds on his body with his head on one chair and his heels in another, to demonstrate the efficacy of suggestion.

At this juncture the physician who had questioned our ability to successfully hypnotize such a large percentage of individuals, asked if I called that hypnotism. "Why," exclaimed he, "you are getting those men to do that **through auto-suggestion."**

"Certainly, doctor," was my reply.

"Well, why don't you call your work by the right name and say you are demonstrating and teaching **suggestion and auto-suggestion?"**

Other physicians present who were men of the highest professional attainments, assured the physician in question that they had never witnessed more successful demonstrations of the efficacy of suggestion, having seen work both in America and Europe, by competent men.

The extreme ignorance manifested by some men in regard to the practical and theoretical phases of psycho-therapy is pitiful. **They expect to find** in hypnotism some **uncanny influence by** which they can dominate and control people without regard to their wishes or knowledge, as has been claimed by every kind of outlandish faker advertising to teach all sorts of absurdities.

The only class of people that we can **dominate,** as distinguished from simply aiding them to execute an idea or series of ideas, is those of an unstable nervous organization, in whom a consciousness of self-control has never been evolved. **Such**

people are so suggestible that they readily take suggestions put in the form of positive affirmations in the waking state, but for therapeutic purposes they are the least satisfactory patients, although the very ones that most need our help, and the class of cases for whom suggestion is more useful than any other measure.

I have experimented with hypnotism and suggestion in every possible manner, both for amusement, demonstration and therapeutic application. The more normal, reliable and strongest nervous organizations have always produced the most satisfactory results, because they could best exercise self-control and were better able to act upon and execute a suggestion both consciously and sub-consciously. We can treat by suggestion any individual who seeks our services as a physician.

Never, under any consideration, let a patient suggest to you the kind of treatment you must adopt.

In the case of unstable and degenerative nervous organizations, the problem is to bring about those conditions that increase their protoplasmic energies, as well as to direct those energies into normal, useful, healthful channels. I have often prescribed a placebo to satisfy the patient, while I only too well realized, that his benefit and recovery depended altogether upon my influence upon his habits of thought and conduct.

A neurotic lady for whom I prescribed a teaspoonful of compound rhubarb and soda mixture at bedtime for sleep, and advised to relax and breathe deeply and rhythmically for ten minutes when she retired, so the medicine could have full effect, complained that she slept so soundly that she felt "dead all over" the next morning. I accepted that as evidence of a splendid re-

sult of the treatment, but advised her to **reduce the dose one-half,** drink more water, and take more exercise in open air and sunshine, assuring her that the "dead feeling" was only her "nervousness dying out."

Never use hypnotism or suggestion for amusement upon any occasion.

The physicians over the United States who have felt that their practices were injured by their use of suggestion and hypnotism have been mostly those who have given parlor entertainments, etc. **I have yet to find a single man** who employs suggestive measures in a dignified, conscientious manner, but whose success has been augmented both therapeutically and financially.

I can cite some men who have stated to me **five years after** taking my instruction in suggestive therapeutics that the knowledge derived from the one lesson had benefited them more than a three-months' course of post graduate instruction. **They were men** who had not before **realized their own worth,** and by the lesson in suggestive therapeutics they awoke to a **higher appreciation** of themselves.

Contact and close proximity breeds sympathy between two people of **opposite sex,** and when an easily impressible neurotic woman seems to be possessed of the hallucination or self suggestion that you are unduly fond of her, a single suggestion or a look of indignation is quite sufficient to plant a sense impression of an opposite character that will dispel her delusion.

It has been asserted that a patient who has been frequently hypnotized has been robbed of self-reliance and become so helpless that he must lean upon his hypnotizer for support. **On the**

contrary, I have frequently planted suggestions into the mind of a patient that have rendered them so independent and capable and self-reliant that they have refused to have further suggestions from me, taking their lives into their own hands, being guided by their own reason, while we remained the best of friends.

A man had been so crazed by a long drunken spree that he became delirious and rushed out of his house in the dark, ran into a fence, and landed in a neighbor's house, begging him to protect him, his face bleeding from the obstacles he had encountered. Beside his bed was found an iron poker and on either side of him were respectively a pistol and a large knife. His stomach had at last become his best friend and given him a chance to end his siege of alcoholic poisoning by rejecting all whisky he attempted to put into it, as well as all medicine given for the relief of his miserable nervous and mental condition. He felt, however, crazed as he was, that I was his friend and I did my best to prove worthy of his confidence.

I placed a cold towel upon his forehead and began my suggestions to hypnotize him by telling him that the cold application would quiet him all over and make him drowsy and sleepy, and that he would go to sleep and sleep soundly all night and awake in the morning feeling all right. Though I had secured thorough relaxation, with his eyes closed and with him breathing through his mouth, when I suggested that "this cold towel will put you to sleep and you will sleep sound all night," he took a deep inspiration and said, "Lord grant it," showing how he acquiesced in the treatment. He was hypnotized, and

suggestions were given to quiet all nervousness, to relieve his irritable stomach, to get him to sleep soundly all night, to excite a disgust or antipathy and hatred for whisky; and above all, to awaken within him a consciousness of manhood and duty to his family.

He slept soundly all night from 5:30 p. m. until 7:30 a. m. the next day, and as I approached the front door on my return visit, his wife, whose nervous system had been shattered by such experiences for several years, met me with the exclamation, "Oh, Dr. Munro, do you reckon Mr. Blank will ever wake up?"

"Why, certainly, Mrs. Blank; he is breathing, is he not?"

"Yes, he has been resting nicely, and I was able to retire last night and get some sleep for the first time in three weeks."

Upon awakening the patient in question, who was a large, strong, well educated, successful business man, I congratulated him upon having a good night's sleep and assured him that he would not care for more whisky and was going to be a man after that.

That evening I said to him, "Mr. Blank, I desire to put you to sleep again," and extending his hand, he said, Dr. Munro, you c-a-n-t do it. I thank you very much for the treatment last night and **shall always appreciate it,** but I do not expect to touch any more whisky and I shall get along all right."

I assured him that I was very glad indeed to hear him talk that way, and that for his wife's and daughter's sake, as well as his own, I knew he would feel happier. However, I turned to an attendant and directed that a **placebo capsule** (of powdered licorice root) be given at eight o'clock and in case he did not

sleep soundly by nine, to give a second capsule, suggesting to the patient that he would sleep soundly all night. **He refused hypnotic suggestion** but took the placebo capsules and slept soundly.

It is very easy to get an individual to accept a suggestion that is in accordance **with his natural desires. Some people do not want to get well.** They enjoy the sympathy and attention of an over anxious family *ad nauseum*. **In such cases** a suggestion given to set up a reaction may become necessary.

A physician had a pneumonia patient who had insisted that he was going to die on a certain night. The family had asked that another doctor be called in and that each of them stay on watch during the night.

The attending physician had kindly assured the family that there were no alarming symptoms and also did all he could to reason with and reassure the patient. **Nevertheless** at the appointed time the young man sent for his family and began bidding them good-by, when at that juncture the attending physician walked into the room, where the new recruit had for two hours been on watch.

He was a man who did things in his own way, so he insisted that all the family go out of the room and demanded of the patient, as if he was mad enough to fight, what all this commotion meant? When the young man assured him that he was going to die and could not get well, etc., the wise old physician answered, **"Well, die ——— you, die and be in a hurry about it;** make haste and let me see you." **Then placing his hand** on his forehead he called the boy by name and said to him kindly, "I am tired of all this foolishness. **You are going to get well.** You can't die,

it matters not how hard you try. Now, close your eyes and go to sleep and let me hear no more from you." **The patient was relieved** of his morbid psycho-neurotic condition and made a nice recovery.

A hypodermic of one-tenth of a grain of apomorphine has served the author as a most valuable means of suggestion.

In some psycho-neurotic cases a **Paquelin cautery** heated to a cherry red heat before the patient's eyes and brushed with quick light strokes down the spine proves a most valuable expedient as a means of suggestion. **Hundreds and hundreds** of physicians are using the static machine at so much per treatment. **Says one,** who is honest enough to admit that it is only a suggestive means of treatment: "It matters not what be the trouble, **I give them all the same dose.**"

A man who will exercise the courage to do so can use suggestion and get results when all such subterfuges are worthless. **He can take his equipment with him** wherever he goes and the general practice of medicine is unquestionably the field for its most valuable and effective employment.

In my work among the physicians it has been a matter of observation that psychotherapy is being appreciated just in proportion **as culture and education** are most in evidence. **Its successful employment,** as with all other branches of medicine, depends largely upon the personality of the physician. **There is no disease or condition** where its use is contraindicated, provided the **right suggestions are given** to help the patient.

If used to benefit the patient, its employment will make friends for the physician. **No selfish, cold blooded physician** who

is in the practice of medicine solely for the money and who has not **his patients' interest** more at heart than the desire to secure a fee, can ever be a successful psychotherapist. **It is best employed** by the man who is most willing to stand up for his weaker brother, who is most anxious to help his patients to help themselves. Character, which is educated thinking, desiring, willing and acting is a valuable asset in the make-up of a physician's therapeutic armamentarium. With such an asset his conduct towards his patients will be governed accordingly.

CHAPTER XI.

THE PSYCHOLOGIC FACTOR IN OBSTETRICS.

It was once my pleasure to be present at a medical society meeting at which, from a psychological point of view, the discussions of a most highly interesting and instructive paper upon the use of **"Forceps in Obstetrics"** interested me very much.

One physician related his experience in a recent case where he, and another physician present, had found it necessary to make several prolonged and strenuous efforts at traction upon the fore-coming head before they succeeded in a delivery which resulted in a badly lacerated cervix and a most completely lacerated perineum, stating in the conclusion of his remarks that he found it frequently necessary to resort to the use of forceps, and for this reason he highly appreciated the paper.

Another physician referred to a recent high forceps operation, and the difficulty in applying forceps before the head began to descend and while the os was as yet but partially dilated. **A third referred** to the frequency with which he had found it necessary to resort to the use of forceps in obstetrics, and how he dreaded such ordeals. **Still another** speaker emphasized, among other valuable ideas, the small amount of traction with which she had been able to deliver her forceps cases, even while the patient had been thoroughly chloroformed.

Among those who discussed the paper was yet another, a large, self-possessed and magnificent looking physician, a little past fifty-five I should guess, who rarely ever had to resort to the

use of forceps, and he urged the advisibility of not being in a hurry, and giving the natural physiological processes time to accomplish their work, rather than of hastily resorting to instrumental assistance or interference.

I do not claim to be perfectly accurate in my passing references to the discussion to which I have referred. **But the features brought out in those discussions** illustrate conclusively the importance of more attention being paid to the psychologic factor in obstetric practice.

It was quite evident that the large self-possessed physician to whom I referred did appreciate the psychologic factor, and hence, " rarely, if ever " had to resort to the use of forceps; and it was also equally evident that of those present, some physicians were rather inclined to be nervous, and unconsciously had been a potent factor in producing the condition in their patients which necessitated the use of instruments.

More than in any other part of the practice of medicine, in obstetrics the physician should be well poised and self-possessed, and should maintain a quiet demeanor and keep well conserved his mental and nervous equilibrium in the presence of an excitable, frightened and nervous patient.

In the early years of my professional work I assisted three times in the instrumental delivery of a lady who at the time of her fourth delivery fell into my hands. **Knowing the difficulty** that she had experienced with her previous deliveries, and seeing the depression that her condition and the approaching ordeal produced upon her, I had her come to see me quite frequently and positively assured her that I had her on a treatment that

would insure a safe and easy delivery, and before her confinement I had eliminated all element of fear. When I was called to see her at the time of delivery, after making a careful diagnosis, I again **positively assured her** that it was absolutely impossible for her to do otherwise than get along nicely, and I have never attended an easier delivery than hers.

Where it has been possible, it has been my habit to see the prospective mothers often enough before parturition to keep well *en rapport* with them. I have frequently placed them in the suggestive state two or three times during the last weeks of pregnancy, in order to insure a perfect psychological attitude at the time of delivery.

The influence of the mind upon metabolism is well established. To keep our prospective mothers in a buoyant, hopeful, cheerful state of mind helps to prevent albumenuria, eclampsia, and other complications. All other essentials requisite to the well-being of our patient of course should not be overlooked. A wholesome vegetable diet, with milk and eggs, as well as regular out-door exercise, should be insisted upon.

When called to see your patient when in labor, manifest a kindly interest in her well-being and make her feel that you are kind, firm, and self-sufficient, by your conduct in her presence. After carefully making your diagnosis, do all you can to calm her spirit, assuage her fears, and inspire her with confidence in your ability and intentions to do what is best for her. **Assume absolute command** of the situation and allow no environmental influence, such as over-anxious expressions of friends, to influence her. Let her feel the masterful, helpful, encouraging influence

of your personality, as well as get the benefit of your kindly assistance.

When the members of the medical profession become awake to the importance of the psychological factor in obstetrics, forceps deliveries, lacerated cervices and perinei will be far less frequent.

While in a Southern city four years ago, a well-known physician requested me to see with him a woman in labor, and I quote the following from his report of the case: "About 2 a. m. I was called to Mrs. W., a young primapara, who was frightened, exceedingly nervous, and hard to control. At 4 a. m. Doctor Munro came at my request and demonstrated the efficacy of suggestion in a most satisfactory manner, by substituting for the extreme nervousness a condition of placid repose. The rapid heartbeats became normal, the patient slept peacefully between contractions and 'bore down' to her pains without complaint. It proved especially efficacious during that nagging stage of dilatation. Later on, with the aid of only a few drops of chloroform, the case was conducted to a finish with perfect satisfaction both to myself, my patient, and her friends. I am fully convinced that when physicians learn to practice intelligently what for ages we have all been practising ignorantly, i. e., suggestive therapeutics, then the obstetric couch will be robbed of its horrors."

TECHNIQUE OF APPLICATION.

Labor is well established, the os is dilated to the size of a fifty cent piece, more or less, the contractions and all indications

are that there is to be no cessation of symptoms until your patient is delivered.

She is begging you to do something for her. You have made out your diagnosis and reassured your patient, but now the severity of her symptoms is such that she feels that she must have help. **You have the reputation of using chloroform,** and she would not be satisfied unless you did use chloroform. You are waiting for the right psychological moment, she has patiently endured her sufferings and feels that she can hold out no longer without help that she has not received. **You have assured her** that she is doing well, that every indication is for a safe delivery, and that you are going to use chloroform so that she will not suffer. **The urgency of the occasion** grows more imperative and you decide to make another digital examination.

As this is completed, say, " All right, madam, be patient and bear strong and hard to the next pain and **just as that leaves you** I will give you chloroform so that you will get well under its influence by the time another contraction comes and you will not suffer any more."

Just as the contraction has expended its energy, synchronously with the first inspiration after a long bearing down, shake about **thirty drops of chloroform** upon a handkerchief in a paper cone or that you have placed in a tumbler, and placing that close over her nose and mouth, suggest to her strongly, " Breathe this down now, and go to sleep." She takes a deep inspiration, and you quickly and strongly suggest, **" Breathe it in again,** and now again, away down deep."

The three deep inspirations from the thirty drops of chloroform administered in this way at this particular moment have sufficient physiological effect to annihilate completely the receding contraction; and also the three deep inspirations in succession, together with the physiological effect of the chloroform, secure the thorough relaxation of your patient. **She is now in a receptive condition,** and you must quickly, but emphatically and distinctly, follow this up with your suggestions to get her into a deeper suggestible condition or into a hypnotic state.

So, removing the cone or glass about two inches from her nose, you proceed to suggest, "Now, go to sleep, sleep, sleep, sleep. Now you feel quiet all over. Your muscles are relaxed. Everything is dark to you. You do not hear anything but my voice. You are drowsy and sleepy, s-o-o-o-o sleepy. You feel the sleep coming over you. You are going to sleep. Sleep, sleep, sleep. By the time I count ten you will be fast asleep. One, two, three, four, five, six, seven, eight, nine, ten, and you are asleep, fast asleep. By the time I count five you will be sound and dead asleep. One, two, three, four, five, and you are asleep, fast asleep, sound asleep, dead asleep, and you will not awaken now until I tell you. Every second your sleep becomes sounder and sounder and deeper and deeper. You will not hear anything or feel anything or know anything except what I tell you. Sleep on quietly now until I awake you."

Your patient is now in a deeper condition of suggestibility, but you want to take an additional precaution to secure more thorough relaxation, so, without the addition of more chloroform

you bring the cone or glass closer to her nose and suggest, **"Breathe deeply,** deeper yet, once again away down deep. There, now, you are thoroughly relaxed."

Then stroking her forehead gently, make suggestions about as follows: "Sleep on quietly. Now, your nerves are getting steady and quiet and strong, steady and quiet and strong all over. By the time I count ten the last bit of nervousness will be gone and your nerves will be steady and quiet and strong all over. One, two, three, four, five, six, seven, eight, nine, ten, and your nerves are steady and quiet and strong all over."

"Now, on account of the sedative effect of the chloroform upon you, you feel all pain or aching or soreness or hurting about your abdomen or back or womb going away, you are getting easier and easier, and by the time I count five you will be perfectly easy and not suffer any more. One, two, three, four, five, and you are perfectly easy.

"Now your labor will be regular and normal, you will labor hard, but will feel no pain. Your contractions will be strong, the mouth of your womb will dilate and open easier, but you will feel no pain.

"Sleep on and when the next contraction comes, reach up your hands and bear down strong and long, but you will only feel a pressure; you will not experience any pain."

As the contraction again becomes evident, say to your patient, "Bear down hard now, it will not hurt you. That is fine; stronger yet, more yet! There now, take more chloroform and go into a deeper sleep."

Here you put about **twenty drops of chloroform** on the handkerchief in the cone or glass and make a few additional suggestions about as follows: "Sleep, sleep, sleep, sleep, breathe deeply, sleep sound. Now, sleep on quietly until the next contraction and then don't wake up, just reach up your hands and bear down, but sleep on."

As this contraction recedes you give about ten drops more of chloroform and make a few additional suggestions.

By that time your patient is sufficiently amenable to suggestion to the extent that I have frequently had patients **go two hours in labor without more than the slightest complaint,** getting them to relax thoroughly after each contraction and making a few additional suggestions.

Toward the latter part of the second stage of labor, with the last two or three expulsive pains, it is best that you give chloroform at the beginning of the contraction for its physiological effect, using it freely and effectively as it enables you to manipulate the head and perineum and render such assistance as best to prevent laceration.

I have yet to see the first case of post partum hemorrhage in a case where suggestion was used; though I have always followed the expulsion of the child with my left hand and grasped the fundus of the uterus after Crede's method. **Post partum hemorrhage** is largely a nervous phenomenon and properly directing and controlling the psychic factor is a safeguard against it, though I never neglect any other precaution, consequently I have never had any trouble on this score.

A rigid os indicates an irritable involuntary nervous system and it rapidly disappears when the psychic factor is properly directed as above outlined. **Your success will be in the direct ratio** to that in which you secure thorough relaxation of the patient and properly make suggestions.

The patient need not necessarily be asleep; a merely partial subconscious condition is attended with excellent results, provided you have the **confidence and co-operation of your patient,** and this it is your privilege to gain very quickly after you enter the room.

A nervous physician is undoubtedly a menace to the welfare of an obstetric patient, for nervousness begets nervousness and fear begets fear. Self-control and self-confidence on the part of the accoucheur carry, all unconsciously, a wonderfully helpful influence.

Don't neglect any other therapeutic resource. An obstetric patient of mine had two sisters, each of whom died of eclampsia in her first labor. The effect of such a family record was most depressing upon her. During the last weeks of pregnancy I saw her every few days and assured her positively that the treatment I had her on would prevent any such occurrence. She was a plethoric, full-blooded woman and the secundines were removed with practically no hemorrhage at all. A severe headache, extreme nervousness, and rapid, full pulse which followed, required not only large doses of veratrum hypodermically, but free bleeding also, as well as suggestion in the form of reassurance, persuasion and encouragement, with **large doses of calomel and jalap.**

To a patient who had aborted after four months and had considerable hemorrhage and was almost pulseless, I suggested strongly and loudly, upon making an examination, **"You will be all right!** Be brave, madam, you will have no trouble, etc.," though I proceeded to clear and pack her uterus.

In a case of twins, I "chloroformed" my patient with alcohol administered by inhalation and suggestion, used forceps on the first child and internal version on the second, with perfect success.

Ten drops of chloroform given to a patient after each contraction while she is thoroughly relaxed, passive, eyes closed and breathing rhythmically through her mouth, **and suggestions made in a monotone, conversational way,** to quiet nervousness and render the patient conscious that something was being done for her, is attended with excellent results, without any farther effort to induce hypnosis.

The confidence of the patient in her physician can be considerably augmented by properly directing the psychic factor in obstetrics, and the welfare and safety of the patient are rendered far more certain.

In a case of an abortion at five months, before the expulsion of the uterine contents, which was attended with much hemorrhage, I packed the vagina and put on T bandage, **hypnotized the patient, made appropriate suggestions,** and went away, returning in three hours to find that the patient had been easy, but upon removal of the packing both foetus and secundines came away together.

A patient who once has the assistance of a physician who properly directs the psychic factor will instinctively feel that she has never before had the right attention in her previous confinements.

A number of physicians of my acquaintance have been able to execute successfully the above described methods greatly to the satisfaction of themselves and patient.

Your success in obstetrics, as in all other classes of work, will be in direct ratio to the integrity and stability of your patient's nerve and brain plasm, on the one hand, and your ability to present suggestion properly, on the other.

CHAPTER XII.

TRAINING THE SUBCONSCIOUS SELF.

A RATIONAL BASIS FOR AUTO-SUGGESTION.

Every sense impression or perception or idea that has come within our individual experience through education or environment has left its impress upon the brain cells, and these brain cells stimulated by ideas of a similar character reproduce the memory pictures gathered by experience and this process is what is called thinking. Thinking in logical sequence constitutes reasoning. Thinking gives rise to mental processes or states of mind or conditions of consciousness that are constantly changing, so that the conscious mind or ego of one moment is not that of the next.

So inter-related are our psychical and physical processes that much has been learned of our subconscious psychic activities by observing the influence of the mind over the body.

The subconscious self corresponds to all mental and physical processes which lie beneath the stream of consciousness. We often flatter ourselves by believing that we control our thoughts, when, as a matter of fact, thinking is but a reflex of the sense impressions that have been made upon our cerebral cells by all that has gone to make up our experience in life.

Yet, education, travel, association with people, and all other like experiences, benefit us only as we react to them.

Every impression or idea that is made upon the conscious mind of the individual throughout his entire life is one of the factors that collectively constitute the training of the subconscious self. The result of this training constitutes our assets, as represented by body, mind and character.

Our ability to react upon and be benefited by the experiences of life is dependent upon an inherited quality of brain plasm, on the one hand, and education, on the other. **We can be benefited** by the experiences that come into our lives only as we are prepared by knowledge gained from previous experiences.

That which influences us most is what most persistently holds our interested attention. The kind of thought or line of endeavor that most receives our purposeful attention sustained by reason, will and determination, so reacts upon our bodies and minds that we unconsciously become moulded by that particular kind of work.

The mind, like the body, becomes strengthened or weakened by mental and physical action. The blacksmith who uses a sledge hammer day by day develops a muscle of steel, while the bookkeeper who lifts no more ponderous weight than the leaves of his ledger from week to week, has muscles that have become atrophied and shriveled. **The man of genius** is only distinguished from other men by his exceptional power of attention to one given subject. On any line of work in all professions the individual who becomes most proficient is he who most persistently gives attention to his specialty.

It has been well said that the mind set habitually and strongly in any one given direction loses the power to think upon

any other line. **The Christian Scientist,** who ignores the material aspect of disease, **and the physician** who does not appreciate the psychical, are good illustrations of the above statement. **The particular line of thought** to which we constantly give our attention, and by which we habitually act, makes us what we are.

To be strong, capable and free is the ideal that every individual should strive to attain, but strength in mind and character cannot be attained by neglect of the body, for the interdependence of mind and body is such that the highest development of the one quality depends upon the other for its support.

Use your faculties and live, grow and develop, is a decree of Nature from which there can be no escaping. Some day, sooner or later, each individual awakens to the realization that his life is a fight between himself and the entire world. **We are so related to each other,** however, that the duty of the individual and his dependence upon other individuals and their dependence and relation to the great whole must never be left out of consideration. Yet, **the individual** must stand upon his own feet, see the world with his own eyes, do things with his own hands, and interpret the problems of life with his own intellect.

To be prepared for this conflict, this contest, this body, mind and character tryst, is the problem of training the subconscious self. **Life itself** is the greatest incentive for living, and to attain the highest development and expression of the subconscious self renders the individual capable of enjoying life, not only for his or her own sake, but because to him or her comes a double pleasure of being better equipped to help make life more worth while to others.

Since we are endowed with a little infinitesimally small portion of the universal life, wisdom, intelligence and force that exists in the universe, the highest privilege of every human being is that of being a chooser; the privilege of exercising a choice between what shall and what shall not receive his attention. **The ideas which we encourage** become stronger, last longer, and exercise the greatest influence on our habits of thought and conduct.

Even in the case of what are commonly held to be involuntary mental processes which crowd themselves upon us unwelcome and unbidden, when we are consciously all unaware of their existence, coming as the result of previous experiences—**we can encourage** those that are desirable and inhibit others that are undesirable to a very large degree. **But while we can only partly** inhibit those memory pictures that are undesirable, we can as choosers decide what shall in the present and in the future claim our conscious, intelligent attention.

Everything that claims our conscious attention strongly and persistently constitutes "food stuff" for the subconscious self, which contributes to the remoulding and rebuilding of our physical and mental constitutions. **Character itself** is evolved in accordance with this same law.

As choosers, then, the privilege is ours to be open and receptive to whatsoever is good, true, and useful in the realms of thought—as expressed in the literature of poetry or fiction, philosophy, religion, or science, or from association with individuals —that may be of use to ourselves or other human beings. We should study it honestly, appropriate its truths, and live by them in all departments of life.

In the same realm of human experience, with respect to whatever is not good and not true and not useful for our best growth and development, let us exercise the courage of our convictions and reject it, even though it has the time-honored sanction of conventionalism and authority. **We should let truth herself** sum up the case and guide our lives and conduct in accordance with the light and knowledge of the present age. **This is the clue to the correct training** of the subconscious self.

Then, too, since we realize the power of mind upon mind and the influence of the mind upon the body, both for our own good and for the benefit of others, we should encourage mental states that make us hopeful, optimistic, and cheerful. We should look upon the bright side of everything and strive to say and do something to cheer the lives of others. As we sow, that shall we also reap, is the law of Nature in the realm of both thought and action. **Whosoever uses suggestion to help others** is using the highest form of autosuggestion to help himself. Our effort to create healthful mental states in others reacts upon our own subconscious selves, so that what we are is to a great extent the result of what we have given to others.

Individuality and strength should be our highest and most constant aim in life.

The great subconscious self, with its millions and millions of living cells of brain and blood and bone and muscle, all reservoirs of expressive energy, is for us to educate, train, and develop in accordance with the laws of evolution. **Each individual is the maker of himself** in a far greater sense than is realized by the pessimistic philosophers of our age, who would surrender all to

heredity and environment. **The limitations set by heredity and environment** of course, are beyond question, but when once we become strong enough to think for ourselves and to rely upon the powers and capabilities inherent within the cells of our organism, then those influences that would fetter and mould a weaker individual and hinder bodily and mental growth and development become for us strengthening and wholesome exercise.

Each individual contains within himself an ideal man, and to bring forth this individual harmoniously and symmetrically developed in all the qualities of selfhood should be our constant endeavor. What the man or woman of the future is to be depends upon our habits of thought and conduct today. No proposition is more true than that by constant endeavor we can day by day gain in strength of body, mind and character.

The great trouble with the majority of people is that they have not an adequate appreciation of the potentialities and possibilities inherent within the cells of their own organism, which are ever ready to be trained into active, useful service. **Others are satisfied as they are** and they constitute a large percentage of our population. They are drifting along day after day without making any special effort at self-development and almost wholly dependent upon others to think and do for them. **Depend upon others** to think and act and do for you and you become incapable of thinking and acting and doing for yourself. That which makes a man strong in all the qualities of self, social, intellectual, physical, moral, business or ethical, is action, effort, concentration, persistency, determination.

Recognition of our defects and desire for self-improvement are the incentives which urge us to higher growth and development. Those who feel that they are self-sufficient and are all that they care to be, have not been stirred by the influences which induce a self-consciousness that gives rise to the impulse to make effort. Perhaps they are unfortunate and have not been awakened to a consciousness of what they are as compared with what they may become.

The hope of humanity lies in the law of the "survival of the fittest!" The great mass of the people do not think for themselves above the most elementary questions of life. In problems of health and education, ethical and moral ideals, their views are more a matter of inheritance than based upon intelligent conviction as the result of careful investigation. **The physician who can arouse them to observation,** reflection, and self-activity, is doing them the highest service that an enlightened mind can render.

The problems of health are the problems of life and pertain to all questions of human interest. Body, mind, and character are but reflections of the great subconscious realm with its inherited or acquired impulses, habits, instincts or ideals, and these, like the flower garden, need to be continually uprooted and reset. The false and barren and useless should be rejected, and new varieties planted in keeping with knowledge and experience.

Surely this line of thought has a practical application in the practice of medicine. Stand any day you choose on a street corner and see the masses as they pass, and with pencil and

paper in hand make a mark for everyone who is weak and living, minus the qualities of a normal, healthy individual, and you will find that at least fifty per cent of our population have weak bodies and imperfect nervous organizations.

The great majority of those who are sick need to be taught how to keep well, how to eat, how to drink, how to exercise, how to work, and how to sleep—in short, how to live. More than at any time in any age does the individual need self-reliance and the feeling of independence and freedom. This belongs only to those who have achieved sufficient self-hood to dare to exercise the courage to stand by their convictions.

Self-reliance is nothing more than one's own recognition of his or her ability to act and think and live according to the dictates of reason and judgment. Each individual has a different problem to solve. All people are not "born free and equal," so far as heredity and environment are concerned, but all are born with the privilege to think, act and do for themselves, that the greatest health and happiness may be maintained.

People as a rule are not sufficiently educated to take their lives into their own hands. In their efforts to do for themselves and to struggle with the problems of life, they make many blunders which react with ill results to both mind and body, and **as experts in the healing art,** our aid is sought to help them. **They do not always need medicine,** but they do always need education, knowledge and guidance.

The physician must have more than professional knowledge and skill. He should be an expression of the highest thought

and culture of his age, to be prepared to take his place as a leader and teacher of his fellow man.

The practice of medicine offers great privileges for real, genuine, unselfish service. The opportunities for being of real help to our fellow man are the greatest of any calling in the list of human achievement. In no other profession are such conditions offered for brain development, self-reliance, and altruism.

The people have a right to make every effort to keep healthy and strong without relying upon us to administer to their physical necessities. It should be a part of our work to help them to so help themselves and then the followers of the different non-medical therapeutic systems would no longer continue their hold upon the people.

So long as new-born babies come to gladden the hearts of the men and women of the world, physicians will be in demand. **While human endeavor continues,** accidents will happen and the surgeon will be needed. We have not yet subdued the mosquito so as to prevent his carrying malaria and yellow fever germs, or eradicated vice to prevent the diseases of physical degradation due to infectious germs.

The Klebs-Loeffler bacillus, the bacilli of anthrax, and typhoid fever, and the thousand other germs of infection do not respect even a healthy human organism, and for all these conditions the services of the physician will be invoked. **The astigmatic eye** and other refractive errors are here to stay to cause reflex disturbances and functional diseases of both mind and body. **Infantile diseases** will claim our little ones as long as it is human to err in dietetics and the world remains the abode of

Weischesbaum's bacillus of meningitis and other infectious diseases. **The great white plague alone** claims one out of ten of all human beings. In spite of our knowledge of mental therapeutics **women will grow tumors** and a million years of special effort will not annihilate the physical results of **inebriety** and **syphilis** or prevent insanity in its various forms.

The one sure event in the pathway of every human being is death, sooner or later, and the one hope of every individual is that his life will be prolonged. **Let us, then, do all we can** with all therapeutic measures when the people are sick, but by all means let us help them to keep well by teaching them how to live so far as possible to maintain healthy bodies.

The benefit to be derived from work and exercise and water and laughter and rest, food and companionship, education and environment and self-development in a thousand ways should be ever kept before them. All these things should be studied by the people and all this constitutes the correct training of the subconscious self.

CHAPTER XIII.

CORRECT DIAGNOSIS A SAFEGUARD AGAINST BLUNDERS.

It goes without saying that a good clinician has a wonderful advantage over the individual who has not had sufficient training and the necessary experience to interpret the symptoms of a disease, and quickly couple those symptoms with its etiology, pathology, prognosis and treatment.

As has been stated in previous pages, suggestive therapeutics should be applied with an understanding and comprehension of the anatomical and physiological relations of the organism as well as of the pathological conditions to be alleviated.

Good men in our profession who do not sufficiently appreciate the psychic factor in therapeutics are frequently so engrossed with pathology that they forget to tell the patient what he can expect in the way of recovery and to keep this idea constantly impressed upon him. **They do, however,** often impress him with the seriousness of his condition in a detailed explanation of its pathology, but they fail to inspire him with a conviction of recovery. **Such physicians** leave the patient depressed, and if, forsooth, he happens to fall into the hands of a quack who has sufficient personality to lift him out of the depression thrust upon him, and recovery is not incompatible with the pathology of his disease, the patient "is cured" and the physician's reputation is injured.

As bearing upon this subject, in a discussion of a paper read by me in one of our larger cities, one of the best known

men in the medical profession thus expressed himself: "Now, gentlemen, you know as well as I that there are a great many people in this city that have been treated by some of our very best physicians for months and years, and yet, satisfactory results have failed to be attained by them. **Yet, those same patients,** after going the rounds from one physician to another, finally land in the office of some of the most notorious quacks in the city, and do obtain the relief so vainly sought at our hands. When we know that such things as this exist all about us, it seems the time has come when we can afford to study some of the secrets of the quack, for what they can do for morbid processes, we can do also."

At that same discussion another physician in the course of her remarks said: "Doctor Munro dares to speak out aloud what all thinking physicians have recognised, but do not express, except at low breath, when among themselves."

This line of therapeutics is undergoing a rapid evolution, and the true and useful and good that is in it is being sifted from the false and useless. Those of our profession who take a stand against it are doing much to encourage the followers of the modern "creeds" and "cults," "ists" and "paths," who go to extremes in their views of the influence of the mind over the body.

People easily believe that which it is to their interest to believe. Physicians are educated to their view that medicine is the natural recourse of the sick man, and it is hard for them to recognize the psychologic factor, because it happens to be the basis of all forms of quackery. **Yet, the thinking portion** of

the American people are on the alert, and they are ever ready to accept and support anything true and useful, it matters not how strong their prejudice may have been. **Christian Science, weltermerism,** etc., have served a useful purpose. They have stimulated the people to reflect and exercise more self-control, but they have made, and are destined yet to make, many gross and painful blunders before their fanatical zeal is quelled.

In several instances within my knowledge disastrous results have followed the vigorous methods of those who use massage as a means of suggestion. In a case of acute articular rheumatism in a little boy of twelve, the inflammation which followed this treatment by vigorous massage was such that an amputation of the limb was necessary to save the little fellow's life.

In a case of diphtheria the methods employed served only to increase the inflammatory exudate, and a speedy death followed; whereas the timely employment of anti-toxin in diphtheria has reduced the mortality of that disease to a very small death rate.

A case of acute mastoiditis, resulting from a neglected middle-ear disease, was treated by the methods of the Christian Scientist whereby surgical intervention was withheld until too late to be effective.

In several instances it has come to my knowledge where appendicular abscesses were ruptured by massage with fatal consequences, to say nothing of children with gastro-entero-colitis who died under Christian Science psycho-therapeutics while legitimate, prophylactic, antiseptic, medicinal and dietetic methods were withheld.

I once witnessed the removal of sixty-five stones from the gallbladder of a woman who had been taught to ignore such " errors of mortal mind " ; but after becoming weak, jaundiced, and anaemic, with all bodily functions disturbed, she at last yielded to the rational advice of her friends in time to resort to surgical procedures for relief, and recovered.

At a Christian Science service not long since, just in front of me sat a young man who was rapidly losing his hair as a result of an infection of the hair follicles with the germ which causes seborrhoeic eczema. The psychic effect of his religion upon him was great, but the germs went on with their work just the same.

Christian Science was held before the attention of the audience by readings, songs and prayer, as a sovereign remedy for sin, sickness and death; but over on my left sat a lady in mourning. With her head drooped and lips closed tightly, she sat there, not at all receptive, and took her medicine, though her expression showed a consciousness that realized the mockery of all that was receiving her attention. Her face was sad because her husband was dead, and this experience was setting up a mental reaction to all the negations that fell upon her ears.

Over on my right sat a gentleman with eyes open like full moons and his lower jaw dropped as if it had no muscles to support it, with a well fixed gaze upon the reader of the suggestions that had been prepared to hypnotize the audience. He was suffering with locomotor ataxia, and though credulous, receptive and suggestible in the most complete sense, he walked away upon two " errors of mortal mind," usually called crutches.

Yet, physicians are far from infallible. All their patients do not get well, **neither does absolute knowledge upon any subject exist,** while every conception or theory or viewpoint represent some relative phase of truth to be determined by individual experience.

While we know what mercury will do in syphilis, and quinine in malaria, and sulphur in itch, and antitoxin timely administered in diphtheria, and what the result of corrected errors of refraction will bring in the relief of headaches and numerous functional disturbances, and what relief surgery will bring in gross pathological changes, etc., yet there are many conditions confronted in all lines of professional work in which **we do not know** absolutely what the outcome will be, and no physician has done his full duty until he has given his patient the full benefit of every therapeutic aid. The rule should be "While there is life there is hope."

Two cases here cited that have been brought to my attention will illustrate the blunders that may be made by too quickly jumping at conclusions without due appreciation of the psychologic factor in therapeutics.

A well-known physician and surgeon was consulted in reference to a patient of another physician with an incipient malignant affection of the cervix, and he strongly advised operative procedures as the only safe course to pursue. The operation was deferred, and several months later this patient was taken on a litter to a prominent surgeon in one of our larger cities. After carefully considering the case, together with the assistance of a well-known pathologist who made a micro-

scopical examination to determine the exact character of the disease, he declined to operate, as he believed this would only serve to transplant the disease to more vital structures and hasten her death. Discouraged and hopeless the lady finally yielded after much protest to the solicitation of a Christian Science friend, and consented to do so because this was the only promise held out to her for a possible hold on life. **After three or four months'** treatment by Christian Science psychological methods, that lady had gained twenty pounds and returned home, walking erect and strong, **and after three years** would occasionally call upon the consulting surgeon in her home town, who advised the operation in the incipiency of her disease, and laugh heartily over the incidents connected with her case. **The facts in this case** can be well authenticated.

Again in a Western city a gentleman about thirty-five years of age had been treated for pulmonary tuberculosis for a period extending over many months, and was finally advised to go to a higher and drier altitude, his physician assuring him that this was the only hope offered for him. He went to a town situated just west of the Rocky Mountains, and carried with him a letter of introduction from his home physician, together with a **report from a competent pathologist** showing sputa teeming with tubercule bacilli. **After examination and observation** for several days this physician advised the sufferer to go home at once and die among his friends and relatives. **He then sought the assistance** of a Christian Scientist, and after two days did return home inspired with hope, and having been able to sleep and eat under the psychic effects of their method, **he was much improved,** and

put himself under the care of a Christian Science " practitioner " at his home town. **When I saw him,** he was holding the position of city attorney, and in his hands **he held the report of the pathologist,** as unquestionable proof of the correctness of his history, which he flaunted while he enthusiastically related his experiences at one of their mid-week meetings, stating that he had gained thirty pounds and was **enjoying life, eating, working and happy.**

As illustrating another phase of the subject at hand, however, in another Western city a well-known physician advised an immediate operation for an incipient malignant disease of the cervix. **Seeing his patient a few weeks later** he very naturally greeted her and expressed his pleasure at seeing her looking so well. " Oh, I have never been sick, doctor. That was all an 'error of mortal mind.' I am perfectly well." **Her phraseology** at once " put him next," so with the salutation, " I wish you well, madam," he modestly left her.

Several months later she returned to his office. The temporary psychic stimulation that had for awhile held her up in spite of the existing pathological conditions, had reacted, and now that characteristic, sallow, cachectic hue which attends this disease was plainly in evidence. She was weak and anaemic, nervous and over-anxious about her condition. She had at last decided to have him operate, but she had waited too long, and there was nothing left but to leave her to face the inevitable.

In the first case of " malignant disease " it is probable that the pathologist was mistaken; and tuberculosis, under favorable climatic conditions, and when not too far advanced, **is by no**

means an incurable disease. **Good food, dry open air, sunshine and optimism** often do wonders in the way of giving the recuperative powers of such patients an opportunity to overcome pathogenic bacteria and re-establish a condition of health. **In less serious affections,** especially, should the influence that the psychic factor exerts, be well kept in mind before an unfavorable prognosis is rendered. For there are numerous instances in which the prognosis may determine the outcome of the disease, on account of the part played by suggestion in aiding or retarding recovery.

In many diseases, an exact diagnosis is not always possible, though few expert diagnosticians will admit this, and even in psychiatry and nervous diseases those that are amenable to treatment, either curative or palliative, are benefitted just in proportion as the bodily functions, both voluntary and involuntary, are encouraged into activity.

No possible harm can come to the individual by suggestive measures, used either with or without hypnotism, which are only a means of getting the individual to rely upon the properties, faculties and functions inherent within the biological elements of the cells of his organism. By suggestion we can stimulate all bodily functions, both voluntary and involuntary.

All other sane, sensible measures are, of course, not to be neglected, such as rest or exercise, dietetics, hydrotherapy both internal and external, relaxation, deep breathing and materia medica agencies, as the individual case indicates. **Yet, there are many cases,** not incompatible with complete recovery in which the patient would get well, due attention

being given to the psychologic factor, but which would not recover without its aid.

In all cases let us give the patient the benefit of the doubt.

CHAPTER XIV.

PHILOSOPHY AND RELIGION AND THEIR RELATION TO HEALTH.

From a psychological standpoint all religious services of all denominations are especially interesting. If we attend them to learn, we usually find our lesson between the lines.

The psychic effect of the comingling of several hundred male and female voices, with sentiments of love expressed in song; with the martial spirit of soldiers battling in unison and marching as conquerors from victory to victory; amid music and beautiful flowers, fine clothes and suggestive mottoes, and mystical carvings; all these combine to have a significance but little appreciated by one in a thousand of the people of our times. **They subtly and gently** stimulate all the involuntary cells of the body and temporarily lift the individual out of his self-conscious physical and psychical weaknesses, and, in general, **when free from emotional excitement,** prove to be an experience which, like other deviations, reacts with benefit upon both mind and body.

Suggestion is to be seen in all such experiences from start to finish. The methods adopted by the clergyman of getting *en rapport* with the audience; the unconsciously induced condition of receptivity by quartettes composed of male and female voices; the reading responded to by the audience, followed by a female solo; **all create a psychic condition** which renders the individual forgetful of self and his surroundings.

For the time being he is completely amenable to the sug-

gestion given from the pulpit orator, who from thirty to sixty minutes has the opportunity to create sense impressions and present ideas or suggestions that **are beneficial or harmful,** as the case may be. **They are wholesome, beneficial and helpful** suggestions just in proportion as they are the reflection of a broad, well educated, truth-loving mind or personality.

It has been my privilege to hear such men in all denominations, both Protestant and Catholic, Jew and Gentile, Mormon and Free Thinkers, as well as promulgators of Oriental philosophies and religions, containing **much that is true and useful and good.**

Just in proportion as the people are becoming sufficiently well educated to comprehend in some degree the cosmic order of the universe and the laws of its evolution and to appreciate the part played by **heredity, environment and education** in determining the ideas and ideals which go to construct the religious beliefs of individuals, are they becoming more open to accept **the contribution made by science** to our moral and religious philosophy.

The more enlightened element of all denominations now admits that science has in numerous instances unquestionably demonstrated that religious teachings have at times been wrong as to matters of fact. **Be that as it may,** man is a religious being, for he is by nature a truth seeker, and everyone must either have a philosophy of his own in reference to the questions of life or be creed-fettered by some fixed religious dogma, which seeks to mould him according to prescribed ideals.

At no time in the world's history were the rights of the individual so much appreciated as now. All religions are useful just in proportion **as they contribute to the development of the individual** in body and mind.

As long as religion appeals to the intellect and renders the individual conscious of his privilege of being a thinking, reasoning, responsible entity, with the power to exercise choice as to **what shall and what shall not** enter his life; as long as its promulgators inspire men and women **with high ideals** and point to sane, rational, sensible rules of conduct both for self-betterment and for the health of his fellow man; as long as it teaches him self-appreciation and altruism and its influence is for what is good and true and useful for human happiness and health and growth, **the beneficial influence of religion for the evolution of the individual** cannot be questioned.

The sublime faith that carries with it a conviction that is unshaken, that brings peace, eliminates fear, and makes life serene, **or a reasonable philosophy** that is entirely satisfactory to the individual in regard to his past evolution, present conduct, and future development, is as essential to the life, health and happiness of a rational human being as is food or water, exercise or sleep or air, congenial associates or other life essentials. **It is here that the mind takes refuge** in those problems that are forced upon the attention of all civilized races.

Yet, when the emotions have been wrought upon and the individual is led into that extreme state of mono-ideaism which exists in religious ecstacy with crying, shouting, or other manifestations of joy or grief, pleasure or hope, and he or she is no

longer under the guidance and control of reason, it can but be regarded **as psychical prostitution pure and simple.**

The psychical correlation between religious emotion and the animal passions is now recognized by all our ablest psychologists, neurologists and psychiatrists. **The erotic and religious feelings** are so closely associated that the step from the emotional religious enthusiast to the sexual prostitute is but a very short one.

As bearing upon this subject, Howard says: "Religious emotion springs from the animating power of the sexual nature, and through the emotion thus aroused we deify and worship the inspirational source of our spiritual longings."

Kraft-Ebing remarks: "How powerfully sensuality expresses itself in the histories of religious fanatics and in what revolting scenes, true orgies, the religious festivals of antiquity, no less than the meetings of certain sects in modern times, express themselves. . . . . **Owing to the correspondence in many points** between these two emotional states, it is clear that when they are very intense the one may take the place of the other, since every manifestation of one element of mental life also intensifies its associations."

The reader is aware that the more enlightened leaders of all religions now openly oppose any form of emotional excitement in religious services and regard it as a **deplorable relic of ancient barbarism. But, be that as it may,** it has been my experience to attend such meetings all over our country and the consciousness of the degrading influence of such meetings on innocent, impressible, and highly suggestible boys and girls, men and women,

who are the victims of these induced endemics of temporary emotional insanity, has been particularly painful and revolting to me.

Children, as well as men and women, who are not sufficiently educated to think for themselves upon these questions, are, when the emotions are stirred, suggestible in the highest degree, and any method of coercion which incites fear, plays upon the imagination and dethrones reason, is prostitution of body and mind. **One neurotic boy** of my knowledge remained in a subconscious state all night long and his nervous system never reacted from the shock or sense impressions of that experience. He was weak minded and hysterical ever afterward and finally became insane and died in the asylum. **A neurotic woman,** after having been subject to religious excitement for several days, began having cataleptic seizures and had kept this up constantly every day for two years, being all the while in a state of religious fervor, and was frequently visited by her minister, who would talk and pray with her, thus keeping up this morbid, psychoneurotic condition.

It has been my experience to be called in consultation to see two persons, ill with an acute disease, who died as a result of the effect of having been for several days subjected to the injurious sense impressions **produced by a fanatical, emotional revivalist.** The timely use of suggestion to drive back these perverted mental states and plant new sense impressions in their stead would, no doubt, have altered the results, but neither of these patients was amenable to treatment at the time I visited them.

The conviction of sin and fear of hell and the awfulness of the "Judgment Day" were impressed upon them until every organic function had been disturbed, they had been unable to sleep, food and medicine had not been assimilated, and they died of diseases from which under different conditions they should have made a speedy and sure recovery. **Such has been the experience of hundreds** of physicians of my acquaintance as a result of emotional religious excitement.

But aside from the danger that such pernicious influences exert upon life itself, the positive harm to the development and growth of body and mind is the worst. **To speak plainly,** the effect upon the entire individual is identical to that of excessive sexual intercourse and it is questionable if the results upon mind and body of sexual prostitution are not even less injurious.

Every intellectual state is accompanied by definite physical manifestations. The physical concomitants of such psychical states as where the individual is under the sway of emotional religious excitement are vasomotor phenomena, respiratory phenomena, and motor phenomena or phenomena of expression.

The vascular modifications that take place are felt in the form of arterial pulsations, heaviness and a sense of choking, all of which are usually ascribed to being "the power of the Holy Spirit" acting upon the individual. They all denote a state of tension of the organism and of concentration of effort. **Such emotion is contagious.** Mental states beget similar mental states in others who are so situated as to receive sense impressions from those thus affected. **The tension produced** upon the nervous system and the physical reaction to such experiences for several

days in succession leaves such individuals nervous and weak with all bodily functions disturbed. Sleep is hindered and they are often pale and indifferent to interest in all other things except religious matters.

We all realize that this is nothing more than a condition of hysteria, but such hysteria is contagious and when often repeated forms a habit, and such habits are positively injurious. To be exposed to such influences interferes with the growth of both mind and body of children, and the habit of having one's psychic life controlled and played upon by an emotional enthusiast, in the personality of an individual of the opposite sex, is positively destructive to the essential conditions of a happy marriage relation.

To educate an individual to be guided and controlled by emotion or passion in religious matters and expect him to exercise reason and judgment in reference to other phases of his life's conduct, would mean to teach him to act directly contrary to his religious teaching.

The over-expenditure of nervous energy from such emotional religious experiences and the habit of being psychically aroused by such experiences reduces the individual to a condition of mental and physical inertness. It is horrible to contemplate, but there are thousands of ardent female religious devotees whose psychic life is so dominated and controlled by their church executive or "spiritual adviser," that their husbands find no more place in their higher nature than a dog finds comfort upon the grave of his buried master.

This state of affairs reduces such marriage relations into nothing less than legalized prostitution. Whoever holds the attention of an individual, stirs his emotions, and directs his thoughts, governs his actions and controls his life both consciously and subconsciously; **and when married women are so dominated and controlled,** the higher social affiliations and more complete amalgamation of personalities between man and his wife are rendered impossible. **Such marriages, then,** are a fraud and a farce, and the result is unhappiness and nervousness, functional disorders and disease. **Such practices might be** excused in old maids and widows who are safely beyond the danger of ever getting married and who have **no ambition to attain in life;** but no growing young man or woman or wife or prospective mother should be exposed to their pernicious influences.

Adolescence, especially, should be kept free from an environment of religious fervor, which holds their constant attention and causes a useless expenditure of nervous energy to the neglect of the development of all other physical and mental attributes that should be cultivated by directing their lives into the normal, healthful, useful lines of thought and action.

The religious training of a great many individuals has but served to educate them into a psycho-neurotic disease, which practically unqualifies them for the duties and responsibilities of life.

To maintain a robust, vigorous state of health and physical well being while adhering to such religious practices is an absolute impossibility.

It is from this class of religious neurotics that Christian Science largely draws its membership and its dogma of negation and affirmation is only a suggestive means **to drive back morbid states of consciousness** produced by sense impressions made in times gone by and forgotten, and to replace these by conceptions, ideas, **sense impressions, or suggestions** that give rise to a new consciousness, to mental states that are **more pleasant, more hopeful, less emotional, more optimistic and cheerful,** and these react favorably upon the body. **With all its absurdity** Christian Science is a stepping stone, perhaps not an indispensable one, to the evolution and revision that is today taking place in the religious philosophies of the world. **To the man who is broad enough** and generous enough and wise enough to detect the kernel of psychological truth buried beneath its capsule of religious dogma, this cult serves as an illustration for an important lesson namely, that **the mind and the influence exerted upon it through religious worship plays an important role in the cause of disease and the maintenance of health.**

People are not to be blamed for their religious beliefs or habits of conduct in life. As a rule they are creatures of circumstance, fettered by **environment,** unfortunate **heredity,** and deficient **educational** advantages.

The clue to the situation was unconsciously admitted by a country clergyman in the South, who, in discussing the evolution that is taking place in religious ideals among the more enlightened centers of our country and the part that education exercises in shaping our religious beliefs, answered "Yes, but we care nothing about such ideals and education down here." **And so**

it is with everyone in reference to his philosophic and religious convictions. He instinctively feels that he is right from his viewpoint, and he is. His religion fills an essential need to his life and he has as much right to it as he has to life itself. And so has the individual who has acquired a broader perspective the same right to reject the false, worn out, and useless, and to interpret the problems of life for himself.

We are still only half civilized.

Ten million years of growth, evolution and development will not have remedied all the consequences of the ignorance that exists today.

Institutions, organizations and religions are a necessity. When they do not interfere with individual liberty and expression, they are useful. The majority of people are incapable of thinking and reasoning for themselves. They have not as yet acquired strength of intellect and knowledge of the universe sufficient to give them the confidence to take their lives into their own hands.

To them the power, strength, authority and privileges of the self-conscious ego are as much a stranger and as intangible and useless in the choice as to what shall govern and control their life, as if they never existed. Indeed, such a self-consciousness to them does not exist, for this quality of human personality is also developed according to the general laws of existence through heredity, environment and education.

However, individual responsibility cannot be evaded.

Men and women who know better and have evolved moral courage sufficient to give them the impulse to act up to their

convictions, **are impelled by immutable law under which they cannot decide** to do otherwise than press forward and onward and upward, and they are increasing their strength day by day according to the law of development by use.

We live in a new age and are confronted by new conditions. New opportunities are thrust upon us. We must live up to our privileges or take the consequences. We must turn opportunities to good account. We must each go our route. We can't live and do as any other individual in this world today or in any age has done.

The great need of the world is men and women to interpret life and its meaning in the light of modern education and enlightenment; such as will speak out aloud and tell the truth as the more enlightened people of this day see it, and who will not be intimidated by the bulwarks set in our way of progress by the **ignorance** and **superstition of ages past and gone.**

At least to us as physicians there is no other time but now, and no other place but here, and a billion of years will not make it otherwise.

CHAPTER XV.

CONSERVATION OF ENERGY.

EDUCATION AND CONTROL OF THE EMOTIONS.

BREATHING, RELAXATION, DIETETICS, ETC.

More power, strength and ability is a radical craving of the human being. Such cravings are as instinctive as the desire to live.

Each individual is endowed with latent potentialities or energy expressed in the millions of cells of his organism, according to their quality, and these he may use or abuse as he decides for himself.

How to create and conserve the highest expression of personality as represented by body and mind, in order that the greatest happiness may be maintained, is worthy of the serious consideration of every intelligent human being.

When we take stock of ourselves, we find that we have all the qualities of the lower animals, and others, besides, which are the distinguishing characteristics between human beings and the lower forms of intelligence. **Appetites, passions, emotions,** feelings, desires, and a consideration for others of its species, belong to the animals beneath us. **Man alone** of all the animal creation is capable of thinking and reasoning and of communicating his ideas to others **in spoken and written language.**

No rule of conduct can be pointed out as a guide as to the best methods for the individual to pursue in order that the highest degree of physical strength, intellectual development,

and moral character may be maintained. **That is the problem** that confronts every individual. **It is the problem of life** which each one must solve for himself; yet, how many there are who fail to live up to their privileges!

When we as physicians are brought face to face with the problem of treating disease we have but to reflect for a moment to see that the **real problem for the individual is** how to live.

The most fruitful cause of disease and weakness of body and mind lies in uncontrolled and misguided appetites, emotions, and passions, and a failure properly to conserve and direct our mental and physical energies into healthy channels of thought and conduct.

With the properly developed individual the intellectual functions and physiological processes are so under his control that he can by practice **direct any selected one as he chooses.** The true purpose of education is to teach the individual self-control and a just consideration for the welfare of others.

The sexual function, of the natural instincts, is second only to the instinct of self-preservation. In some individuals it is perhaps the strongest of all the bodily appetites and passions. **The healthy, vigorous glow of sexuality,** when not debased by sensuality, is the crowning glory of a man or woman. **We have but one Energy** and this is expressed by the individual in every manifestation of his life's conduct, whether physical, intellectual, or emotional in character.

Scott* has well said that **"purity is the crown of all real manliness,** and the vigorous and robust, who by repression of evil have preserved their sexual potency, make the best husbands

*Scott, The Sexual Instinct, E. B. Treat & Co.

and fathers, and they are the direct benefactors of the race by begetting progeny who are not predisposed to sexual violation and bodily and mental degeneracy."

The tendency of rational Medicine is getting more and more toward the prevention as well as the cure of disease, insanity and degeneracy in its numerous manifestations. **Educators and teachers** are at last awakening to the importance of defending ignorance and innocence **against morbid moral processes** as well as to protect them from smallpox and yellow fever; so the day is not remote when children will be taught in our common schools to regard the care and preservation of their bodies as paramount to their lessons in English grammar and arithmetic.

Monogamy will modify all excesses in the sexual line and **right thinking** will eliminate all habits which may be destructive to an individual or against the best interest of the community.

Aside from a condition of lowered vitality that is frequently maintained in both men and women by such indiscretions, emotional religious feelings, too much social excitement among enthusiastic, exuberant young people, over-eating, excessive chewing and smoking of tobacco, whisky and beer drinking, worry and over-anxiety about business, anger, envy, jealousy and fear, irregular habits of sleep, work and recreation, all contribute their quota to hold the individual in check and prevent the highest and best expression of individuality in body and mind.

A lady who had emerged from an excitable emotional religious revival, weak and nervous, after being sick for a day,

was anxious to return, and when I admonished her of the danger of such dissipation, and remarked that death itself was not infrequent as a result of such indiscretions, she answered suavely that "it would be a lovely way to die."

In the same spirit another patient whom I advised to abandon the use of tobacco and whisky if he expected to get well, replied that he would rather not live if he had to give them up; that he had reached the age when his sexual powers had failed, and he now felt that these offered all that went to make life worth while.

It is hard to realize, until one stops to consider this subject, in what complete slavery many human beings are held by their appetites and uncontrolled emotions and passions.

A country parson once sent for me, and very seriously and confidentially explained that the physicians of his town did not understand his case. That he had for years suffered so much with indigestion until he was unable to do mental work, and, though he "loved his work and was completely in the hands of the Lord," that it troubled him to be unable to prepare sermons that would hold the people. He was six feet high and weighed two hundred and eighty pounds. After he had related his tale of woe, I informed him that the external evidence in his case did not coincide with his interpretation; that instead of suffering with indigestion he gave every evidence of digesting and assimilating too much food. **Then turning to his wife** I asked how much he ate for breakfast as compared with the other members of the family, and she answered, as much as herself and their four children combined. **I reasoned with him** and

explained how it was impossible for his stomach and his brain each to perform the highest function at the same time, and outlined a reasonable diet, advised that he walk ten miles a day and cut his own wood, work in his garden, and take such other physical exercise as would reduce his weight. **He took my advice kindly,** and two weeks afterwards informed me that he felt like a new man. He had been so completely occupied in getting individuals to " save their souls," that he had forgotten the present salvation of his own character sufficient to control his bodily appetites.

I was once introduced to an aged physician, then ninty-one years old, who had just returned from a six-mile ride on horseback on a visit to a patient in the country. I inquired why he did not leave such trips to "the boys " in the profession, pointing to two physicians who were themselves between sixty and seventy years old. I shall never forget his answer. He died of pneumonia several months afterwards, but that answer of his contained a fine lecture on psycho-therapeutics. **His reply was: " I don't want to die.** Do you not know that as long as a man is at work, he is thinking, and that when he is working and thinking, he is using his brain cells, and that the brain cells kept in constant use give strength to every part of his body ? "

For sixty-five years, this physician, old Dr. Smith, of Oxford, Mississippi, had kept in harness, frequently making trips on horseback for sixty miles in the early part of his professional career, and he furnished a good illustration of the salutary effect of continuous exercise and useful employment.

The only safe way to control our emotions, appetites, and passions, is to direct our energies into channels of wholesome and useful effort, whether it be physical or mental effort. The result is strengthening to both mind and body, provided it is done cheerfully and with a purpose.

The emotional part of our nature, when guided by reason, is expressed in enthusiasm, a quality which is essential to success in any line of effort. **Be it man or woman,** the continuous and persistent pursuit of some steady work or useful employment will react as health and strength-producing factors to both mind and body. **This very effort** conserves our energy, guides and controls the emotions, and cultivates all the positive qualities of human character. **The proficiency** which comes from continuous persistent effort achieves a self-reliance that eradicates fear.

Worry is only our own recognition of our inadequacy or or inability to be equal to the exigencies of life. It shows a lack of self-reliance, without which man is but the plaything of chance, a puppet of circumstances.

Envy and anger and jealousy are all characteristics of weakness and incompetency. Such negative qualities can find no place in the life and character of a real man or woman.

There is a retroactive degeneracy of wealth which, as history has shown, proves the destroyer of the idle, the proud, and the self-conceited.

The sooner every human being can learn that the real elements that create health and strength and happiness and success in life are inherent within him, and that reason should

be the guiding star by which he should direct and control and develop and use the potentialities within his own organism, the sooner will he realize that upon him alone depends the responsibility of so living that he can maintain sufficient resistive power in the cells of his organism for health to become a habit and happiness and success the rule of his life.

We have only a few medicines that can be relied upon in their application to the treatment of disease, and in some instances it is really remarkable how well people get along without any medicine at all.

In one little city of 25,000 inhabitants, the physicians informed me that a non-medical practitioner in that town was doing more work than any two physicians in the place. He had taught school for a good many years, and had gained quite a fund of general information in regard to psycho-therapeutics, dietetics, hydro-therapy, massage, exercise, etc., which, coupled with a good personality, enabled him to practise with remarkable success.

Now, I am not a therapeutic nihilist. We should use medicine when indicated, and there are conditions in which is it absolutely indispensable, but in the great majority of cases that come to us for aid, we should display **more confidence in our patient's brain plasm** and in the recuperative powers inherent in the cells of his organism under proper conditions, to re-establish a condition of health.

Without the co-operation of the patient, it matters not what be our therapeutic measures, we are handicapped very seriously. It is not what we do for the patient with materia

medica agencies that is the greatest factor in therapeutics, but the environment which we create for him and what we get him perhaps unconsciously to do for himself. **If his brain cells do not respond** to the sense impressions made upon them so as to get him to act upon and execute our ideas both consciously and sub-consciously, then may we expect very little benefit to be derived from the administration of medicine. **It is what he eats and what he drinks, how he acts and the way he thinks,** together with breathing and relaxation, fresh air, pure water, work and sunshine, that are the real helps to get a sick man well.

Thousands of the ablest physicians place little or no confidence in more than a few medicines, aside from the confidence that the patient has in their efficacy. **Is it not time** that we should deal with our patients squarely and honestly, and, while giving medicine when indicated, either for its physiological or psychological effects, let them know that the real source of health and happiness depends upon their own control and direction of their conscious and unconscious psychic activities into normal, healthful lines of thought and conduct. **Where an individual needs such advice,** and the majority of them do, I should deem myself untrue as his physician and false to my Hippocratic oath, did I not express my honest convictions relative to the real elements that contribute to his health and well being.

Thousands of American people to-day are magnificent examples of what intelligent, systematic, physical exercise can do in the way of developing a vigorous, robust, healthy body.

A large percentage of our most successful physicians are physical athletes as the result of intelligent physical training.

As yet not one person out of five knows how to breathe, or realizes that sufficient oxygen taken into his lungs from the inspired air is as important as the food that he eats.

Water, pure, wholesome water, as a functional stimulant, a toxine eliminant and health-producing agent has not occupied the place it deserves in our therapeutic armamentarium or in the appreciation of the people, whose privilege it is to use it without our advice.

Most of our people still overtax their nervous systems with an excess of meats, as an article of diet, and thus maintain a lowered power of both mind and body on account of such indiscretions and excesses. **The tests at Yale University,** made by Professor Irving Fisher, have proved beyond all question that " a low proteid, non-flesh or nearly non-flesh dietary " is conducive to a greater mental and physical endurance than the ordinary American diet.

The use of the corset as a fruitful source of disease yet needs to be impressed upon the minds of our women.

Intemperance or lack of self-control and the use of reason in eating, in dress and business activities, and religious worship, and sexual matters, and emotions of all kinds, and passions of every description, should all be kept in mind by the physician who intends to make such suggestions as will redound to the greatest benefit of his patients. **Self-control is** humanity's greatest, highest, noblest achievement.

CHAPTER XVI.

ROUGHING-IT AS A MEANS OF HEALTH.

Disease is a condition where the cells of a part or of the entire organism do not properly perform their function. At any rate, it denotes an absence of health. These are only relative terms, for what might be a condition of reasonably good health for one individual would be so far below the normal standard of another as to be considered disease for him.

A problem that confronts every human being is how to maintain the highest possible degree of resistive power in the cells of his organism so as to render them invulnerable to pathogenic germs and other etiological factors of disease. **This can not always** be accomplished by tonics, reconstructive agents, etc. In many instances it is simply a question of getting the individual to conform to those conditions and habits of life which bring an increased degree of resistive power to the cells of his organism as a consequence. **Such habits can often** be brought about as the result of an idea put strongly into the brain plasm of your patient. **Before you can succeed** in putting such an idea sufficiently strong to get your patient to act upon it so as to change his habits of thought and conduct, you must believe in the efficacy of the means to secure the desired end. **Confidence begets confidence** and conviction creates conviction; courage begets courage and health begets health.

So, if a physician is weak, discouraged and tenderfooted, before he can get others to act upon an idea, either consciously or subconsciously, he must get right himself.

To bring about this end, try "roughing-it" as a means of health, and get your patients to do likewise.

The finest reconstructive agent at our command is an idea conveyed to your patient that will create hope, expectancy, confidence and optimism. **All these encourage anabolism** or constructive metamorphosis, and this is doubly true when it moves one out **into the sunshine and fresh air** and **enforces exercise** and deep breathing, resulting in sound sleep, good appetite, and increased digestion and assimilation. **It means new blood** for the patient and all this contributes to health.

Along with this comes a rest from the routine path of life, the dropping of business cares and perplexities, and a chance to catch something of the inspiration that comes from associating with birds and wild flowers, trees and rocks and running streams. **The psychic and physical effect** for the good of the individual of all such measures cannot be overestimated.

We are told that one death out of ten in the world today is the result of tuberculosis. It is not so. **The people who die** infected with tubercle bacilli do so because they do not live so as to maintain that high degree of resistive power to enable the cells of their organism to withstand the onslaught of this pathogenic enemy.

In offices and street cars, in places of business and on the street, we in cities are exposed to the tubercle infection every day of our lives. **We do not contract the disease** because we are

alive enough to resist its invasion. **The factors of disease** are here and ever will be. It is up to us to learn how to live.

No better illustration of the value of roughing it can be cited than where thousands and thousands of individuals with this disease are yearly going to the high altitudes along the range of the Rockies and dropping all home comforts, having the will and courage to face hardships in the West, living out of doors in open tents, and in this way making the fight for their lives. **The very decision to do** that which they believe will result in their recovery is the important essential which, favored by a dry high altitude and the conditions for living in the open air and sunshine, and encouraged by the optimism and cheerfulness of those who have been in that section long enough to have dropped the title of "tenderfoot," brings about a restoration of health.

Life is a struggle with us all. **In order to live** we must dare to be. We need sufficient resistive power in the cells of our organism to combat the etiological factors of disease, and this **can only be secured** by conforming to the requirements for creating and maintaining that high standard of healthfulness that will secure this quality.

In all classes of practice, medicine is only an aid. With its assistance the individual's chances of recovery, when sick, depend upon the **natural recuperative powers** of the cells of his organism.

In thousands of instances during warfare individuals have left their homes of comfort and luxurious ease and for years have endured the hardships of camp life and the stress of battle, on scanty food and insufficient bedding without shelter, only to re-

turn after the campaign strong and robust and in a perfect state of health.

During the cowboy days many young men, reared in wealth and affluence, went as physical weaklings to the Western plains and astride a broncho followed a herd of cattle and endured the hardships of camp life and simple diet, until they were rewarded with health and vigor of mind and body.

The very process of learning to be content with little to make one comfortable and satisfied with extemporized substitutes, cultivates a mental and physical stoicism which, as a means of health, is hard to overestimate.

We watch with interest a game of baseball or football on the hottest day of summer and wonder how the participants can so ignore the heat and enjoy such sport; such "roughing-it" brings its reward and produces physical athletes.

At a temperature of 110 degrees in the shade I watched a gang of men working for hours and hours in the hot sun engaged in laborious manual labor with pick and shovel. This acquired physical resistance came "by roughing-it," and the men were healthy and happy.

A month after the earthquake of San Francisco, when a hundred thousand people were in improvised tents and on plain, coarse food, the health of that city was officially reported as being better than at any time in its history. Neurasthenics who must have a cup of coffee with snowflake crackers in bed before rising in the morning were, after one month of "roughing-it," enjoying a breakfast of onions and beans.

The health and vigor that rewarded the early settlers in the pioneer days of our country when they were compelled to labor hard, live simply and have but little, also has its lesson.

To the thoughtful observer it is plain that our artificial methods of living at the present time are not conducive to the highest development of manhood and womanhood.

When education interferes with physical development it strikes a weakening blow at the quality of brain plasm of the individual, an element that must be kept at a high standard to attain the best results in mind and body building.

It has often been observed that the most successful men in all professions, and in all lines of business, in our large cities, have been, and are, those who were reared in the less populous towns and rural districts, where those natural conditions of simple living, fresh air, pure water and sunshine, quiet surroundings and wholesome food, exercise and employment, furnished the enviornment under which the highest standard of physical development could be produced. **Such conditions favored the growth** and development of a quality of brain plasm that manifested itself in the facility with which the individual was enabled to withstand the arduous duties and responsibilities amid the more complex environment of city life.

The boy reared in the fields, well acquainted with the woods and familiar with the chop-ax and the wood pile, thought he was having a hard time; but we know better now.

The country girl that rides horseback to school, carries a cold lunch in a bucket, and grows up among the birds and flowers, with cheeks painted by fresh air and sunshine, has a mental and

physical equipment for life that far surpasses the accomplishments of her more delicately formed city sister. **Let this be supplemented** with a liberal education and she is prepared to withstand the exigencies of life under any and all conditions.

"Yes," said one physician, "granting that all you say about the value of physiological and mental therapeutics be true, if we put the laity in possession of such knowledge, we physicians are likely to be out of a job."

To entertain for one moment such a selfish idea or to give expression to such sentiments is not in accord with the spirit that actuates the leaders of our high and noble profession.

No better illustration of the absolute absurdity of the idea that any one therapeutic resource in the form of psycho-therapeutics disguised as Christian Science or osteopathy, or any physical culture or dietetic fad could ever supplant the rational work of the physician can be made than by quoting here from that excellent article appearing in the **American Monthly Review of Reviews** entilted, **"The Doctor in the Public Schools,"** by **Dr. John Cronin,** of the health department of the City of New York.

No better illustration, also, of the influence exerted **by the body upon the mind** and of the criminal neglect that fanatics are likely to bring upon the children of our country, by failure to have proper medical attention given for the correction of physical defects, could be presented than are made plain by the facts brought out in this report.

After relating the history of the movement for the inspection of children in the public schools as instituted by the board of health and relating the facts showing the necessity for a more

thorough physical examination of children in the schools, Dr. Cronin says:

"Of 99,240 children examined in the schools of the Borough of Manhattan from March 27, 1905, to September 29, 1906, 65,741—or about 65 per cent.—needed some form of medical treatment. Of those 99,240 children, 30 per cent. (30,958) required correction of defects of sight, in most cases by eye-glasses. A still larger percentage (39,778) needed attention to their teeth. There were 38,273 children with swollen gland, in the neck, indicating some present or past trouble in the throat, noses ear, or some abnormal constitutional condition. Enlarged tonsils, with their baneful effects, including liability to tonsilitis and diptheria, were found in 18,131 children. About 10 per cent. of all the children examined (9850) were found to have adenoid growths in their throats—a condition which predisposes to affections of the ears, the nose and the lungs, and which interferes most seriously with the child's general health and mental development. Heart disease was found in 1659 children; disease of the lungs in 1039, and deformities of the bodies or limbs in 2347. Of the children thus far examined 2476 have been found mentally deficient; but probably the percentage of such children in our schools is slightly greater, as the figures thus far quoted include largely the primary grades, in which the mental development of the children is not so easily judged as in the upper classes. . . . . .

"But perhaps the most striking results in the way of physical and mental improvements have been noted in the children who have adenoid growths or large tonsils removed. The amazing change which these children have undergone can scarcely be believed unless actually witnessed. From dullards, many of them have become the brightest among their fellows, after the operation. . . . . .

"It has been shown that 95 per cent. of 'backward children' and of mentally deficient children have physical defects which can be remedied, thus improving their mentality as well as their physical health. According to the City Superintendent of Schools, 40 per cent. of the children of the schools of New York are below the grades in which they should be according to their ages. The Department of Health has found that 2 per cent. of all the children thus far examined were mentally deficient, and in nearly all these cases adenoid growths, defects of vision, or other remedial disabilities existed. In the special classes for defectives in Public School 110, 95 per cent. had adenoid growths in the throats. . . .

"Moral obliquity, of which truancy is the first manifestation in school life, goes hand in hand with physical defects. Thus, among eighty-three truants examined by the Department of Health in the Special Truant School in this city, 87 per cent. were found to have physical defects, in most cases of a remedial character. Truancy, and its kindred ills—the 'street habit,' and the 'gang habit'—lead to crime unless speedily checked. The records of the Children's Court in New York and of the similar court in Chicago showed that nearly all the youthful criminals that were brought to these courts were truants, and, what is more, that 85 per cent. of these children were found physically defective. . . . . .

"To sum up, we may say that we have shown beyond peradventure that physical defects exist in about 60 per cent. of all school children in New York; that in most cases these defects are remediable by proper treatment, and that the early discovery of these defects is the prime factor in the maintenance of the health of the school children and in enabling them to pursue their studies.

"We have shown, furthermore, that backward, mentally deficient, and truant children, can be vastly improved by the early recognition of

physical infirmities which underlie their mental or moral defects, and that by appropriate treatment, if applied early enough, we can save these children from illiteracy, from drudgery in factories at small wages, or from an almost inevitable criminal career.

"In view of these facts, what can be more important than a systematic individual examination of every school child at stated periods, and what can be of more lasting benefit that the early application of the proper treatment in all cases in which physical defects are found? . . .

The facts, however, brought out in this report show also the ill results of an environment that does not furnish fresh air and sunshine, pure food and good water, and a mental quietude that is conducive to sound sleep and a healthy body.

That such ill conditions exist is no fault of the medical profession, whose work it is to meet conditions as it finds them.

Disease usually attacks the most vulnerable point, and where a low state of physical resistance is maintained, it is manifested in numerous ways.

Correction and treatment of physical defects in children and adults by all means should not be overlooked when we are brought face to face with such conditions, **but what is of far greater importance** is that people be so environed that health and vigor of mind and body would be the natural consequence of such an existence.

We all have noticed the benefit resulting in health and strength to a city-bred boy or girl who had spent a short time "roughing-it" in a country home.

CHAPTER XVII.

ARE ALL SPECIALISTS EGOTISTS?

Egotism and altruism are the distinguishing characteristics of an enlightened mind. An individual with the first quality only, however, without the second to balance it, is converted into a character that would be more aptly described by some other adjective. **Such men are everywhere,** in all professions and avocations of life. They are those who have acquired a one-pointed view of seeing things. **They follow the path illumined** by the light of a narrow intellect so long until their faculties for any other conception or interpretation become dwarfed and useless.

The tendency of the human mind is to run in channels carved out, as it were, in the brain plasm by sense impressions most constantly and frequently playing upon it. **The reflex of these impressions** is what gives rise to every individual's peculiar way of thinking and reasoning. So that a man who continually looks at any problem, be it that of a physician, facing the complexities of disease with all its numerous manifestations, or any other individual facing any problem **from a restricted viewpoint,** is liable to be mistaken.

Specialism in medicine, from the very nature of things, is a necessity. It has come to be regarded as synonymous with proficiency, and is, as it ought to be, here to stay. Furthermore the men that compose the rank and file of our specialists are for the most part, broad-minded and well educated physicians.

The specialist's association with the general practitioner and the men who follow other special lines of work than his own is usually a safeguard against his acquiring a narrow way of interpreting the symptoms of disease. Much of his work is referred to him by his colleagues, who, in some degree, feel the responsibility as sponsor for his treatment. **He is usually a man** who has followed the law of adaptation and his particular branch of medicine is chosen in view of special qualifications and fitness, and he continues his specialty according to the law of the "survival of the fittest."

Granting all this, and much more that could be said in his favor, there is a strong tendency for the physician to exaggerate the importance of his special line of work as a contributing factor to the welfare and happiness of the human race. **His very proficiency** and success and belief in himself and his methods, all combined, have a tendency to produce an unconscious temporary psychic beneficial result to his patient, as an accompaniment of other special treatment; and frequently a relapse of the patient into ill health follows, indicating that an important element in the case had been overlooked. **Finally,** the patient, usually a woman, seeks another specialist, on an entirely different line, who discovers what he regards to be the real source of her illness, and she is again temporarily benefited. **The results prove** that this physician also was correct, but the patient has added to her consciousness an increased awareness of her complications.

After a third, or perhaps a fourth, physician, each of a different specialty, has conscientiously and correctly treated

the patient, she has been unconsciously suggested into a state of invalidism.

She then falls into the hands of some non-medical system of treatment, a Christian Scientist for example, where she becomes educated to disregard the medical profession and for the privilege of outpouring her abuse upon all physicians, she unconsciously adopts a stoicism that enables her to exist in a reasonably fair state of health, while she daily declares that it is all an "error of mortal mind." **The very egotism of her leaders** and the self-assertiveness of her new environment gives her the psychic stimulation and encouragement to tolerate her existing physical disabilities, which, in reality, are improved because she ceases to give them attention. **Her morbid self-analysis,** with its despondency and fear, has been replaced by a positive antagonistic attitude to the medical profession, and she becomes so preoccupied in deriding physicians that she forgets her physical disabilities much to her betterment.

It has been my experience to find many such cases as outlined in the above description. Just such a lady once sought my advice, luckily having visited only two physicians. **Her neurotic symptoms,** insomnia, headaches, indigestion, etc., were the natural accompaniments of a pronounced error of refraction and a catarrhal endocervicitis.

After proper glasses had been prescribed by a competent oculist and her endocervicitis appropriately treated, it was an easy matter to secure habits of plentiful and refreshing sleep by suggestion, following which was a good appetite and

digestion, improved nutrition, a relief of all neurotic symptoms, and a rapid return to health.

Neither the " neurasthenia " of the neurologist, the " subacute gastritis " of the stomach specialist, the " catarrhal endocervicitis " of the gynecologist, nor the " astigmatic error of refraction " of the oculist, treated alone, as applying to this case, could have resulted in the relief of that patient. **Furthermore,** she could have had the benefit of all the specialists in the medical profession, and if she were under a **religious environment** that maintained a psychoneurotic condition, with its disastrous consequences to the normal physiological processes of the body, her reduced physical resistance thus maintained would have precluded the possibility of perfect health under any circumstances.

The egotism of the specialist, then, becomes a dangerous and abused quality of human personality the very moment he unduly exaggerates the importance of his specialty, to the neglect of other lines of sane, sensible, rational therapeutic measures, be they surgical, gynecological, medicinal, environmental, hygienic, dietetic, psychologic, mechanical and physical or physiological.

No one is more prone to commit this unpardonable sin against his profession than the psychotherapeutic fanatic, who is also in evidence, and such specimens of narrowness and bigotry have done much to retard the progress of this branch of therapeutics within the past twenty years.

Let us remember that we are human beings, as are, also, our patients; that we are physicians as well as specialists, and

as physicians let us acquire a broad and generous perspective of our patient and his welfare, and of his and our relations to others, and not unduly exaggerate our importance. **No man has a right** to expect the support of his colleagues in a specialty who is not first a well qualified, all-round physician.

We should be prepared to give our patients the benefit of all that modern professional skill and knowledge offers, and should have **the courage to manifest the egotism and altruism** to insist upon his or her conformity to all conditions and means that contribute to health, and then the people would not so often find it necessary to resort to measures outside of the medical profession, for relief that we fail to give.

Man as a whole, a being both physical and mental, composed of qualities designated as mind and body, must be taken into consideration.

CHAPTER XVIII.

PERSONALITY AS A FACTOR IN THERAPEUTICS.

The personality of a physician is an important asset in the makeup of his professional equipment.

The achievement of personality is the goal sought by everyone beginning the study of medicine; and everything pertaining to medical thought, colleges, books, hospitals, clinics, operations, laboratories, dissecting rooms, class associates, quiz masters, instructors and professors, all combined, furnish the environmental and educational factors which collectively go to convert the aspirant into the type of *genus hominis* known as a physician.

Aside from his scientific medical training, the personality of a physician is the greatest factor in the make-up of his professional armamentarium. **So much so is this true** that we often hear the expression that "the physician is born, not made." **Such an expression** usually implies that there is an inner quality of personality that manifests itself in the dealing of a physician with his patients, that does not exist equally in all men equally trained in professional knowledge. **There seems to be an inner spring** or quality of character that counts when such men are put to the test in the office, or at the bedside, in daily intercourse with others, on any and all occasions, which is a *sine qua non* to the successful practice of medicine.

There is in every one a quality of personality that either attracts or repels others. It is not necessarily an accompaniment of any special type or physique or nervous organization.

It is found in men of small build and of neurotic type as well as in those that are robust, phlegmatic and heavy. **Such men frequently make serious blunders** in their professional work, but still they hold the people.

Individuals sometimes wait one, two, or even three days for a physician to sober up from a debauch and go for him with their own conveyance and assist him to the bedside of a sick wife or child, and declare that they would prefer him drunk to any other physician sober. This has been an occurrence in a city whose medical profession compares favorably to that of a town of equal size anywhere.

It has been a matter of personal experience, in my own work among the medical profession, that I have frequently grasped the hand of a stranger and instantly felt that I had found a warm personal friend before we had exchanged any more than a mere formal greeting. **On the other hand,** I have frequently felt so repulsed, at the first glance of a physician, that I refused to acknowledge him as a man whom I wished to meet.

Upon one occasion I called upon a physician of high professional attainment, whose conduct, when I approached him, was discourteous in the extreme. I looked him squarely in the face for a moment, and extended my hand, saying, in a quiet monotone, " good-bye, doctor." The effect of this upon him needs no comment. He shook hands with me, but learned a lesson. **In his reception room** he had but one patient and that one appeared to be an old stand-by. This was no surprise to

me, for that physician had given me a taste of his quality, and I never cared to see him again, and so it was with his patients.

From this office I went to see another physician, in the same specialty, who was courteous and human, really showing me more deference than I felt that I deserved. He had won a high place in the esteem of his colleagues by hard work in his home city, and his office was full of patients. **The treatment accorded a stranger** by that physician was a sample of the quality of the personality of the man, and such a quality as the people liked, and he is doing a great work.

Invariably those of the medical profession who are competent men and who possess this happy streak of personality above illustrated, are making a success of their work.

There is a lesson for us as physicians in the following verse:

"There are loyal hearts, there are spirits brave,
There are souls that are pure and true;
Then give to the world the best you have,
And the best will come to you.
Give love, and love to your heart will flow,
A strength in your utmost need;
Have faith, and a score of hearts will show
Their faith in your word and deed."

A little display of those qualities typified by the great religious reformer about two thousand years ago, kindness, sincerity, sympathy, earnestness, fearlessness, bravery, magnanimity and altruism, is an inestimable element in the personality of the physician. **It helps to get control of people,** not by force, and better enables him to put them in possession of themselves.

Here is the clue to the explanation of that indefinable psychic quality that the most successful physicians carry with them which proves a power in therapeutics; and this is manifested all unconsciously by him in every move of his life. **It begets the confidence and trust** of his patient and the respect and co-operation that is a most essential factor in the successful treatment of any disease.

Especially is this quality in the physician necessary in the treatment of enlightened and self-respecting people. It begets a reciprocation of that respect which such people feel is due them. **They positively refuse** to be driven, but it is only an evidence of their high intelligence when they are willing to be led for their own good by the skillful direction of a cultured, competent, conscientious physician.

A sensible display of tact and diplomacy will often enable a physician to win the confidence of a patient, and thus secure the co-operation so essentially necessary for the best results, when the being too blunt and abrupt would render him utterly helpless.

To see one physician so manage a little fellow as to get him to submit to the skillful dilatation and treatment of a suppurative dacryocystitis with hardly a whimper, by his firmness and kindness and tactful persuasion where another would become nervous and excited and spend a much longer time in accomplishing this result, his patient crying vehemently and suffering a needless amount of pain on account of his resistance, is an illustration of what personality means in a certain class of work.

It is a great help to a physician to be able to get hold of people and use them to help themselves to get well. We all help or hinder the recovery of our patients, far more than many realize, by the way we deal with them. We unconsciously use suggestive therapeutics at every step in our routine work.

People buy goods of the merchant they like, the groceryman they like, the dairyman they like. In all trades this personal factor is taken into account. A dry goods clerk brings a better price because people like him, he knows how to deal with people and to help them to suit themselves in their purchases; but more than in any other department of life does the personality of the physician count in helping people to get well. **A patient cannot get into your office** and walk out without your personality having made some mark upon him. **There are people** in whose presence you are always at your very best, and for whom you can render the best professional service.

It is a recognized psychological law that we become like those whom we habitually admire. Thus we become a part of all with whom we have associated during our existence. **In all of our experience with literature** and personal association, this law continually operates, so that all men are reproductions of other men.

In all sections of the country are neurologists, who, from constant association with a certain class of patients, seem to have become the living embodiment of all the objectionable, mental and physical characteristics of their patients. **A patient who had twice** been to see a physician of that type, remarked that he felt worse after each visit, and did not care to return again.

Another neurologist who was himself the personification of physical strength and mental vigor and optimism, remarked to me that he never felt as though he had done his duty unless he sent his patient out of his office feeling better for having come to see him. It is needless to remark that he is one of the most successful men in his specialty in the profession to-day.

The reader will pardon me if I seem critical or personal in my remarks in this chapter, but the importance of the subject at hand is such that I should deem my effort futile did I not drive home the point under consideration.

We all have our short-comings. Day by day do I have added to my consciousness an increased awareness of my own deficiences as compared to the knowledge and competency of some of my colleagues with whom I have been privileged to associate. Only my experience and the results obtained by careful observation of the personal factor in therapeutics and the encouragement of physicians who have also personally tested these methods, would give me the courage to express my honest convictions at all hazards.

I fully realize that the hard knocks and criticism that may be fired at me will only serve to educate the profession in the sane, rational use of the measures advocated, and if such be the case, my efforts will not have been in vain.

It is a great thing to be able to make a hair-splitting diagnosis, the correctness of which is infallible, and I shall unceasingly strive to attain such proficiency.

It may also be a great satisfaction, and it is of unquestionable benefit to the physician who can do it, to give a minute and

detailed delineation and description of the pathology of a disease to the satisfaction of his professional associates, but such an elucidation is never of value to the patient.

Physicians themselves become the easy victims of any disease as soon as they become conscious of the seriousness and gravity of the diagnosis rendered by their colleagues in attendance. **Their very knowledge of its etiology** and pathology renders them unduly self-conscious of their condition, and such a self-consciousness gives rise to morbid mental states that inhibit the normal physiological processes, prevent sleep, and seriously retard recovery.

When I see a physician sick and half dozen of his learned colleagues lined up around him, all rendering him more self-conscious of the seriousness of his condition, I can but wish that only one of them had been called and that he possessed those qualities of personality that, **in spite of the physician's knowledge of pathology,** could drive back those existing morbid sense impressions and substitute in their stead mental states that would enable him to put up a more creditable fight. **If the life** of a physician is worth anything the end would justify the means. **So while giving due appreciation** to scientific professional knowledge and training in pathology and diagnosis, **what is of far greater importance** is, that we so use our knowledge as to help our patients to get well.

Every visit of the physician is an opportunity to help accomplish such a result, and here is where the personality of the physician is often detrimental or helpful to the recovery of the patient. **The very self-consciousness** induced by a

physician at his visits, and the mental states which follow in consequence of such an induced self-consciousness, are the deciding factors for the good or harm of the patient. **The influence of personality** is contagious. We set up mental states in others around our patients that prove helpful or harmful in the sick room.

Out in New Mexico a young man walked out of a physician's office looking downcast and dejected, with lips tightly closed and with jerky inspirations. "A lunger up against it good and hard," is the way they refer to such patients out there.

That night I lectured to a class of physicians and the next day that patient went out of the same office with a smile on his face, and a bright animated expression, having taken the first step towards recovery, as the result of sense impressions or suggestions strongly made upon his brain cortex by his physician. **He ate more that day,** slept well that night, and reported that he had coughed but little, was not so nervous, had enjoyed his breakfast, and felt stronger. **All because his physician** had the personality to exercise the **egotism and altruism** to look him squarely in the face after his examination and say to him, "I have some good news to tell you. You are much better to-day. Already a marked improvement has taken place in your condition, but you will be very much better by to-morrow. You will enjoy your food to-day, have a good digestion, sleep well to-night, and improve every day from now on."

Physicians themselves frequently have invalid wives, whose invalidism is maintained in consequence of the constant association of a husband whose personality depresses them. **The**

affection displayed by such men for their wives may be beautiful to contemplate, but the accompanying emotional, sentimental sympathy, is weakening in the extreme.

Reader, if you happen to be of that type of individual, get cured of your miserable psychoneurotic disease, and don't live as a parasite infecting the lives of those with whom you associate. **My prescription for you** is, to associate and amalgamate with the wide-awake element of the medical profession who constitute the upper ten per cent. of our ranks. **Sages, poets and philosophers** of all ages have repeated this message to the world, that men and women make men and women.

If there be anything of value in these expressions, that I so feebly echo here, they are but the reflex of impressions that association with other personalities has left upon my cerebral cortex.

If the quality of my brain plasm were of higher standard, and my previous environmental and educational advantages had been more propitious, my opportunities would have borne better fruit.

We all have our capacity, and, under equal opportunities, we can only react upon sense impressions or suggestions in proportion to our qualifications.

Whatever be our deficiencies as a result of heredity, environment, and education, each of us can give our patients of our highest, truest, and best self, as an aid to their recovery.

Some men bring a reproach upon the profession on account of a failure to exhibit those character qualities which alone constitute the highest type of professional personality and

manhood. **By the correct use** of your personality as a factor in therapeutics, you help people to help themselves. But there are instances when you advise a nervous patient who is suffering with insomnia and a train of functional disorders, to relax and practice deep rhythmical breathing, and to concentrate his mind on sleep as a means of self-help, and **the neurotic patient says, "I can't." The stability of his nerve and brain plasm** is below par, and he lacks the will power and determination to execute your advice or simple suggestions.

"Then I will relieve that uncontrollable nervousness for you, so that you can lie here and let this medicine have its effect." **The patient believes in the medicine,** but not in himself. Only a placebo is used, but by kindness, firmness and persuasion, I got my patient to relax and exercise that self-control which he believed that he was incapable of doing. **By the aid of my suggestions** he easily goes into the hypnotic or suggestive state. **Then I plant new ideas, impressions,** and feelings upon his brain plasm, and he awakes from the treatment with a new element added to his consciousness. He now feels that he can relax, breathe deeply and rhythmically, and go to sleep. **In the waking state** I reinforce these suggestions.

"That treatment has greatly benefited you. You can relax and will sleep well to-night. You will always feel better after this."

A new quality of self-hood has been added to that patient's personality. Brain cells have been encouraged and persuaded into action. What I did for him was in a spirit of kindness

and for his best interest, and he appreciates it as such. **He leaves my presence in gratitude** and feels that I am his friend.

The fear that some physicians have that people will object to the employment of these methods is a self-confessed weakness. They are too proud to express a favorable opinion. Fear never accomplished anything for the good of the physician or his patient. Some of the best friends I have in the world to-day were those made in my efforts to get them to control themselves, who took my suggestions given either consciously or sub-consciously, and through such aid learned to rely upon themselves.

In the employment of suggestion, both with and without hypnotism, you are only helping your patient to help himself. Yet many physicians will denounce and ridicule it and go on filling neurotic patients with such medicines as lessen in every way the patient's self-reliance, making the patient absolutely dependent upon them.

A man who practices medicine in that way may make money, but he also encourages the business of the undertaker. He can only be excused upon the ground of ignorance.

CHAPTER XIX.

THE ABUSE OF PERSONALITY.

In order to make myself understood, I will give you an illustration of how personality is abused in the practice of medicine, and the picture here presented is an apt illustration of the conduct of many of the general practitioners, who do not take into consideration the psychological factor in therapeutics.

All observing individuals have noticed that in every locality there are physicians who have more "very sick" patients, in proportion to their patronage than others. **That the personality of a physician** is frequently the prime factor in producing these "very sick patients" is beyond question.

Here is an illustration of the usual conduct pursued by such men in the treatment of an ordinary case of pneumonia, a disease in which the correct use, or abuse, of the personality of the attending physician, **more than in any other acute disease,** determines the recovery or non-recovery of a patient.

"Give this medicine very carefully, and watch her closely until I see her again. I will call this evening."

True to his promise he is punctual in fulfilling his appointment, much to the satisfaction of the family, who anxiously await his coming. **During the day** the sick mother has grown more nervous, her temperature is higher, her pulse rate faster. She is by this time over-anxious about her condition, and this in turn has made her family extremely anxious about her.

The physician has, by his conduct, demeanor, words, and action, made a strong impression upon both patient and family, and the fear that he has thus implanted into the minds of all in the household has kept up a depressing environmental influence which has got in its effective work upon the patient.

The lady in question is suffering with acute pneumonia. She feels a decided pain upon breathing, experiences a sense of suffocation, and the paroxysms of coughing have rendered her decidedly conscious of her illness; and now the physician in whom she has placed her trust has looked serious and given directions in a way that speaks louder than words in unduly exciting her. **Not one word has he said** to allay her anxiety, soothe her mind, assuage her fears, or inspire hope.

Upon his second examination he finds his patient decidedly worse, as might have been expected, and now he is serious, sure enough. His fatalities in the treatment of pneumonia have been particularly large, and he much dreads this disease; and seeing his patient with a higher fever, a more rapid pulse, flushed face, more anxious expression, and remembering his past record with such cases, he makes no effort to conceal his gloomy forebodings.

Again giving directions for the night, he starts for his conveyance, and when out in the hall the members of the anxious family, who have followed him, turn with pleading faces and inquire, "Doctor, how is mother?"

"Very sick, very sick," is his reply. "Watch her carefully tonight. Keep the house as quiet as possible, and if she should get worse before morning, be sure to call me."

Before the next day he has been called, for his patient has been unable to sleep, and from his point of view a hypodermic of morphine is decidedly indicated.

On and on this management goes, and if finally his patient recovers after two weeks of severe illness, which she might possibly have done in spite of her physician, that family are grateful to God and the doctor for having "pulled her through."

I remember once going to see a lady about fifty-five years old, **with acute pneumonia,** a decided congestion of the lower lobe of the right lung, and after carefully making out my diagnosis and prescribing for her medicinally, I turned to the patient and gave her a talk about as follows: "You have pneumonia, Mrs. Blank, but only a mild case, temperature only 103.5°F., but a good pulse and everything is favorable to a nice recovery. **You are in pain,** but a hot poultice I have ordered will relieve that very promptly. You will soon get comfortable and will rest well tonight and be feeling much better tomorrow when I see you again. Now, be patient, and in from seven to ten days you will be well. **The medicine prescribed for you** will keep you comfortable, strengthen your heart, keep your nerves quiet, steady and strong, and all will be well with you."

With tears of gratitude in her eyes, she answered, "Oh, doctor, you make me feel like I am well already. I feared that I had pneumonia and felt that I never would get well."

"You are going to get well all right," said I, "going along nicely to recovery. Your daughter will have entire charge of your medicines, and knows just what I want you to have in the way of nourishment. **After the hot poultice** is applied, you close

your eyes and go to sleep, you will rest nicely and feel much better when I see you tomorrow."

Upon my return the next day she smiled pleasantly as I entered and bade her good-morning, and when I felt her pulse and remarked, "You are better," she answered, "I feel much better, doctor."

"Going right along to recovery, madam. Now, I shall see you day after tomorrow."

"See her every day if you think best, doctor," exclaimed her son. "We want mother to be well real soon."

"I can't trust everybody as I can you, so I will not come tomorrow unless you call me. She is going to do well. Keep out all visitors, continue all directions, and I will see her again day after tomorrow."

I saw that patient only twice more, and at the last visit assured her that it was a pleasure to come into her pleasant family, but that I was going to turn her over to the entire charge of Mrs. Blank, her daughter.

"If you feel it necessary to consult me again, just whistle and I will come."

In about seven more days the son came to know if his mother had better have a tonic; he said she had had no fever for three or four days and was entirely well. Her lung cleared up upon the ninth day of her disease.

I do not mean to say that all pneumonia cases should be seen only four times. In fact, a daily visit or two is indicated in most cases, but the case in question serves to illustrate the

part that the psychological factor plays in an ordinary case of illness.

Many people die who would get well if given a chance to allow their protoplasmic energies to assert themselves.

Out in California I was invited by a physician to go with him on his rounds through the County Hospital. **Six pneumonia patients** were in one of the wards, four of them old men. The majority of these were chronic alcoholics and only one was delirious or appeared seriously ill.

"But one death from pneumonia in five years, in this hospital," was the physician's record up to that time.

"How do you treat them?" I inquired.

"Keep them comfortable, give them hospital tea (sweet milk) and let them have old Frank to keep them feeling good." **"Old Frank,"** as the hospital physician styled the genial German superintendent, carried sunshine and good cheer into those wards at least twice a day. **He had then been in his place** for seventeen years, and the therapeutic value of his personality to that institution would be hard to estimate. He knows how to get the confidence of men and women and how to keep them feeling good when they are sick. **Many a poor tramp,** who has only seen the rough side of life, has felt soothed by his kindness, and buoyed up to recovery by his optimism, while being controlled by his firmness.

There is no disease in which the influence brought to bear upon the mind of the patient so determines the recovery or non-recovery as pneumonia. **It is a self-limited disease** and those influences which soothe the mind and quiet the nervous system

bring about a complete re-establishment of the nervous equilibrium, allowing the blood to circulate normally through the peripheral blood vessels of the body, and thus relieve the tension or high pressure upon the heart and inflamed lung, with its fatal termination to pneumonia patients.

One of Old Frank's characteristics is kindness, which is encouraging in contradistinction to sympathy, which is depressing and weakening.

There is more or less mental depression in all pneumonia patients, as the individual is rendered painfully conscious of his helplessness. This results in fear, and such sufferers enjoy sympathy as they enjoy morphine, which inhibits the normal physiological processes and stealthily lessens their resistive powers to the disease. **No worse influence** can be exerted over the patient than the presence of a highly emotional person, who lavishly pours out sympathy to the destruction of all the optimistic and strengthening qualities of mind and body. **So great are the influences** brought to bear by the mind over the physiological processes of the body that a physician who unconsciously uses the power of suggestion to the detriment of his patient, actually makes a very serious condition out of a trivial disorder.

On the other hand, by the intelligent and judicious use of suggestion, we can make a very trivial disorder out of a seemingly serious pathological condition, so far as the results are concerned.

The injury done to the unsuspecting public by physicians who are ignorant of the use and power of suggestion, is far greater than is commonly supposed. **Whole communities** have

become fear-stricken by the exaggerated serious reports of this class of physicians, who frequently ride day and night to see the victims of their perverted influence. **Their very influence** in the community in which they live spreads like a contagious disease, emanating from a focus, which stealthily moves among, them, reaping financial reward for their indiscretions.

"Very sick, very sick," is their watchword, as they implant fear in their trail.

While the laity are properly being educated in the necessity of self-protection from the contagiousness of tuberculous disease, malarial and yellow fever carriers, and other infections, for the safety of their own lives, they should also be protected from that **pest to any community,** the physician who unduly exaggerates the condition of his patients by reporting all cases as being seriously ill.

CHAPTER XX.

ENVIRONMENT—ITS INFLUENCE IN THERAPEUTICS.

Only the practical aspects of this subject remain to be considered.

A physician in general practice must not only treat his patient, but be in absolute control of the environmental influence brought to bear upon him as well, in order to secure the best results.

The sick room, especially in the small towns, and rural districts, is often the meeting place for gossipers, who unconsciously exercise a great influence upon the patient, frequently preventing recovery in an otherwise curable disease.

To say nothing of the value of quiet, rest and sleep, which is hindered by this procedure, the discussion of other cases of a similar kind that have terminated unfavorably and which had come within the experience of the visitor, or remarks relating to the procedures of another physician whose methods are different from your own, all exercise an unconscious influence that makes the patient nervous, excites fear, and proves destructive to that confidential relation which should exist between patient and physician.

The physician who is timid and allows this state of affairs to exist, to the detriment of his patient, is jeopardizing his professional reputation.

A loud-mouthed, self-assertive woman, who is the unconscious drummer for a competitor, is to be found in every locality.

Seeing the harmful influence of such an individual upon a patient with a continued illness, the simple instruction to "admit no visitors" is usually sufficient; but the madame in question is not always repulsed so easily, as she unduly exaggerates the importance of her presence to the welfare of the sufferer, and enforces her entrance in spite of your injunction, which she considers does not apply to her.

My own custom has been, under such conditions, to give my patient or his family the choice between my services and those of this unfriendly visitor.

Useless antagonism, however, never pays upon any occasion, but where the welfare of your patient is at stake, people will appreciate any stand that you take in his behalf. **"Do what's right,** come what may," is a safe rule under any and all circumstances, and the self-respecting physician should exercise the courage and self-assertiveness to face these problems and leave no stone unturned that might retard the recovery of his patients. **The successful men** in the medical profession are those who have the stamina to stand by their convictions and allow no intervening meddler to poison the environment of the sick room.

In a large class of cases it is absolutely impossible to obtain successful results in private practice, on account of our inability to secure the right environment, and here is where sanatorium and hospital facilities give the physician a wonderful advantage. In such places the environment is absolutely under his control and direction.

We should overrule any factor in private practice, however as far as possible that will in any way set up an undesirable mental attitude on the part of the patient as regards his own condition, or that will create mental states that are injurious; for mental states influence metabolism, and encourage or retard all the normal physiological processes, and wonderfully help or woefully hinder the recovery of your patient.

In all classes of professional work, there is a fine art in adapting one's self to whatever environment one may be thrown into, and in maintaining that prestige which the successful physician must never surrender. **When to be dictatorial,** when to to coerce, when to be lenient and kind, and when even to soothe and palliate by your presence, and at the same time be in absolute control of the situation, are all important considerations in the successful practice of medicine.

People sometimes need to be aroused and lifted out of mental states which prove to be adverse to their recovery, and new ones substituted in their place; and this applies not only to the patient, but to everyone coming into his or her presence. **It is our duty as physicians,** to create an environment wherever our patients are to be found that will help to make them get well.

To illustrate, here is a patient sick with pneumonia, a disease that frightens the majority of people. On my second visit I find the family and others in attendance depressed and downhearted, which, of course, renders the patient morbidly conscious of his condition. **It is evident to me** that I must alter that environment and re-establish hope in my patient or the outlook is very grave. Do I send for a consultant? Not unless it

is a baby less than two years old. **What I do is to look** every member of that family squarely in the face, and kindly but positively tell them, and also the patient, that he is going to get well. **I have frequently emphasized** that suggestion, and assured the patient that I had seen a hundred people ten times sicker than he with pneumonia, and the last one of them recovered.

Then getting close to him with my hand on his head, I quietly and calmly assure him that I have never treated a pneumonia patient above two years old who did not get well, with the single exception of one old man who had a bilateral pleuro-pneumonia, with an enormous effusion, **and I tell the truth.**

I leave that home with a newly created helpful environment as a therapeutic resource, and under such conditions my patient is enabled to relax and to proceed with a consciousness that gives rise to mental states favorable to his recovery.

Do I depend alone upon the psychologic factors thus set in operation? No, I give my patient the benefit of every other possible therapeutic adjunct, from the application of a brick, heated to a red heat and placed in boiling water and allowed to remain therein until all simmering ceases, wrapped in a woolen cloth, and the moist heat confined by a blanket to the diseased lung, or a corn-meal and mustard poultice, renewed and applied hot every hour or two, or an ice-bag in their stead, to the use of all other measures, medicinal, dietetic, and hygienic.

The hot brick, taken out of boiling water, has a weighty physiological significance, aside from being an excellent vehicle

to retain heat and moisture, which it gradually liberates to the great comfort of the sufferer. **I do not hesitate** to tell both my patient and his family that this hot brick relieves the pain, relaxes the patient all over, and causes the blood to circulate more freely to the periphery, and thus relieves the lung of its congestion and inflammation, reduces his temperature, enables him to sleep and helps to make him a well man. **I tell him in perfect candor** and truthfulness, that I have never known a patient who has used the hot brick heated to a white heat and then taken out of boiling water and applied as indicated, to fail to recover.

Is the point clear? I am using that hot brick as a means of suggestion. Aside from the therapeutic value of heat and moisture, this harmless palliative resource is used to substitute sense impressions that are pleasant and comfortable in the place of existing ones that are distressing. **This enables my oral suggestion,** strongly and emphatically driven in upon his consciousness, to call myriads of living cells in his organism into helpful, useful and active service.

In a crisis like this the entire picture of the disease is changed by the personality of the physician.

CHAPTER XXI.

THE BRUTALITY OF FRANKNESS.

HONESTY IMPERATIVE.

A physician who fully appreciates the influence exerted by suggestion upon the mind and the influence exerted by the mind over the physiological processes of the body, will habitually give a more favorable prognosis than the one who does not appreciate the potency of such measures.

Every physician who has successfully practiced medicine for a few years has observed instances where the family of a sick member, upon becoming aware of the attending physician's grave prognosis, has insisted upon having a consultant, who, upon his advent in the sick room, has taken a more hopeful view of the patient's chances for recovery, and at once a marked improvement has begun, which has not abated until complete restoration to health has been secured.

A medical man in the West related this experience: He was once called to see an Indian chief, seriously ill with an acute double, lobar pneumonia, with high fever and severe pain. **After a careful examination,** he frankly and honestly made it known to the family of the sick warrior that in his opinion he could not get well and would have to die. **The brave old chief** did not so easily take his suggestion to die, and he refused to accept the physician's services, continuing to take a well-known Indian remedy, to render him less conscious of his suffering, and while surrounded by weird noises and dances and other savage

ceremonies, the recuperative powers of the cells of his organism were allowed to assert themselves, and he made a safe recovery.

To this day that tribe of Indians refuse to accept the services of physicians, having had the strong conviction implanted that the white man's medicine is unreliable.

A gentleman of my acquaintance was sick for many months with chronic interstital nephritis, probably of alcoholic origin, and a competent pathologist found large quantities of tube casts in his urine, which bore a large percentage of albumin, and with his report gave his opinion that the prognosis was grave. **His attending physician** and also a consultant, gave him no encouragement. He was persuaded to take an infusion of some kind prepared by an illiterate farmer who was strongly convinced that this would effect a cure.

His physicians allowed the harmless experiment, to satisfy his patient, who was eager to try anything that offered a possibility of recovery. **With every dose** of the infusion, however, he became more influenced by the farmer's conviction of his recovery, and he began to improve from the time he commenced the remedy, till within a year was able to attend to business.

All cases of degenerative kidney disease are not necessarily fatal, but he was steadily growing weaker all the while until he began the farmer's prescription, which probably benefited him more through its psychic influence than otherwise.

I was called some years ago in consultation to see a little boy ten years of age, possibly infected with malaria at first, but he also had a sub-acute gastro-entero-colitis. He had been

sick for nearly two weeks and was still having frequent, watery, mucous discharges from his bowels, and had, for thirty-six hours, vomited everything taken into his stomach. He had a pulse of 150, temperature 100.5°F., pale, weak and anaemic. **His physician** had given him the standard medicinal remedies, as recommended by our best authorities upon children's diseases, and the child was constantly growing weaker. **He had notified the family** that the outlook was grave, and was quite willing to adopt any suggestions that I might offer.

I endorsed all his measures, but suggested that they be discontinued, on the grounds that the results did not warrant their further use. **He was anxious** for me to share the responsibility of the situation and readily consented that 1-30 grain calomel only be given every hour while the patient was awake.

Sitting by the bedside, I dipped my fingers in a bowl of ice water and began gently to stroke the little sufferer's forehead. I was alone with him at the time while the attending physician was out of the room with his mother, giving orders for the day. **By the time they returned** to the sick room I had suggested the patient into a refreshing sleep, and had also given him other suggestions, appropriate to his condition. **That he should be asleep** was somewhat of a surprise to his mother, whose anxiety and nervousness had served to keep him from doing as well as he would possibly have done had she been more self-composed.

"Will you do me the favor, Mrs. Blank, to take that bowl away from the bedside, and remove all towels from the bed also?" I asked.

"Why, doctor, the child would vomit all over his bed and also on my floor," responded she.

"**Madam, take the bowl away** and cover your floor and his bed with newspapers, and if he vomits one time, put them back. He will rest well to-day and sleep most of the time. You will have to awaken him to give the tablets, but that will quiet his stomach and keep him from vomiting again. **Keep the room absolutely quiet,** allowing no conversation at all to disturb him. Allow him to drink all the water he wishes when you give the tablet, to quiet his stomach and make him sleep. **He will want some chicken and barley broth** to-morrow, and if Doctor Blank says so, I think he will enjoy it."

The mother looked queer, but removed the bowl and towels. I also requested her to tell him to go to sleep when she gave the tablets.

The little patient rested well that night, and when we returned again the next day, his face brightened and he smiled as he bade us good-morning.

"**Oh, he is so much better,**" exclaimed his mother, "and he is begging for something to eat." He improved every day and went on to recovery in due time.

Every word spoken by me to that mother while the child was asleep was a suggestion, an indirect suggestion, which is always the most powerful kind.

Even a child four years old appreciates sense impressions, or suggestions made upon his brain cortex, far more than is realized by people and physicians in general. **A little boy** of my knowledge, four years of age, was sick with an acute capillary

bronchitis, and his father, who was a physician, felt much concerned about him.

His mother, as was her custom, at bedtime began to have him recite his infant's prayer, and after her the child repeated: "Now I lay me down to sleep, I pray the Lord my soul to keep, if I should—"—there he began to have a paroxysm of coughing, and when he could speak again, he said, **"Mamma, mamma, I don't want to say any dying prayer,** I want to say a living prayer, like that papa told you."

The substitute for the standard orthodox style of prayer had been learned from one of the current journals and went as follows:

"Now I lay me down to sleep,
I know the Lord my soul shall keep,
And I shall wake to see the light,
For God **is with me** all the night."

To satisfy the child and his mother, the father said, "Yes, my boy, we don't want a dying prayer, when we are sick at least," and he repeated the substitute, the child saying it after him, and then went quietly to sleep.

If an ignorant Indian chief, that child of the plains, and **a little four year old boy,** can appreciate a living prognosis and a living prayer, so are all men and women influenced by sense impressions or suggestions that a gloomy prognosis produces, with its weakening, paralyzing, inhibitory influence to all the nerve centers.

It is a physician's duty first, last, and all the time, to do that which will help the patient to get well.

There are many instances where, in a case of extreme illness, **the only help** that can be given a patient is to inspire him with hope, encouragement and optimism, allaying his fears, and bringing about those conditions necessary for the physiological processes **to accomplish the work of restoring** the patient to health.

By the influence exerted upon the mind, we encourage all the physiological processes, and thus, through them, convert potential energy into dynamic energy. We help the cells of the body to accomplish their work of fighting the etiological factors of disease, whether due to pathogenic germs or to other factors.

Physicians have frequently reminded me, in discussing this phase of our subject, that they have repeatedly witnessed a rapid lessening of the resistive powers and speedy death, as soon as they rendered an unfavorable prognosis, given frankly and honestly in response to the question, " Doctor, do you think I am going to get well ? "

If a patient who is extremely ill has important business matters in mind that are worrying him, let them be arranged to his satisfaction, upon the ground that it will help him to get well.

To such questions as " Am I going to die ? " you can evade a direct answer by giving one that will be perfectly satisfactory to your patient, and at the same time will create sense impressions that will set up a different line of thought.

I prefer so to impress my patient that such an idea will never come into his mind, and, also to engage the services of every

member of his family to help me to accomplish this result, while on the outside I take them into my confidence and express my opinion to them honestly and frankly.

Even in a case of acute multiple neuritis with high fever, intense pain, hyperaesthesia and great tenderness, in which the disease reached its height in ten or twelve days, I was enabled to maintain a mental stoicism that was remarkable, and at the time of the patient's most distressing symptoms, he repeated back to me the suggestion that I had so often iterated to him. **I had so often** said to him, " You will get better," that he began to ask for the suggestion by saying, " I will get better, won't I, doctor? " **It was some months** before he was able to go about on crutches, but I never let him get away from the conviction of recovery.

At the time of the Galveston flood an unfortunate man was picked up perfectly helpless, in a half drowned, wounded condition, and for six months lay in bed wearing a plaster cast for a severe injury to his spine. **Two years later** he was hobbling on crutches, which he had been using for many months, but he was unable to get his hands to the floor and rise again without support. **He was in constant pain,** had numerous functional disturbances, insomnia, indigestion, frequent movements from his bowels, headaches, etc.

When I saw him I felt that possibly his nervous system was retaining impressions after the results of the physical injury which caused his pain, disturbances of locomotion, and other symptoms, had been removed; and, at the request of his physi-

cian, I gave him three suggestive treatments, using hypnotism as a means to secure the most effective results.

All his symptoms were relieved, including his indigestion and bowel complications, after three or four treatments; he put aside his crutches, and a week after the last treatment was comfortable and happy.

In all classes of practice the therapeutic value of suggestions, strongly put into the brain plasm of your patient, will help him to get well where recovery is impossible.

In some classes of work all that a physician can accomplish for the patient is to help him to endure his physical disabilities. **This includes such cases** as where the organic structure of the nerve cells is involved, atrophic changes have taken place in the spinal cord or any other parts of the motor nervous system, as well as inoperable pathological conditions, resulting from malignant disease, tuberculosis, and all such cases as are beyond the pale of recovery.

Even in these cases, however, we can use suggestive measures to enable the patient better to endure his sufferings, and do so, without the aid of hypnotism, much to the comfort of both the patient and his family.

In two cases of malignant disease—in one case, of the uterus, —in another, of the stomach—occuring in two people above the age of sixty, I kept them each so cheered by constantly holding before their attention a contemplation of their past lives which had been filled with usefulness, of duty done and successful achievement in their own humble way, and so pointed out the moral heroism that they were displaying and the value of such

an example of cheerfulness and optimism, that they were enabled to meet **that sweetest and most welcome of all relievers of pain** and suffering under such existing conditions, death, with hardly a word of complaint.

If our patients have sufficient recuperative powers to give even the slightest hope of recovery, let us strengthen that hope and help them to get well.

If they are ill with incurable diseases, we should help them to endure their suffering, all the while working for their recovery even without the slightest ray of hope to encourage us. **Thousands and thousands** of such efforts have been rewarded by the recovery of apparently incurable patients.

A million years of advancement and progress will not have rendered our most expert diagnosticians sufficiently competent to prognosticate with infallibility, in all cases, against the determined and persistent effort of the truly alive physician who will stand up with all odds against him and fight for the recovery of his patient with every available therapeutic resource.

Absolute honesty and sincerity, under all circumstances are imperative to the self-respecting physician, but the weakening, paralyzing, discouraging frankness of the pessimist is brutal.

CHAPTER XXII.

PHYSICAL AND MENTAL HYGIENE.

The care and training of the body is the first step toward self-development. Other things being equal our most successful men in all professions are those of strong, vigorous physiques.

The sooner that every individual comes to realize that his physical anatomy is the most valuable piece of property that he will ever own, and that its proper care and preservation will, in a very large measure, determine his success and happiness in life, the better will he be prepared to guard against those abuses that dwarf its growth and development.

Children should be taught that the power and privilege is theirs to maintain and preserve the body as an instrument of health, strength and beauty. It is so often the case that the physical man or woman of the future is dwarfed and ruined by its misuse in childhood.

Morality itself is the result of environment and education, and many children and young people make blunders that maim them for life, weakening body and mind on account of the failure of the parents to instruct their children earnestly and seriously concerning the laws of procreation and reproduction. **In their ignorance** they are the easy victims of self-pollution and vice that leads to the consequences that fill hospitals, insane asylums and penitentiaries. Here also is the source of frequent suicide, divorce, murder, disease and death.

To send children to church and leave all moral guidance to its influence is not sufficient. **It may appear beautiful** to teach a boy to sing "There is sunshine in my soul today," but we who have seen the miserable mental depression and physical suffering resulting from gonorrhea and syphilis contracted by unthinking youths, know that it is far wiser to talk to them plainly about the sexual functions and to give them that knowledge that every boy is so eager to receive, and thus save him from the pitfalls that lurk in his path by an earnest appeal to his reasoning faculties.

Many people look with disapproval upon any effort to solve the question of social vice. They pride themselves in their ignorance and call this purity. **Violations of natural laws** in innocence and ignorance, however, are attended with the same penalty as other crimes of misconduct.

If suggestion is of value anywhere it is in such cases as these, upon the principle that an ounce of prevention is worth a pound of cure. **To teach children to pray** "Give us this day our daily bread" and not show them how to work for it is criminal neglect. **To have them sing** "We will walk in the light" and not forewarn them of the consequences of physical degradation and vice is mockery and deceit.

In early childhood is the time that we can plant sense impressions or suggestions upon the soft tablets of their brain plasm and so form habits of thought and action that will make them conquerors in life. **The evil consequences** of vice to the development of both mind and body should be explained to children

and constantly iterated and repeated by those responsible for their care and training.

They should be made to feel that every part of their body was created for a purpose and that function should be carefully explained to them. **They should not be allowed** to become ashamed of their procreative organs, but should be taught to regard their care and preservation as a sacred trust, and that upon that care and preservation their future happiness will largely depend.

They should be taught the necessity of thorough cleanliness to prevent the consequences of irritating secretions that so frequently lead to masturbation.

To let a girl know that the passions that she experiences are the same that prompted the marriage of her own sweet mother and the act which culminated in her own birth, is to plant knowledge that is power that will be manifested in the production of character and pure womanhood.

Tell her that the passions that she experiences are given by the same animating power that causes the flowers to bloom in spring and the birds to sing in summer and let her know that these signs of awakening sexual life are Nature's call to her to be prepared for the responsibilities of motherhood.

Let her know that such passions are but an evidence of energy that seeks to find expression in her life and conduct, and that such energies can, by reason and will, be turned into intellectual and physical development.

The sexual impulse is in essence the same impulse that finds expression in music, poetry, literature and art.

It is the primal impulse that gives rise to the preservation of the species and creates the home, in which the little ones of earth are nurtured and protected.

It is the impulse that gives rise to educational institutions and to forms of government.

It finds expression in mechanical arts, invention and navigation.

It has manifested itself in the discovery of new countries, the clearing of the forests, the building of cities and the construction of railroads.

It is the impulse that gives rise to all the achievements of science and the birth of all philosophies and religions.

It is the instinctive impulse that has prompted human activity in all ages, which was formerly ascribed to an anthropo-morphic deity.

This awakening sexual life in boys and girls is an evidence of physical energy that can, by wise and judicious suggestion, be directed into deeds of usefulness as varied as the vocations of man.

It can be turned into channels of intellectual and physical development. **In wholesome employment,** in work of all kinds, in outdoor sports and exercises and **in mental and physical action;** in a thousand ways can this sexual energy, under the guidance of reason, find expression.

It is about the time of puberty that every healthy normal boy or girl feels an impulse to do something. This impulse can be expended in self-abuse or sexual intercourse or emotional re-

ligious worship to the great harm of both mind and body—in prostitution pure and simple.

But show a boy or girl how to convert or direct his or her energies that are seeking to manifest themselves, in useful and healthful lines of employment for the development of both mind and body, and the result is healthy, happy, self-reliant, virile men and capable women.

All strong characters of all ages are and have been strongly sexed. **A vigorous sexual nature** is the logical accompaniment of a great intellect and a strong healthy body.

What boys and girls, men and women, need is to know how to convert and direct their energies into useful channels of thought and conduct, and not to prostitute them in worry, emotion, passion, self-abuse, sexually as well as from whisky and tobacco, and in a hundred ways that lead to weakness, illiteracy, degeneracy, disease, poverty, crime, divorce, suicide and death.

Properly conserved and directed, however, the same sexual instinct produces men and women strong, capable and free in body and mind.

Many of our patients need to be taught how to direct their lives into natural and healthful channels of thought and action, as well as to have remedial measures that will help to correct the physical disability which has already been incurred on account of their own indiscretion.

Here is a young man who did not have the proper instructions upon the lines indicated. For several years he was a victim of self-pollution, and finally when he attempted to stop his disgusting habit, he was annoyed by nocturnal emissions. **It is**

the same old story. Quack literature fell into his hands, which unduly exaggerated his symptoms and suggested "loss of manhood," and planted fear into his mind. **He is unable to sleep,** all bodily functions are disturbed, his physical condition is below par, he is unable to concentrate his mind upon his studies or his business. **He feels a great sense of unworthiness** in the presence of the pure young woman that he would wed, but for his miserable psycho-neurotic condition, and this unduly aggravates his despondency and morbidness.

If he falls into the hands of an advertising quack who guarantees a cure, he is bled to the utmost of his financial ability. **But he comes to you.** Tactfully you draw him out upon every phase of his case. You assure him that every uninstructed boy was once the innocent victim of such habits and allay his fears of going insane. **You explain to him** that such practices are of themselves harmless, aside from the useless waste of energy that should have been directed into normal channels of physical and mental development and the loss of self-respect which it has caused him. **You advise a liberal, wholesome vegetable diet,** with meat but once a day, and plenty of water to encourage elimination, systematic physical exercise, deep breathing, etc., but above all, **by suggestion you drive back the morbid sense impressions** and substitute new ones in their stead by your own persuasiveness and encouraging optimism. **You appeal to the highest and best** that is in him, and show absolute confidence in the outcome, but insist upon a rigid conformity to your instructions.

You further advise him against testing his potency with a prostitute, and if he has taken such steps to prove the correctness of his own opinions as regards his impotency, you assure him that his failure to cohabit with such a creature only proves the highest type of manhood. **You see him often enough** to build up his physical and mental constitution and to establish wholesome habits of thought and action.

Such cases are attended with excellent results where the quality of brain plasm is such as to get a reaction from the sense impressions or suggestions made upon it.

Children should be so trained that their habits of thought and action during the first twenty-five years will produce strong bodies, clear minds and buoyant, happy spirits. **The best development** comes in the unconscious exercise of a child's faculties in wholesome endeavor and useful employment, such as will call both mind and body into action.

CHAPTER XXIII.

SUGGESTION IN EDUCATION.

The prime purpose of education is to equip the individual to make the struggle for existence.

More than ever before do we now realize that this necessitates the development of the body as well as the mind; that body, mind, and character, are all qualities of the one individual and that it is practically impossible to elevate one quality while the others are weak or degraded.

The problems of health concern all that contributes to the evolution of the individual, physically, mentally and morally.

The capacities and capabilities of the body should occupy more consideration in our educational system than is done at the present time. **When education or religion** interferes with the physical development of children, it strikes a weakening blow at the quality of brain plasm possessed by the child, and to obtain the best results in mental development, this should be kept at a high standard. **Moreover, any factor** that retards physical growth and development, while education is enforced, seriously jeopardizes the life of the individual, and our American cities have thousands of physically weak, neurasthenic boys and girls who have been maimed for life under the strain of the existing educational methods.

Everyone should be environed by those conditions that maintain the highest standard of protoplasmic energy during the period of childhood and adolescence. **The impressions that are**

made upon the brain through the senses from the cradle to the grave are the suggestions that constitute the education of an individual. Here those that are useful and good, or harmful and false, are alike recorded, to furnish foodstuff for the mind, which is manifested in thought and conduct.

School training, after all, consists only in furnishing an environment in which certain suggestions, ideas, mental pictures, concepts, or impressions, can be photographed on the rapidly developing cerebral cells. Here consciousness itself is evolved, habits are formed and a new world is opened to view as the child's perceptive powers are strengthened and individuality begins to assert itself.

While a certain quality of physical traits and habit tendencies is transmitted to the offspring, by far the most potent factors in making children what they are are the inherited environmental conditions which bring to bear upon the child their unconscious suggestive influences. What we are is largely the result of what we have experienced in life. Habits of thought, traits of character, religious beliefs, moral convictions, etc., are all directly the result of impressions that have been registered upon our cerebral cells. Environment contributes both to our physical and mental constitutions.

In the slums of one of our great American cities I noticed a little two-year-old child, without shoes and bare-headed and dirty, in ragged clothes that scarcely covered its poorly nourished body; reared in filth and poverty, with a drunken father to abuse its weak-faced mother who tolerated her pitiable state of existence because she did not know any better. Had she been

taught to work, and to think and do for herself, she could easily have extricated herself from this miserable role.

That a child born under such conditions should become a prostitute, contract disease, and die before she was scarcely out of her teens would be as natural as the law of gravitation.

A girl whose father at the time of her birth was occupying the position of president of a great college and who was reared in the lap of education and refinement, could have been nothing else than the mathematical resultant of the parallelogram of the forces that environed her.

A little child of my knowledge was taken at six months old by a couple of kind-hearted people who provided it with all the physical necessities of life. They saw in this little one latent possibilities and potentialities that could be developed and trained into active, useful service, and they enjoyed watching its growth. **They said she was beautiful** and the child smiled and cooed and grew more beautiful. They informed their friends that she was smart and every day reminded the little one of this belief in her, and, at an early age, she did all sorts of useful service. **They said that she was good and obedient,** and true to the law of suggestion, they moulded those very qualities in her. They loved to listen to **her merry prattle** and she early acquired a vocabulary of words to express her ideas.

Later, when she started to school, they believed that she would excel in her classes, and she led in every study. They encouraged her efforts to imitate her foster mother **in cooking,** and, though she soiled her clothing and wasted material, they were pleased, and she soon became an expert cook. **They appreci-**

ated her efforts at the piano, and she developed into a talented musician.

Still later in life she married, and was the pride and helper of her husband, and an honored woman in her community.

Such was the culminating force of suggestion in the home life in its influence upon the life and character of a motherless waif. Who can dispute the saying that " men and women make men and women " ?

" You are a bad boy, just as bad as you can be, and I will never let you come down town with me again," said a mother to her little six-year-old, who was the impersonation of the character that his mother had exhibited for him every day of his life.

Children are usually just what their parents make them.

A little four-year-old boy was playing on the floor with his fifteen-months-old baby sister, and he impulsively jerked some of his toys from her baby hands, and she in turn began to cry. The mother, who was quietly sewing nearby, witnessed the incident and looked up serenely, and in a subdued tone, called young America to her. He sulked up to her with a face that indicated that his rights were being transgressed, and he was not disposed to stand for it.

" Kiss me, my boy," said she, while she implanted a kiss upon his forehead. She then good naturedly placed her fingers under his chin, and with his face upturned to hers, quietly said to him, " You are mamma's little man, you are a good boy. Yes, you are; you are a good boy, and I know you are going to be just as sweet to your little sister as you can be. She is a little

baby, but you **are a little man.** Now, I am going to see if you aren't."

In a few moments the mother looked up again and her little son had piled all the toys he could find around his sister, and now sat upon the floor, looking first at her and then at his mother, trying in vain to suppress his delight in his mother's approval which he seemed sure he would get. **"I told you so; come and kiss me again,"** said she, making a quick move as if to catch him while he dodged from the room with a joyous ha! ha!

The greatest factor in the education of a child, and the most important element in the development of character in children is the confidence that we show them; for the confidence reposed by others in us determines the estimate that we place upon ourselves. **To believe in a child** is to beget self-confidence in that child.

After we are older, and have more experience in the world, we are able to excuse ignorance and we only crave the confidence of the best people; **by this** we estimate ourselves, but in children the love and confidence and expressed appreciation of those nearest and most closely related, is the most powerful factor in the development and growth of all the latent elements of manhood and womanhood.

Children easily enter into sympathy with those with whom they are constantly associated, and the blighting influence of a home in which violent displays of temper are made or hysterical conduct in any form is exhibited, is harmful to both the mental and physical development of children. Here they

unconsciously acquire habits that frequently last them through life.

In the use of suggestion upon children for the correction of vice and the cure of evil habits, moral perversions, etc., both with and without hypnotism, no rule can be given that will apply to all children alike. **One must know children** and deal with each one according to his or her own individuality, first securing their confidence. They are very suggestible without hypnotism, and easily come under any influence by those who have their confidence.

In one of our large cities a revival meeting was conducted by an advertising revivalist, under the auspices of several of the leading orthodox churches, and his text for seven days was "Hell, the kind of place it is and who is going there."

The physicians of that city were more than ordinarily busy during this period, on account of the psycho-neurotic condition induced by the fear that such preaching had implanted in the minds of unthinking men and women.

At one of their special services for children, held by the revivalist during the latter part of his stay in that city, only "workers" were invited, besides the children, thus securing such an environment and suggestive influence that hundreds of children, who were incapable of thinking and reasoning for themselves, were coerced into joining the church. **Under these circumstances children are unconsciously** moulded into a particular line of religious belief which but reflects the opinions of their parents or the makers of their church creed, and under this influence they are reared and educated. **The power of**

choice is denied them, and they grow into manhood and womanhood stamped as if they were so many bricks.

We might as well expect to make a race horse out of a colt that had been imprisoned in a stable all his life, as to expect children reared under such an environment to become broad-minded, truth-loving men and women. As self conscious, independent entities, they are not allowed to think for themselves, and failing to exercise their intellectual faculties their minds become dwarfed and useless. How many people are born and reared under such an enforced environment from which they are never able to extricate themselves! They acquire a one-sided way of seeing things, and such mental processes continuously indulged in, form habits, and such mental habits form fixed anatomical grooves or channels in the brain plasm to the extent that it becomes impossible for the individual to think or believe any other way.

Mental faculties are mainly acquired and are the product of environment and education. Chief among these are memory, imagination, speech, knowledge, conception, judgment, will and reason.

Reason is mankind's highest, truest, noblest faculty, but it is only able to draw conclusions from the light of experience.

Many advanced thinkers believe that "the will is higher than the mind, and that its rightful prerogative is to govern and direct the mind just as it is the prerogative for the mind to govern and direct the body." This seems to be true when we see an individual using his entire mental equipment at a given salary to promulgate a fixed religious dogma, or when "a

lawyer receives a retainer and commands his mind forthwith to busy itself with all its resources of reasoning and persuasion for the party who pays him. **Even his emotions from the extremes of pathos** to those of indignation may be pressed into the service as well."*

There are others who deny that there is such a faculty as " will " who take the position that mankind **is impelled to action by desire and held in restraint by fear,** and between desire and fear each human being stands.

Yet even will, desire and fear are only qualities of the individual body and mind and they conform to the general law of evolution, being the outcome of heredity, environment and education.

The logical conclusion, then, is that each human being is what he is, by the operation of the same infallible law that moves the earth around the sun, and that holds the stars in their places.

People mean to do well. They are seeking happiness **as best they know how,** according to their instinctive impulses inherent within the protoplasmic mechanism of the physical organism, modified or guided by knowledge and experience.

Some of the greatest, noblest, truest characters that exist in the world to-day are clergymen, who are so far in advance of the creed of the church under whose jurisdiction they are laboring, that they have become a law unto themselves. **They have been impelled by desire** to do that which is right, and

* Thompson: "Brain and Personality."

useful, and true, until they are found standing in orthodox pulpits, fearlessly doing all within their power to liberate men and women from the tyranny of creeds and dogmas, ignorance and superstition, through which all creeds have been evolved. **They are interpreting the problems of life** in the light of present-day knowledge and eagerly seeking the contributions shed upon the pathway of human endeavor and achievement by the light of science.

"**To live by science** requires intelligence and faith, **but not to live by it** is folly."

Men stand where they are in the world to-day held by the tyranny of fear and ignorance, unless liberated by knowledge and experience. **Frequently physicians,** who stand high in the medical profession, have said to me frankly and honestly that they felt the necessity of a more thorough knowledge of the theories and methods of using psycho-therapeutics, but they "were afraid their practices would be ruined if the people should find it out." **When such men are teachers** in our medical colleges, their pupils bear the stamp of moral weakness upon their professional characters. **They are the legitimate product** of weakness and fear as manifested in the personality of a physician.

On the other hand, the output of the majority of our medical schools **does not stand in the slavery of fear** because their faculties are constituted of men who were open minded and fearless.

A most valuable part of education is the incentives and intellectual ideals implanted through personal association.

CHAPTER XXIV.

MORAL STAMINA—A THERAPEUTIC POWER.

As we learn to discriminate between people of other classes presumably of like character and qualities, so do we also with physicians—there are among medical men some who, in the true sense of the word are not physicians at all. Here is a type of the latter class.

One day in speaking of the importance of the **psychological factor in therapeutics** with a physician, he said, " Well, there may be something in that; for not long since I had a patient who lay in bed a little over three months, and I could not find a thing the matter with her, but I never tried to exercise any influence over my patients in any way. **They expect medicine,** and I give it to them, and let them use their own minds to suit themselves. I am not in the profession for my health, and a man is liable to **lose out with his patients** by being too dictatorial."

" **How often** did you see her, doctor? "

" Twice a day."

" And you let her stay in bed **three months,** saw her twice a day, and did not even tell her that there was no reason for her staying in bed, and **advise** that she get up and move about, take exercise, get fresh air and take an interest in the affairs of life, both as a means of happiness and for her physical well-being?"

" No, she was a **very sensitive** woman, and I hated to hurt her feelings," he replied.

"What was your bill in that case, doctor?"

" Four hundred and eighty dollars."

" And you are not afraid to hurt her feelings with that sized bill?"

"Oh, no, she was **quite well satisfied** and paid it without a murmur."

" Why, doctor, if I saw no reason for that woman staying in bed and having me visit her **twice a day** I would as leave take money from off a dead man's eyes as receive pay for such work."

" That is **just the difference** between us," said he.

And it was. And this illustrates a type of men everywhere who call themselves physicians.

Some physicians are actually convinced that they have done their duty when they have been **kind, sympathetic, and attentive** to their patients and prescribed for them medicinally. **Since their patients are satisfied** they seem to feel that they have done their whole duty. **So long as there is money in the case,** the recovery of the patient does not seem to concern them.

The absolute lack of moral courage displayed by this class of doctors, who upon the surface give the appearance of being honest and conscientious professional gentlemen, is horrible to contemplate. **They use narcotics freely,** even when contra-indicated, inhibiting the normal physiological processes, **robbing their patients of self-reliance,** rendering them absolutely dependent upon the physician, lessening in every way their resistive powers, and actually retarding recovery. **We all have seen such men** who in the spirit of cold commercialism impress by word and conduct on their patients that they are very sick, when this attitude on the physician's part has proved to be a

great causative factor in the case. Their patients, after a long illness, consider that their physician, in having impressed on them that such would be the case, has only displayed his knowledge and good judgment; whereas, in fact, this man in whom they have trusted has really been the greatest causative factor in the case.

Some physicians acquire a high reputation by giving a gloomy prognosis, thereby instilling fear into the minds of both patients and friends, bringing to bear upon them all the psychological conditions possible to depress them and hypnotize them into a long siege of illness. **The power and efficacy of suggestion,** in the cause and cure of disease, are but faintly appreciated by **one in a thousand of the people** of our time; hence their easy gullibility by such men. **The student of psychotherapeutics** can discern this class of physicians everywhere, who often stand high in the medical profession.

If I were to tell you that in a room I had a servant ever able and willing to obey my dictation or orders and execute them, in having everything in that house just as I wanted it, so could you form some idea about **the power of the great involuntary nervous system** in its control over the bodily functions. We influence this involuntary nervous system by the **sense impressions we make upon the brain plasm** of the patient whenever we come into his or her presence.

Fully nine-tenths of an individual's **psychic powers or protoplasmic energies** are subconscious; that is, he—the intellectual man—is unconscious of them. **These we can influence** for the good or harm of our patient. The physician who shakes

his head, and gives a high-sounding name of the disease, often fastens the condition stronger upon his patient, **by adding a psycho-neurotic element** when there is no pathological basis for the condition named existing.

A lady of my acquaintance had been sick for several months and her physician took with him to see her a consultant who appreciated the psychic element in therapeutics. Together in the consulting room they discussed this case.

"What is the matter with her, doctor?

"Just weak and nervous, can't sleep, does not eat, discouraged, and getting worse every day."

The consulting physician quickly saw that the attending physician was the **most aggravating causative factor** in this case.

"Why does not she get better," said he to the consultant.

"Because you don't talk and act right."

"What must I do and how should I talk?"

"Why, give her a sleeping capsule, and tell her that you are going to give her a good night's sleep. Then turn to the nurse and say, **'Give one of these sleeping capsules** at eight o'clock and if she is not sleeping soundly by nine, give her another, but **in no event** give her more than two, **she will sleep sound all night.' Say it as if you meant it.** Say it as if you had not the slightest doubt about it. **Then, turning to the patient,** say 'You are going to sleep well to-night and will feel much better in the morning.'

"When you come to see her to-morrow, smile pleasantly as you walk into the room and, as you bid her good-morning, take her hand, and feeling her pulse affirm: **'You are better.'** Tell her she will improve every day now. Say to her, 'You will en-

joy your food today and not be nervous and will feel much stronger; you are going to get well; **going right along to recovery.' Keep this up** as you see her at every visit. **Getting in behind** a neurasthenic case like this with all the bodily functions perverted, you can stir latent energies and stimulate nervous centers into activity and be a factor for good."

The physician did so and his patient was soon well.

Too many physicians are nothing more than **slaves to their own desires. They see** in their patient's illness a **chance to make money.** They feel that they have done their duty when they have prescribed for them in **a perfunctory manner** and, putting their reliance solely in drugs, they overlook entirely the psychologic factor in therapeutics. **They even tell their patients** that they are seriously sick, purely for personal aggrandizement.

The result is undue nervousness, over anxiety, sleeplessness, perverted functions and constant progress from bad to worse. These symptoms they attempt to relieve by narcotics. They enter the sick room in this indifferent, half-hearted, **selfish manner** and their efforts are worse than useless.

Such physicians forget that man is a living organism, body, mind and spirit, and the ideal ego should be **the master,** not the the slave, of the body.

See in your patient potentialities that are susceptible to external stimuli, and regard something besides the physical manifestation of the individual.

Treat the man himself, the intelligent organized force—call this mind, soul or spirit—that has simply cast this physical

cloak around him and stir him to renew, energize, vitalize and strengthen every part of his physical organism.

What do we stir? Call it what you will, let it be the "vis medicatrix naturae," the "resident energy within," "neuric energy," the "subconscious self," the "involuntary nervous system," the "psychic man," **"spirit," "mind,"** or **"soul," the name matters not. This fact is true.** Man has within him **reserve energy** that can be stirred into activity. **By suggestion the physiological processes** of the body can be influenced for his good. We can produce such impressions upon **his brain plasm** as will quiet nervousness, relieve pain, promote sleep, and acting thus, we can conserve his energy, resulting in a better appetite, better digestion, and improved nutrition. We thus re-establish all the **perverted physiological processes.** By this means you can get your patient well when drugs and other remedial agents absolutely fail.

If medicine or **surgery is indicated,** by all means use it.

The great trouble is that **many of the men** in our profession are ignorant of the potency of the psychologic factor as a therapeutic adjunct. **Some who have had a glimpse** of these latent possibilities lack the moral stamina boldly to take hold and do their part. I know men who would **face a cannon absolutely devoid of physical fear,** yet too timid and half-hearted in the sick room to do more than give drugs, nine-tenths of which are worse than useless, in this class of **functional** and **neuropathic conditions.**

Many of these sick people need a good, sound, intellectual flogging. They need to be told that they alone are to blame for

their condition. Let them know that **health is a natural condition** and comes to every one who conforms to nature's laws, which they are continually violating every day of their lives.

Emerson has well said that "Man may boast that he can violate the laws of Nature and maintain health; the lie is on his lips, the conditions on his soul."

Let your patient know that to maintain health he must conform to the laws of health. Get hold of him and put him in possession of himself. **Urge him** to take into his system plenty of Nature's healthful beverage, pure water, to eliminate impurities from his system and to encourage all functional activity. A man should not drink less than four or five pints of water a day. **Tell him or her to exercise freely** every muscle and hasten the blood to every part of his system to eliminate effete material as well as to build up, nourish and renew the life and strength of every cell in his body. **Advise him against** becoming a slave to his appetites, over eating, sexual excess, etc.

Fully nine-tenths of the American people eat **too much meat** and keep their **nervous system overtaxed** to dispose of the amount of food in excess of what is actually necessary for nutrition. Get such people, when nervous, to **learn to relax** and **to practice deep breathing** as a resource of healthfulness. Impress upon them the **pleasure, beauty** and **glory** of **work** and useful endeavor and achievement, as a means to invigorate and strengthen both mind and body. **Let them know** that we are born into this beautiful world surrounded by everything to make us happy and keep us well, but that **the world is ruled by law** and we must conform to laws of health, and that when we do that we shall

be well and happy, which is our highest privilege, and not before.

It is often the case that our patients need education and encouragement, knowledge and guidance—other names for suggestion—**and not medicine or sympathy,** which only fixes them **deeper in the mire;** but there are some who are called physicians who **have not the courage** to attempt to make use of these therapeutic measures.

Why let Christian Scientists, osteopaths and other species of charlatanism thrive upon a large class of cases when, if we were but equipped in this higher art in therapeutics, we could day by day infuse health and happiness, joy and sunshine, into the lives of weak, erring, miserable children of this world who are crying to us for help. **Our patients are not merely chemical laboratories,** but human beings with intelligent faculties to comprehend our suggestions that **act upon every part of the body through** the nervous centers. If properly presented they will regulate all perverted functions **in perfect accord with the physiological processes of the body.**

Man is not a machine, but a living organism.

The unseen part of man, mind, spirit or soul, constitute the dynamics of this human organism and they constitute the greatest therapeutic factor at our command, ever present and ready for utilization.

CHAPTER XXV.

SELF-MASTERY AS A FINE ART.

"Man exists.....not for what he can accomplish, but for what can be accomplished of him."—Goethe.

By suggestion we can add a dynamic quality to the mental equipment of an individual who is receptive. A new element is given to his personality by the impression made upon his brain plasm, which better equips him to meet the exigencies of life, and whereby he can be educated into the art of self mastery.

A little child, seven years old, was beginning her first day in school and appeared bewildered and confused as she anticipated the new experiences that the day had in store for her. As she started out of the home, her father, who was awaiting the arrival of the right psychological moment, called her to him.

"Papa, mamma says I must hurry or I shall be late," responded the child as she came up closer to find out what her father wanted.

"You have plenty of time, my daughter," said he. "I have a secret to tell you if you will promise not to give it away. Do you know there is **not a smarter child** in this town than you are?"

"No, papa, I did not know that."

"Well, there is not, and I will show you. Who can run faster than you among your little friends?"

"None of them," was her answer.

"Who rides a wheel or plays dolls better than you?"

"None," she answered.

"Well, here is our secret. They cannot learn faster in school than you can. They are all smart, but they don't know it. The girl that does what her teacher tells her is the one that learns the fastest. Now, that is our secret. You go and find out what your lesson is and come home and we will help you to study, and by the end of the term you will be at the head of your class."

The child's answer was, "All right, papa, if you will help me, yes, I will."

"Go to school now, you have plenty of time, but don't give away our secret."

The child walked away with a new element added to her consciousness. She went with head erect, and a smile on her face that indicated that she was going out to conquer. Of course, this was followed by other similar suggestions, and during the eight years since that time, that little girl has stood with the head of her classes and found in her school work a genuine pleasure.

In another instance a child, thirteen years of age, was competing for a prize given in elocution. Her father had also offered her a reward and expressed a wish that she win that medal. She had worked hard to succeed and upon the morning of the contest the father called her into his den and handed her the promised reward for winning the contest.

"But," said she, "I haven't won it yet."

"See here, daughter," was his response, "I know, and your teacher knows, that you render that selection aright. Now, it matters not one bit what the judges or the audience think of it. Go, render your selection to suit yourself and to do credit to your

teacher, but forget all about the prize or the opinion of the judges."

She went away relieved of all apparent anxiety and shared the prize with an older contestant.

The question of self-mastery is one of education and self-development. **By suggestion we can plant ideas** that give rise to impulses or incentives within the individual to make effort at self-development, self-education, and self-control.

Every one should be made to feel that he is born to be of use in the world and should be taught how to exercise his capacity, for it is only through the self-reliance gained by our own activities that we can make a success in any vocation in life. **The individual** who can be of most help to others is the one who sees the greatest possibilities within them.

The problem of life for every individual is the one of self-mastery; how best to conserve and direct our energies into useful, wholesome lines of thought and action. **To be of help to others** one must at least in some degree have become master of one's self.

It has been a matter of observation to see a physician so utterly lacking in self-control that he was incapacitated to use efficacious suggestion upon an individual, even after the latter had assumed an attitude of voluntary receptivity. In him **the self-conscious ego** had not been evolved sufficiently to give him force of character to be of influence.

It is for each one of us to decide whether we shall control and govern ourselves in the light of reason, education and ex-

perience, or be held by the opinions of others. **To do our best in life** we must be independent, strong, capable and free.

The leaders of all professions in all ages have been men who have overleaped the limitations of environment, of ignorance and superstition, and have dared to stand up for what they believed to be right.

To have achieved self-mastery is to be guided by reason, impelled by truth, and freed from the tyranny of fear, selfishness and ignorance. It denotes courage, humble service, magnanimity, sympathy, friendliness and a tenacious stand for the right. To reach this high ideal of moral attainment human evolution must go on forever. We are as yet in the *amoeba* and *moneron* stage of our appreciation of this higher conception of ourselves and our relation to others.

"With this poor life, with this mean world
I'd fain complete what in me lies;
I strive to perfect this—my me;
My sole ambition's to be wise."

Fear is the natural consequence of weakness and ignorance.

To be masters of our bodies does not mean that the physical basis of existence is to be ignored. **Far from it. On the other hand,** to maintain a strong, healthy body is the first essential to development. **Will power and determination** are natural accompaniments of a healthy organism.

There is a peculiar psychic quality that is the heritage of some individuals. They are content to drift with the crowd and have not the courage to dare to use their own reasoning faculties. **The problem of education** is to deliver these individuals

from such tendencies and thus to prevent them from lapsing into physical weaklings, mental nonentities, or moral cowards.

It is the inalienable birthright of every human being to manifest the highest expression of individuality and selfhood; to give the world **the very best** that he can make of himself according to the limitations of **heredity, environment** and **education.** Fear and selfishness are the greatest barriers to the progress of aspiring humanity.

The "thou shalt" and "thou shalt not" of an irresponsible hierarchy no longer fetters the spirit of the man who has obtained sufficient self-mastery to live up to the light and knowledge of the present age.

But not for ourselves alone must we live. We gain in strength by helping others, by assuming responsibility, by work and useful achievement.

A great deal of the hysteria and neurasthenia and despondency and weakness of men and women is due to their failure to exercise sufficient self-mastery, to use the powers and capabilities inherent within the cells of their organism. Such people we can wonderfully benefit by suggestion.

Medicine will ever have a place in our therapeutic armamentarium, **but its use** to relieve nervousness and psychoneurotic and functional disturbances, by lulling and inhibiting the normal physiological processes, **where the individual should be taught** the art of self-mastery, self-control, self-activity and conformity to such physiological methods of development as breathing, relaxation, dietetics, water drinking, exercise and work, with sunshine, fresh air and cheerfulness, **is a crime.**

The use of suggestion in therapeutics is nothing more or less than getting an individual to exercise self-mastery and self-control.

Here I am reminded of a stalwart man, six feet two inches high, weighing one hundred and ninety-eight pounds, who had a wife and two children in another portion of his State, while he was being supported by his brother, and all the while nursing and encouraging a psycho-neurotic condition. **His physician informed me of this element** of sloth and laziness that was a great factor in his case, besides his morbid self-consciousness, and sought my aid to arouse him from such psychic incumbrances and put him in possession of himself.

He came into the office walking upon a cane, and besides his symptoms of indigestion and insomnia, he complained of a constantly painful and weak back.

Our treatment was to give such suggestions as to drive back his morbid existing sense impressions. To substitute a new consciousness he was placed with head on one chair and heels on another and made to sustain my weight of 200 pounds upon his body. **Then, looking him in the face,** after he was awakened, I imformed him frankly and honestly of the test we had made and assured him that a stronger man did not exist in his State, that all he needed was exercise, and that the right thing for him to do **was to go to work. I met him upon his own plane,** that of a physical laborer, and used such methods as would most convince him that he was a man, **and he appreciated it.** He did go to work and had no farther trouble.

Such harsh treatment is not applicable in private practice, but when I see people whining and complaining and morbidly self-conscious of their own life's battles, I can but wish that they could be aroused in some way and be made to see the pleasure and beauty and glory of work.

Upon the exercise of our own self-activity does the welfare of the future race depend.

The intellectual world brings life's greatest pleasures, but as we now understand it, the head and hands must be educated together. Mental and physical development must go hand in hand.

When wealth causes the individual to depend upon the physical and mental efforts of others to do for him what he should do for himself, it is a means of degeneration and weakness.

It is all a question of mental attitude. We must ever press onward for the acquirement of more knowledge, the discovery of new truths, and for facts revealed by new experiences. We must never be willing to accept as a finality the imperfection of present attainments.

To be glad to live for life's own sake, to love and to help others for the pleasure it gives us, and in our own humble way to crown our lives with useful endeavor and achievement, leaves no excuse for the question, Is life worth while?

It never becomes stale, flat and unprofitable, save as it reflects our own stupidity.

THE DIAGNOSIS AND TREATMENT OF DISEASES OF WOMEN

By H. S. CROSSEN, M. D.

Clinical Professor of Gynecology, Medical Department,
Washington University, St. Louis.

816 Pages. 700 Illustrations. Price, cloth, $6.00; morocco, $7.50.

Sent anywhere prepaid upon receipt of price.

NEW YORK MEDICAL JOURNAL: "This is one of the best works on Gyneacology that we have ever seen. It owes its excellence chiefly, we think, to the fact that its author is able to think of something besides operative measures, showing no contempt for pessaries, but giving indeed a true exposition of their modus operandi and a reasonable rating of their value. The book is strong, however, even in the matter of operations, as is shown in the masterly statements concerning the numerous operations for retroversion of the uterus. Another feature which makes the book of immense value to the general practitioner and to the comparatively inexperienced specialist in Gynaecology is the amount of attention given to diagnosis, to which 308 pages are devoted."

PROVIDENCE MEDICAL JOURNAL: "It is most emphatically the helpmeet of the intelligent General Practitioner, and serves to place before him in a compact and forceful manner the main facts of diagnostic value and to point out the proper therapeutic indications. The manner of exhibiting the remedies applicable to a given condition is carefully set forth and the reason for this usefulness explained. The section on pessaries is of particular value and will be warmly welcomed by the profession, which has long labored under a hazy impression of the proper indication for the use of pessaries, and the principles involved in their selection and application. The author's discussion of retrodisplacements of the uterus is also worthy of particular mention, as setting forth in a simple yet striking manner the cause and treatment, non-operative and operative, of this frequent and badly treated condition. The 700 illustrations scattered throughout the volume are excellent in character and very materially enhance its value."

HOWARD A. KELLY: "It will surely meet the needs of the general practitioner and student, as well as specialist. You have taken such pains to be explicit in so many details of our art."

TODD GILLIAM: "After a careful and much interested examination of your work on gynecology, I want to congratulate you on the text, illustration, arrangement and mechanical make-up of the book. It is unique in its way, and has a field of its own."

DR. ROBERT L. DICKINSON: "You are simple, and practical, and clear That is what men want."

Diseases of the Skin

...BY...

A. H. OHMANN-DUMESNIL, A. M., M. E., M. D., Ph. D., etc.

Formerly Professor of Dermatology and Syphilology in the St. Louis College for Medical Practitioners; the St. Louis College of Physicians and Surgeons; the Marion-Sims College of Medicine; Member of the St. Louis Medical Society, of the Missouri State Medical Association, of the American Medical Association, of the 1st, 2d, 3d, 4th, 5th and 6th International Dermatological Congress, etc.

THIRD EDITION

THOROUGHLY REVISED AND ENLARGED

150 ORIGINAL ILLUSTRATIONS

600 PAGES. PRICE: CLOTH, $4.00. MOROCCO, $5.50.

PREFACE

This book is not a treatise. The intention has been to make of it a practical guide to the easy recognition of skin diseases, as well as to their successful treatment. The remedies which have been recommended are such as may be found in every practitian's armamentarium medicinorum. No attempt has been made to write an elaborate work, but rather to furnish, in a clear, concise manner, just that information most desired by medical students and general practitioners.

TABLE OF CONTENTS.

Chapter I. The Skin.
Chapter II. Anatomy.
Chapter III. Physiology.
Chapter IV. Diagnosis.
Chapter V. Etiology.
Chapter VI. Pathology.
Chapter VII. Therapeutics.
Chapter VIII. Prognosis.
Chapter IX. Symptomatology.
Chapter X. Classification.
Chapter XI. Diet in Skin Diseases.
Chapter XII. Food Eruptions.
Chapter XIII. Appendix.

EMILE COUÉ

the steadfast Worker and Pioneer

TRANSLATORS' PREFACE

THE dissociation of hypnotism from mysticism and superstition was efficiently begun by two investigators, Alexandre Bertrand and James Braid. Bertrand (*Traité du somnambulisme*, Paris, 1823; *Du magnétisme animal en France*, Paris, 1826) insisted especially upon the psychological determinants of the phenomena in question. He maintained that what we now call the hypnotic state was brought about through the influence of the imagination of the patients acting upon themselves. Herein we have the germ of Coué's theory of autosuggestion as expounded in the following pages. Braid, on the other hand (various writings, from 1841 to his death in 1860), inclined at the outset rather to the physiological explanation of what he was the first to term "hypnotism." It is interesting to note that Braid was a pioneer in the therapeutic use of reflective autosuggestion. He describes his own sufferings, in September, 1844, from a severe attack of muscular rheumatism, which had made it impossible for him to sleep for three successive nights. He then hypnotized himself in the presence of two friends. "At the expiration of nine minutes they aroused me, and, to my agreeable surprise, I was quite free from pain, being able to move in any way with perfect ease. . . . I had seen like results with many patients; but it is one thing to hear of pain, and another to feel it. My suffering was so exquisite that I could not imagine anyone else ever suffered so intensely

as myself on that occasion; and therefore I merely expected mitigation, so that I was truly and agreeably surprised to find myself quite free from pain. . . . A week thereafter I had a slight return, which I removed by hypnotizing myself once more; and I have remained quite free from rheumatism ever since, now nearly six years." The observation is quoted by Arthur Edward Waite in his biographical introduction to *Braid on Hypnotism* (pp. 45-6). To the contemporary reader, and above all to students of Coué and Baudouin, it is obvious that the essential feature in the cure was not the "hypnotism" but the autosuggestion.

Yet the idea that unconscious autosuggestion is responsible for many of our troubles, moral and physical, was slow to mature. Even to-day, people fail to recognize that they are largely wrong when they speak of " the ills that flesh is heir to," and that they should rather in many cases speak of " the ills that fancy breeds." Still more slowly has come the recognition that in reflective autosuggestion, scientifically applied, we have in very truth the faith that moves mountains. Healers, official and unofficial, have at all times made use of the power of suggestion, but the use has been for the most part unconscious. James Goodhart, in his Harveian lectures on *Common Neuroses* (1894, p. 129), tells us that " there are many conditions in which the cure must come mainly from within, our function in chief being to call out this dormant power." But for Goodhart the " rational treatment " of disease was still to be found in skilled advice as to regimen and the like; the " dormant power " of reflective autosuggestion was not yet revealed to his discerning gaze. In the most outstanding British work on psychotherapeutics, J. Milne

Bramwell's *Hypnotism* (third edition, 1913), the word autosuggestion is not to be found in the index. Yet Bramwell inclines to accept the theory that the phenomena of hypnotism are chiefly explicable by the conception of "the subliminal consciousness," and he records as the main feature of this theory that "the essential characteristic of the hypnotic state is the subject's power over his own organism." Here we obviously verge upon Coué's teaching. But the affiliations of that teaching can be best understood in the light of a brief analysis of the development of the theory of hypnotism subsequent to the days of Bertrand and Braid.

Substantially, it may be said that the theory of the psychological determination of these phenomena now holds the field. Heidenhain and others cultivated the physiological theory with vigour, and for a time with success. Charcot and the Salpêtrière school maintained that the phenomena of hypnotism were mainly, if not exclusively, morbid; that they were manifestations of major hysteria or hystero-epilepsy. But by serious investigators to-day it is generally admitted that the views of the Nancy school, the views of Liébault and Bernheim, represent the truth, and that the pathological theory of hypnotism now possesses no more than historical interest. For twenty years A. A. Liébault practised hypnotism at Nancy, having a gratuitous clinic for his poorer patients. He rediscovered that expectation is the primary factor in the causation of hypnotism, that increased susceptibility is the leading characteristic of the hypnotic state, and that the suggester's influence upon his subjects is exerted through mental rather than through bodily channels. Hippolyte Bernheim, professor of medicine at Nancy, was the philosophical ex-

pounder of these theories, and it is with the name of Bernheim (died in 1919, at the age of eighty) that the ideas of the first Nancy school are especially associated. Edouard Coué, as Charles Baudouin explains in his preface, has like Liébault devoted many of his best years to the practice of psychotherapeutics in a free clinic, for a time at Troyes and subsequently at Nancy. Baudouin is the first great theoretical exponent of Coué's teaching. He bears much the same relationship to Coué that Bernheim bore to Liébault. He and Coué will speak for themselves throughout the present volume. Enough here to insist on three of the most essential and novel features in the teaching of the New Nancy School:

1. The main factor in hypnotic phenomena is not heterosuggestion but autosuggestion; and, as a corollary, the chief advantages of psychotherapeutics can be secured without a suggester and without the more salient features of the hypnotic state.

2. Of fundamental importance to success is what Coué terms "the law of reversed effort," the law that so long as the imagination is adverse, so long as a countersuggestion is at work, effort of the conscious will acts by contraries. We must think rightly, or rather must imagine rightly, before we can will rightly. In a word, our formula must not be, "who wills can"; but "who thinks can" or "who imagines can."

3. The most significant phenomena of autosuggestion occur in the domain of the subconscious (unconscious). The new powers which autosuggestion offers to mankind are based upon the acquirement of a reflective control of the operations of the subconscious. Herein, as Baudouin shows in his Preface and his Conclusion, the teachings of the New Nancy School at once confirm and

supplement the theories of the Freudians and the data of psychoanalysis.

In the subtitle of *Suggestion and Autosuggestion* we are told that it is a "psychological and pedagogical study." The educational applications of the teachings of the New Nancy School are, if possible, of even greater interest and importance than the curative applications. It is not always easy to separate the two categories, for from a wide outlook the mentality of the majority of "normal" human beings, the products of what passes to-day by the name of education and the outcome of the suggestions of our exceedingly rudimentary social environment, may be said to have an essentially morbid quality and to need all the relief that can possibly be given by the healing art. Consequently the apostles of the new psychology, the Freudians equally with the pupils of the New Nancy School, are educationists as well as therapeutists. We find a whole section on "Education and Child-Study" in Ernest Jones's *Psychoanalysis;* while the American writer, Wilfrid Lay, has recently supplemented his volume *Man's Unconscious Conflict* by a work devoted to the educational side of Freudianism, and entitled *The Child's Unconscious Mind.* But the implications of Coué's practical discoveries and of Baudouin's theories are destined to influence educational work more radically even than Freudianism can influence it. Intelligent educationists have long recognized that a large proportion of the effects of education, good or bad, are due to suggestion; but a few years ago M. W. Keatinge, in his volume *Suggestion in Education* (first edition 1907, second edition 1911) criticized the term autosuggestion as mislead-

ing. He wrote, " the idea is really suggested from without, and appears to be 'self-suggested' only to the person in whose mind it has been latent." Nevertheless, most careful readers of Baudouin's book will we think agree that in education, as in psychotherapeutics, what goes on in the subject's subconscious is what really counts in the whole process, and that upon the successful appeal to the subconscious largely depends the success of the teacher no less than the success of the healer. Educational theory will have to be wholly reconsidered in the light of the doctrine of autosuggestion as taught at Nancy and at the Jean Jacques Rousseau Institute in Geneva. A careful examination of the successes of the latest educational methods, like those of Maria Montessori and those of Faria de Vasconcellos (*A New School in Belgium,* London, 1919), will show that their value is in large part due to an unwitting appeal to the subconscious, and to a skilful though not as yet fully understood utilization of the pupils' powers of autosuggestion.

As for the philosophical, psychological, and ethical implications of the new doctrine, yet more interesting (to persons interested in such abstractions) than its bearings upon pedagogy and upon therapeutics, it is not for the translators to add a word here to what Baudouin writes in his eloquent Conclusion on " Suggestion and the Will." Those who like to know whither they are being led, may usefully read this brief philosophical section before approaching the preliminary problem "What is Suggestion." In our opinion the Conclusion is equally valuable as a preamble to the Introduction, and might be read first as well as last. For, after making that intimate acquaintanceship with *Suggestion and*

Autosuggestion which is one of the privileges of a translator, we unhesitatingly endorse the author's claim that the teachings of the New Nancy School are destined, in conjunction with the teachings of psychoanalysis, to effect a renovation of psychology, medicine, and pedagogy. As supplements to Bergsonianism the two will probably achieve the renovation of philosophy as well.

EDEN AND CEDAR PAUL.

London, May, 1920.

AUTHOR'S PREFACE

SINCE the year 1910 there has been in progress at Nancy a psychological and medico-pedagogical movement which we are entitled to regard as one of the notable scientific happenings of the present epoch.[1] The terms autosuggestion, the education of the will, the force of thought, self-control, have long been current. But with the rise of the New Nancy School we have for the first time the elements of a really methodical synthesis of the phenomena and the disciplines which these terms connote.

The pioneer in this development is a man whose devotion is rivalled by his modesty. During the years 1885 and 1886, Emile Coué witnessed the work and the experiments of Liébault, who was, as everyone knows, the father of the doctrine of suggestion, the founder of the first Nancy school, and the teacher of Bernheim. Subsequently, Coué, whose financial resources were slender, had to devote most of his energies to gaining a livelihood; but, like all men whose minds are dominated by an idea, he went on working unremittingly in silence and alone. He studied the further developments of the Nancy principles in the United States, and was able to extract from the new theories such serious, practical, and solid content as they possessed. But he brushed aside

[1] The presence of the enemy at the gates of Nancy imposed inevitable hindrances to the work, but did not interrupt it completely. Herein is a sign of vitality.

all that was nothing better than puffery and humbug, and he likewise rejected the mystical postulates which underlay some of the theories. By the closing years of the nineteenth century, Coué had grasped the thought of which he was in search. He discovered in autosuggestion the powerful and widely diffused force of which hypnotic suggestion, the only form of suggestion hitherto studied in medicine, is but one among many applications. Through repeated experiments he was further able to show that this force was efficacious in troubles that were manifestly organic; and he proved that the education of the force, which though often confused with the will is quite distinct from the will, is a simple matter and within the competence of all. Contemporaneously with but independently of the idea of psychoanalysis (developed along divergent lines by Breuer and Freud, on the one hand, and by the Zurich school, on the other), the idea of the New Nancy School, clearer than the former and more akin to the French spirit, leads us, by a path parallel with that opened by psychoanalysis, into the little-known domain of the subconscious, and contributes likewise to the renovation of psychology, medicine, and pedagogy. The two outlooks are complementary.

By his perfect disinterestedness, by the establishment of a free clinic, Coué has been able to extend his experience to far wider limits than those known to most practitioners.[1] In this way his energies were directed more and more into the practical field, were monopolized, if I may use the phrase, by the apostolate of action. He has written no more than a few articles in the bulletin of

[1] During the months preceding the outbreak of the war he was consulted by more than one hundred persons daily, so that the annual average of consultations would have been 40,000.

the school,[1] and some papers for psychological congresses.[2] Even scantier are the writings of his pupils. The New Nancy School supplies the elements of an entire psychology, but this psychology remains unwritten. It has therefore seemed to me that it would be serviceable to attempt the presentation of a first coördinated outlook, however incomplete, upon questions whose theoretical and practical interest is of so high an order. Preeminently I have assumed the pedagogical standpoint;[3] that is to say, I have attempted to show how, by a simple process of education, a latent power may be made kinetic. It is this transformation, above all, that is important.

But on the threshold of my work, I wish to pay due homage to the founder of the New Nancy School, to the beloved teacher to whom these pages owe the best part of their substance, to the man but for whom they would never have been written.

CHARLES BAUDOUIN.

INTRODUCTION

WHAT IS SUGGESTION?

WHEN we speak of suggestion, our first difficulty is to come to an agreement as to the meaning of the term. Furthermore, questions of words are at the same time questions of things; a definition is a theory.

It may be true that the meaning of the term suggestion is still somewhat vague; but this does not give anyone the right to formulate a purely arbitrary definition, haphazard. For by now, in the language universally accepted by science, the word has come to be applied to precise and well-known facts, and a definition which should fail to take these facts into the reckoning would be inadmissible.

We have to ask whether all the facts, or a very large majority of them, exhibit a common specific character. If this be so, then wherever such a character is encountered, we are entitled to speak of suggestion.

Among the phenomena universally recognized as belonging to the domain of suggestion, two groups of very different type have drawn the attention of various observers, some persons inclining especially to the study of one group, and others to the study of the other. We have to ascertain which of these two groups is the most characteristic, and which we should therefore choose in drawing up our definition of suggestion.

A subject is hypnotized, and the operator orders him

to look at an imaginary bird: the subject has the suggested hallucination. Or, on the other hand, a doctor may cure his patient by a simple affirmation of cure.— In each of these experiments, two phases can be distinguished:

1. An idea,[1] proposed or imposed by the operator, is accepted by the mind of the subject.

2. This idea undergoes transformation into an action, so that the object of the idea (in the instances given the hallucination or the cure) is realized.

These two phases recur in all the phenomena which it is generally agreed to regard as suggestive. But which of the two is essentially and truly characteristic? Here comes the divergence of opinion.

Public opinion gives its verdict for the first phase. Suggestion, for public opinion, has as a fundamental requirement two terms, an operator and a subject. It consists in the forcible control of the comparatively feeble will of the subject by the comparatively powerful will of the operator.

The domination will be facilitated by a peculiar state known as hypnosis, and it is through the combined influence of domination and hypnosis that we arrive at the second phase, the realization of the idea.

These strange realizations, so astounding in their accuracy, which hypnotism has revealed to us, could not (it is contended) be brought about in default of certain peculiar conditions of which the leading condition is the presence of a suggester.

[1] The term "idea" will be used here in the widest sense of "representation," and will denote the image as well as the concept.

The theory just expounded is invalidated by the facts.

To settle the question decisively let us ask what are the profoundest changes which the suggestion of an operator can produce in a hypnotized subject, and let us see whether an *isolated* subject can, unaided, produce similar changes in himself.

To clear up this point we may consult one among the practitioners who have done most to widen "the frontiers of hypnosis," Bonjour of Lausanne. Let us examine the maximum result he has secured.[1]

A matter of outstanding interest is the regulation of childbirth by hypnotic suggestion :

" I wished to ascertain what part the brain could play in the production of childbirth. Various theories have been propounded on this subject, but none of them take account of the action of the nervous system. Why is a child born on any particular day instead of on the following day? Why do deliveries take place more frequently by night than by day? I have advanced a theory which lays stress on the accentuation of internal sensations during sleep ; the discharge of the nervous and muscular mechanism which lead to the delivery is analogous, in my opinion, to what we see in dreams. During sleep, some trifling sensation from the periphery (in the case now under consideration, from the uterus) or from the brain (dream) is exaggerated by the brain and sets at work the automatic centres in the medulla, which arouse the uterus to contraction. If my theory

[1] Cf. Bonjour, passim. More particularly, Une preuve nouvelle de l'influence du psychique sur le physique, Communication faite au troisième congrès international de psychologie et de psychothérapie à Munich.

were sound, it should be possible, I held, to establish its truth by the use of hypnotism.

"Professor Rapin, who was at this time chief of the maternity hospital and to whom I had spoken of the matter, begged me to make the experiment in his wards. He selected a young woman whose confinement was due three weeks later. This was on a Tuesday, and I proposed to arrange for the successful fulfilment of the experiment on Friday. There were, therefore, but three days for preparation.

"Nevertheless I felt sure that the desired result would be secured, for my observations had absolutely convinced me of the part played by the brain in determining the time of delivery.

"I suggested to the young woman that she should fall asleep on the Thursday at two o'clock, that the labour should begin during the night of Thursday-Friday. I told her that I should come at seven o'clock in the morning of Friday and that the child would be born at noon.

"On Thursday at four in the afternoon I went to the maternity hospital. The patient had fallen into a profound sleep at five minutes past two, though her companions had vainly endeavoured to prevent her. I again told her how I had regulated the course of events, and left her with an order that she should no longer hear any voices except those of Professor Rapin and his assistant.

"The following day I did not reach the hospital until half-past nine instead of seven o'clock, this putting things back by two and a half hours. The woman told me that throughout the night she had been aware of the sensations I had suggested. The obstetric assistant declared that labour had not yet begun, and my own exami-

nation confirmed this statement. But I was convinced of the reality of the woman's own sensations. They were the outcome of suggestion, and I could increase them at will. This is what actually happened. After suggestions had been continued for a quarter of an hour, the neuromuscular machinery was at work, and by the time when Professor Rapin arrived at eleven I was satisfied that my experiment was succeeding. He asked me to demonstrate the case to the students. I had not expected this complication, but I knew that nothing could now interfere with the successful issue, and I agreed. After the clinical lecture, Professor Rapin and I went down into the town, he, convinced that the child would not be born for three or four weeks, and I myself satisfied that all the phenomena of impending delivery corresponded to what I had desired to produce by suggestion. I had hardly finished lunch when I was summoned to the hospital. By half-past three labour was over, and I reawakened the young woman, who till then was not aware that her baby had been born."[1]

But the chief importance of Bonjour's work is that he has clearly shown the power of suggestion in organic disease, whereas Bernheim believed that suggestion was solely efficacious in functional disorders.

Bonjour studied the part played by suggestion in the curing of warts. As the result of numerous observations he came to the conclusion that in about half the cases warts can be cured by a single sitting in which suggestion is practised for two minutes.

The cure of a wart is a trifling matter, but a little thing may have weighty implications. The definite proof

[1] Bonjour, Guérisons miraculeuses modernes, Baillière, Paris, 1913.

that suggestive treatment can be efficacious in disease that is not purely functional was a discovery of considerable importance.

Bonjour passed on to study the suggestive treatment of other organic maladies. For instance, one of his patients was suffering from a corneal ulcer which, had it proved intractable, would have caused blindness. It was completely cured under hypnotic treatment.[1]

Modifications in an important and complicated mechanism like the mechanism of childbirth, and, on the other hand, organic modifications—here we find the maximum of which we were in search. Now if an isolated subject, without hypnotism and in the absence of a suggester, can present analogous phenomena, if, that is to say, the subject's own thought can in certain instances bring about similar modifications, we shall be obliged to conclude that the essential and characteristic element in the process of suggestion is the second phase (the transformation of the idea into action) and not the first phase (the acceptance of the idea suggested by another).

That this is actually so, the reader will learn from the facts analyzed in the following pages.

He will see how the idea of an organic modification can produce that modification in the individual who thinks the idea. He will see that this action of the idea may be more powerful and more widespread in an isolated subject than in a hypnotized subject, and that autosuggestion is really the prototype of all suggestion.

[1] Cf. the cases reported by Auguste Forel in his Hypnotism, English translation by H. W. Armit, Rebman, London, 1906. Among other cases, this author records one of strabismus and hemeralopia due to organic trouble, in which great improvement followed upon suggestive treatment.

The conclusion must therefore be drawn that the presence of a suggester is not essential to suggestion; it is enough to have a subject. In other words, suggestion cannot be defined as a phenomenon of transference wherein the starting-point is the consciousness of the operator and the terminus the consciousness of the subject. It must be defined as a work which proceeds wholly within the subject. If we do not allow ourselves to be repelled by barbarisms, we may find it convenient to say that suggestion is not an "inter-individual" phenomenon but an "intra-individual" phenomenon. Once for all, we must distinguish between the idea of suggestion and the idea of submission, of dependence upon another's will. We must not confound suggestion with subjection.

We have now to examine an objection which is well stated by Binet in the beginning of his book *La suggestibilité* (Paris, 1900). He writes as follows:

"We must obviously regard as erroneous the opinion of many investigators who look upon suggestion as an 'idea which undergoes transformation into an action.' On this theory, suggestion would be confounded with the association of ideas and with mental phenomena in general. The term would be almost meaningless, for the transformation of an idea into an action is a psychological phenomenon which manifests itself whenever an idea becomes sufficiently powerful. In the narrower signification of the term, in what we may call its technical meaning, suggestion is a moral pressure exercised by one person on another. The pressure is moral, by which we mean that it is not a purely physical operation, but an influence which acts through ideas, through the instru-

mentality of concepts, emotions, and volitions. In most cases, the spoken word is the means by which this influence is conveyed, and a definite command furnishes the best example of the kind."

In a word, for Binet the first phase of the above-described process is the characteristic phenomenon, whereas for us the second phase is the essential one.

The chief reason why Binet holds the view he does, is that to define suggestion as "an idea which undergoes transformation into an action" makes the signification of the term too wide. The word is thereby applied to a great number of well-known facts for which no new name is required.

Binet's criticism is well founded, but the definition which he proposes is open to the same objection, and perhaps to a still greater degree. He considers that a definite command is the typical suggestion. A few pages further on, in conformity with this view, he treats as absolutely identical the words "suggestibility" and "obedience."

The truth is that this definition, "Suggestion is an idea which undergoes transformation into an action," is erroneous because it is incomplete. We do not need to supply an entirely new definition, but to add what is lacking.

It will suffice to appeal to a characteristic which is plainly manifest in the simplest phenomena of suggestion. The characteristic in question is that the realization of the idea is brought about by subconscious activity, is effected without the subject's being aware of it. The idea of cure is proposed to the subject's mind, and the cure is realized without the subject's knowing how. An action is suggested to the subject during induced sleep,

and the subject is told that the action is to be performed some hours later. The action duly takes place, sometimes without any consciousness on the part of the subject. More frequently, however, the subject knows he is performing the action but is unaware of the true motive. In like manner, in the case of childbirth recorded by Bonjour, the extensive work which culminated in the realization of the idea went on outside the subject's consciousness. The subject only became aware of the result after everything was over and when informed of the fact by others.

In the case of autosuggestion, it is precisely this unawareness which enables us to distinguish the phenomenon from an ordinary act of volition, from one wherein the subject realizes his idea through conscious effort and while uninterruptedly supervising the work of performance.

Thus suggestion may be briefly defined as *the subconscious realization of an idea.*

In addition to the reasons already given, the foregoing definition of suggestion is useful on theoretical grounds.

The mastery of one will by another, the act of domination with which some wish to identify suggestion, is far from being a simple psychological phenomenon, an instance of the working of a single law. It is the resultant of numerous causes, known or unknown, and extremely complex. The first of these causes is the "personal influence" of the operator. Next, on the part of the subject, we have the "affective rapport" between the subject and the operator. This relationship may be one of love; it may be one of fear; it may be one wherein love and fear are variously mingled.

On the other hand, if suggestion be defined as we propose, its working becomes subordinated to a psychological law which is comparatively simple, and whose principle is well known even though all its applications may not be familiar. This law is the one revealed by experiments with Chevreul's pendulum,[1] the law in accordance with which the idea tends to realize itself spontaneously. Henceforward suggestion, acting in accordance with a simple law, can be looked upon as a "force" in the scientific sense of this word. Suggestion is the putting into operation, by ourselves or by another, of the ideo-reflex power which exists in us all. (See below, Part III, Chapter II.)

No longer, then, need we look upon suggestion as indicating impotence and inferiority on the part of the subject. In essence, it is a power which, by accident and in special cases, may be used against us.

It was in such instances that suggestion was first seen at work. In like manner, electricity was first seen at work in the form of lightning, before man had learned to turn its powers to account as an illuminant or as a means of transport. The task before us now is to make a good use of suggestion, considering it as one of the natural forces, and looking upon it, not as a power for dominating others, but as an instrument for self-mastery.

What has been written above shows that suggestion exhibits itself under numerous forms. Hence, classification is necessary.

The first thought which arises in this connection is to distinguish between autosuggestion and heterosugges-

[1] M. E. Chevreul, De la baguette divinatoire, du pendule dit explorateur et des tables tournantes, Paris, 1854.

tion, according as the ideoreflex power has been put into operation by ourselves or by some one else.

There need not be any essential difference between the working of these two sorts of suggestion, just as there is no essential difference in the growth of a plant when I plant it and when the gardener plants it. But the distinction is none the less important, seeing that I shall have to invoke the gardener's aid in so far as I am myself ignorant of gardening.

But in respect of autosuggestions we may make a distinction that is perhaps even more important from the theoretical outlook. As we shall learn, there is a psychological condition prerequisite to all autosuggestion. This is that the idea should have a notable intensity, an intensity which is mainly the outcome of attention. An idea upon which attention is peculiarly concentrated, is an idea which tends to realize itself.

We shall find, therefore, in the psychology of attention, a principle for the classification of autosuggestions. Ribot rightly distinguishes between spontaneous attention and voluntary attention. The former, the only variety, or almost the only variety, of attention in the lower animals, in savages, and in young children, is directed towards everything which interests us, towards everything which helps or hinders us in our aims. The latter presupposes reflection and conscious effort. Spontaneous attention is displayed by us when our eye is caught by a striking colour. We show voluntary attention when we deliberately set ourselves to solve a problem.

In like manner, we shall distinguish among autosuggestions, spontaneous suggestion, and reflective or voluntary suggestion, according as the preliminary act of

attention has been spontaneous on the one hand or voluntary on the other. This distinction is comparable to that between wild plants and cultivated plants.

We have, therefore, three kinds of suggestion:

1. spontaneous suggestion
2. reflective suggestion [1] } = autosuggestion
3. induced suggestion = heterosuggestion

We shall devote ourselves to the study of all of these. The education of the ideoreflex power, its training by oneself or by others, will be considered in the second and third parts. We shall be chiefly concerned with this education, for our outlook in the present volume is mainly practical. Part I may be considered as an indispensable introduction to Parts II and III.

But before entering into the heart of the subject, let us briefly complete the definition of suggestion given above by showing what are the relationships between the narrower sense in which we employ this term in psychology, and the wider sense wherein it is used in current speech.

Etymologically, to suggest signifies, to bring in surreptitiously, to bring in from beneath. In the wider sense, suggestion implies the *surreptitious* appearance of sentiments, ideas, actions, in a word of all the modifications that occur in our consciousness. The process resembles that by which fresh air enters a room unnoticed beneath a closed door. A thing is suggested to us when it enters

[1] The reader will learn later (Part II, Chapter I) why it is better to speak of reflective suggestion rather than of voluntary suggestion.

our consciousness without conscious effort on our part and sometimes in defiance of our will. It takes its rise in the work of our unconscious or subconscious self.

In this wider signification, we may say that a picture suggests to us a sentiment or a memory. We feel that the picture is the cause, the "occasional cause" as Malebranche would have said, of the memory or the sentiment. But the deeper cause is to be found in unconscious or subconscious work whose existence we can merely suspect. Something has been stirred in the depths of our personality. Thus, suggested states are contrasted with states to the production of which our will has contributed. They are effects whereof we neither see nor know the cause; they are like springs welling forth from the ground.

To help us to pass from this wider sense to the narrower sense of the word, let us now make the following hypothesis. At a higher level than the spring, a river has become engulfed beneath the soil as happens to certain streams in the Jura district. We realize that the spring is the same stream coming to light once more after flowing underground. A leaf which falls into the stream just as it is about to disappear, or one which we deliberately throw into the stream, will emerge at the spring, after it has been faithfully transported by the hidden stream through a region where no one could seize it in passing.

Thus an idea which has been introduced into the mind, or one which we have ourselves voluntarily introduced, will produce its effect as the sequel of subconscious activities and at the close of a shorter or longer period.

That is what is meant by suggestion as we understand it, in the technical sense of the term. Between this tech-

nical sense and the wider sense given to the word in everyday speech there is a difference analogous to that which exists between "force" in common parlance, and "force" as understood by physicists. There is no radical difference between the latter and the former, but in the technical use of the term we have less extension and greater precision.

It is well that this should be so, and that a word, when it passes from current use into technical use, should remain faithful to its derivation and to the genius of language.

PART ONE

SPONTANEOUS SUGGESTION

CHAPTER ONE

WHY DO WE IGNORE AUTOSUGGESTION?

A KNOWLEDGE of spontaneous suggestion is the necessary foundation for all reflective suggestion. We can resist or correct nature only in proportion as we are able to make a stand against nature by the use of nature's own weapons; in a word, by imitating nature. And we can only imitate nature in so far as we know her. Now autosuggestion, in its spontaneous form, is a natural phenomenon of our mental life, as natural as the phenomenon termed emotion, or the phenomenon termed idea. Moreover, the former phenomenon occurs just as frequently as either of the two latter. These statements are true although we do not play upon words, although we refrain from extending the significance of the term suggestion until it comes to denote (as in the usage of some writers) emotion and the association of ideas. For our part, we have been careful at the outset to restrict its meaning, and we shall sedulously avoid using it in any wider sense.

But if autosuggestion be a phenomenon of everyday experience, and if it be one which goes on within us, why is it so often overlooked, and why does its discovery come with the force of a revelation? There are numerous reasons.

1. In the first place, let the reader recall the definition of suggestion. He will remember that suggestion is a phenomenon exhibiting three phases:

First phase, the idea of a modification;

Second phase, the work of realization, performed unconsciously as far as the actual ego is concerned;

Third phase, the appearance of the modification that has been thought.

Now the second phase occurs without our being aware of it. Here, then, we have a causal chain whose two ends are within our grasp, but whose centre eludes us. Not without a certain amount of reflection can we convince ourselves that the ends we hold belong to the same chain.

2. On the other hand, this reflection is, from the nature of the case, absent from our habitual suggestions; for these are, above all, spontaneous phenomena. Examples to be subsequently given will make the reader understand more clearly the extent to which suggestion, in its natural form, is free from conscious effort. But inasmuch as we have said that an act of spontaneous attention is the starting-point of spontaneous suggestion, it will suffice for the moment if the reader will bear in mind how little such an act, which takes place without conscious effort, is likely to leave deep traces in the memory, or to arouse, retrospectively, reflection. Doubtless the object which attracts my spontaneous attention, the light which dazzles me, the melody which fascinates me, are graven in my memory with an intensity proportional to the keenness of my attention. But the act of perception, the mechanism of my awakening attention—what trace will that have left? I was absorbed in the act of contemplation. Like Condillac's statue, which had become "the scent of a rose,"[1] I was for the moment

[1] Condillac, Traité des sensations, Amsterdam, Paris, and London, 1754.

nothing more than the light or the melody. The perceiving subject had vanished before the intensity of the perceived object, and some difficulty is experienced in observing what was passing at the moment in the subject. Thus the second phase of suggestion eludes consciousness, while the first phase eludes observation.

3. There is an additional reason for our ignorance. Autosuggestion can operate upon us with incalculable power. Now if we permit this force to work spontaneously, in default of rational guidance, disastrous consequences may ensue, and do in fact often ensue. A large number of illnesses arise from this cause alone. Even in the case of morbid phenomena whose cause is obviously physical, it frequently happens among persons (and they form the enormous majority) who do not understand the mechanism of spontaneous suggestion, that this force considerably aggravates the malady. But if by our own insight or with the help of others we discover that we have been the architects of our own sufferings, we are extremely loath to admit so humiliating a truth. In fact we refuse to admit it, and directly the discovery presses upon our consciousness, there ensues what psychoanalysts have termed *repression,* the phenomenon whereby we are induced to forget the very reasons which have led us to the dreaded conclusion. This foolish vanity is far from being exceptional. Those who protest most energetically that they know naught of it, are often most completely enthralled by it, and their protests are nothing more than one of the numerous artifices which the censor employs to fool the consciousness. The same remark applies to the protests of persons who declare that they have never been the victims of unfortunate autosuggestions. We have all suffered in this

way, and especially those who regard themselves as immune.

These three reasons suffice to explain why we have remained so completely ignorant of phenomena which concern us so deeply. In ultimate analysis, every one of these reasons proves to be a manifestation of the activity of the "subconscious" or the "unconscious." Every one of them is a manifestation of the mental activity which goes on in us without our being aware of it. They are part of the furniture of that back shop of the mind; they belong to that life which goes on in the wings instead of on the stage; they are part of that world filled with a strangely vigorous activity, the world in which thought and action continue during sleep. The life of this underworld controls us unceasingly. It leads us at hazard, so long as we lack the clues. But it discloses to us good roads—as soon as we know them well enough to choose our way. Such is the knowledge we hope to acquire in the course of the following pages.

CHAPTER TWO

TYPICAL EXAMPLES

BEFORE classifying the numerous examples by which we propose to demonstrate the frequency and the diversity of spontaneous autosuggestions, we shall in the first instance, apart from all classification, give a few examples which will best enable the reader to understand the working of suggestion and will help him to realize its leading characteristics.

At the outset let us consider the well-known phenomenon of *fascination*, where the attention is so completely captured by an object that the person concerned continually returns to it in spite of himself. In certain neuropathic subjects, fascination displays itself in an aggravated form. But normal persons can grasp what we mean by fascination when they think of the attraction aroused by a luminous point. A still better example is the auditory fascination exercised by a door banging repeatedly during the night, so that we cannot help listening for the recurrence of the sound. We cock our ears as we wait for its coming; and we curse the door that keeps us awake, not so much by the intensity of the noise as by the fact that we are continually on the alert.[1]

What has happened? The first thing is the working

[1] This example and other analogous ones have been ably analyzed by Paul Sourian of Nancy University. Cf. La suggestion dans l'art, Alcan, Paris.

of spontaneous attention. The isolated noise, breaking the silence of the night, naturally attracts the ear. Then, our attention recurring again and again to this noise, we imagine that it is impossible for us to refrain from attending. Next, the idea materializes (here we have suggestion at work), and in fact we are no longer able to withdraw the attention. We have spontaneously suggested our own impotence.

We now make repeated efforts to release the attention from the object which fascinates it, but at each successive effort we feel that our powerlessness becomes more evident. Here is the remarkable point: the effort counteracts itself, turning to the right when it wishes to turn to the left; our effort spontaneously reverses itself in accordance with the idea which actually dominates the mind and which has become a suggestion—the idea of impotence. In a word, the more we wish, the less are we able.

We shall see later that a definite law is here in operation. The characteristics just described as attaching to spontaneous suggestion will stand out far more clearly when they have been evoked as it were to order, by means of reflective or induced suggestion. Coué and other investigators noted these characteristics first of all when they had been artificially evoked, and were subsequently able to recognize them in purely spontaneous suggestions.

From fascination we pass by an easy stage to *obsession*, which is nothing more than a mental fascination, a fascination by images, memories, ideas, from which we cannot free the mind, simply because we think we cannot free it and because this thought becomes a suggestion.

The *fixed idea* is only the ultimate degree of obsession. Moreover, obsession and fascination, which become more overwhelming at every effort made to dispel them, can be dispelled by a reflective autosuggestion or by an induced suggestion. (Let me say parenthetically at this stage that reflective autosuggestion and induced suggestion comprise a form of action totally distinct from voluntary effort.)[1]

Neurasthenia may be considered from the neurological outlook. But mental conditions play a predominant part in this disorder. From the mental point of view it may be said that neurasthenia is an obsession by "black" ideas, melancholy, anguish, a sense of powerlessness, fears more or less well founded. Here, too, effort for deliverance is fatal. To use Coué's simile, the neurasthenic, like a man caught in a quicksand, engulfs himself more hopelessly with every effort he makes to get free. On the other hand, when, through countersuggestion or through any other cause, the autosuggestion of powerlessness disappears from the patient's mind, he immediately finds himself on the high road to recovery.

Furthermore, the psychology of the neurasthenic exhibits certain characteristic features of suggestion which will have to be more fully considered later, for their theoretical and practical consequences are of the first importance. It seems as if the neurasthenic wished to be sad, as if he craved for black ideas. Through the influence of the subconscious he is led unwittingly to seize upon anything which can supply his melancholy with

[1] The reader cannot guard too carefully against confounding voluntary effort with autosuggestion. We shall see that the latter is efficacious precisely in proportion as it is remote from the former.

some shadow of reason. In the newspaper he pounces on a paragraph recording a disaster. In his personal memories, he can recall only the gloomy days. He hunts down painful incidents as a beast hunts its prey. He does this, of course, without wishing to; and he does it all the more when he tries not to. In a word, everything happens as if a single goal were in prospect—to be sorrowful. Everything happens as if the subconscious were employing all possible artifices to attain this goal, were inventing all conceivable means to realize this end. At a later stage we shall analyze yet more striking examples of such teleology.

Our series of preliminary examples must be concluded with an account of *vertigo*. Coué writes on this subject: "Lay upon the ground a plank thirty feet long and nine inches wide. Everyone will be able to walk along this plank without putting a foot to the ground on either side. Now change the conditions of the experiment. Let the plank connect the twin towers of a cathedral, and tell me who will be able to walk for a yard along this narrow pathway. Do you think you will be able to? You could not make a couple of steps without beginning to tremble; and then, despite all your efforts of will, you would inevitably fall."[1]

This well-known phenomenon, a fall due to vertigo, is extremely instructive from the light it throws upon the emotional mechanism of spontaneous suggestion. The perception of the abyss beneath naturally arouses the idea of a possible fall. But often enough we think of a fall without falling. Why, in the present instance,

[1] Coué, De la suggestion et de ses applications. Barbier, Nancy, 1915, pp. 5 and 6.

does the idea of a fall become transformed into a fall? In other words, why does the suggestion realize itself?

Let us examine the matter introspectively. What difference do we find between the case when we think of a fall as we are walking at ease along the ground, and the case when the same thought comes to our minds on the top of a cathedral tower? The difference is that in the latter instance the idea of danger is inseparable from the idea of the fall. We are afraid. When we say this we lay a finger upon the crucial factor of *emotion,* which is the main cause of the majority of spontaneous suggestions. In the case now under consideration, this emotional factor is peculiarly conspicuous; but it is by no means absent from the suggestions previously considered. Obsessions and neurasthenia are sustained by a perpetual accompaniment of emotion, sometimes acute, sometimes massive; and they find an appropriate soil in persons of a highly emotional disposition.

Let us bear in mind, henceforward, this close tie between emotion and spontaneous suggestion. The attention which is the primary cause of spontaneous suggestion is an affective state, and is not purely intellectual. Spontaneous suggestion, like emotion, seizes us without our knowing why. In nothing are we more passive, more carried away despite ourselves. Vertigo is typical of such suggestions; and suggestion itself, in so far as it enters the realm of consciousness, is a sort of vertigo. In so far as it enters the realm of consciousness—this reservation is indispensable; for in many instances the process takes place in the sphere of the subconscious, and the subject is aware of the result alone.

CHAPTER THREE

REPRESENTATIVE SUGGESTIONS

(Images, Judgments, Hallucinations, Hallucination by Compromise and by Transfer)

In view of the practical and pedagogic aim of the present work, it is essential that we should make the reader understand the frequency of spontaneous suggestion. We shall give a great variety of examples, without multiplying them unduly.

These examples must not be presented in disorderly array. A simple classification is the following:

A. Instances belonging to the representative domain (sensations, mental images, dreams, visions, memories, opinions, and all intellectual phenomena);

B. Instances belonging to the affective domain (joy or sorrow, emotions, sentiments, tendencies, passions);

C. Instances belonging to the active or motor domain (actions, volitions, desires, gestures, movements at the periphery or in the interior of the body, functional or organic modifications).

Such is the classification we shall adopt. We shall see that in each of these domains, and in the most varied types of case, spontaneous suggestion is at work. For we say nothing intelligible if we confine ourselves to the abstract principle, "Every idea *tends* to undergo transformation into reality." Such a principle must be considered as nothing more than a convenient means for summarizing a large number of observations. To say that ideas "tend" to realize themselves, implies that in

some instances they realize themselves, whereas in some instances they fail to do so. If the formal phrase is to have a real content, we must show what ideas in actual fact are usually seen undergoing transformation into the corresponding realities. This is our immediate task.

In the representative domain, the fact of suggestion can be expressed by a formula which will at first seem a strange one, namely, *The idea*[1] *of an idea gives birth to this idea.*

As far as the motor domain is concerned, we shall say, *The idea of a movement gives birth to this movement.* This formula is comparatively easy to understand.

In the representative domain, we have to do with a sort of suggestion at second-hand. In this sense the matter is evidently somewhat complex. But from another outlook we are dealing with something simpler than when we enter the motor domain, for is it not more elementary to see an idea undergoing transformation into an idea, than to see an idea undergoing transformation into a movement or into an organic modification? In the former case we have the mind acting on itself. When we move on to study the action of the mind on the body, we feel as if we had passed a stage further, as if we had left the comparatively simple for the comparatively complex.

But what is the idea of an idea? Is it easy to distinguish the state "I think" from the state "I think that I think"? Spinoza[2] believed that the distinction could

[1] The term "idea" is used in the widest sense of "mental representation."

[2] Spinoza, Tractatus de intellectus emendatione. English translation by Hale White, Duckworth, London, 1899, p. 17.

be drawn, and he spoke of the idea of an idea, of the idea of the idea of an idea, and so on, as if they were realities he had seen with his very eyes. In truth this play with abstractions is somewhat artificial. Perhaps it is a mere playing with words; and we must look at the matter more concretely.

The idea of a movement, or let us say the image of a movement, can be clearly distinguished from the movement itself. The same thing can be affirmed of the image of any material object. Whereas the material object is visible to everyone, and forms part of the system of external realities, the image of this object exists only in the mind of the person who thinks that image. You see, just as I see, the house at which I am looking; but you do not see the house of my thought. In contrast with the object, we may say that the image is subjective.

But when the object itself is a mental state, and is therefore subjective, the distinction is no longer possible. Whereas the image of an external object is not an external object, and while being differentiated from the external object by this single characteristic may resemble it in all other respects—the image of a mental state, on the other hand, can be nothing but a mental state. It would seem, then, that we must accept one of two alternatives. Either this state-image has all the characteristics of the state of which it is the image, and in that case the former is not distinguishable from the latter, but is the very state itself. Or else, the former differs from the latter in some respect or other, and then the former is not the image of the latter.

But when we reason thus, we are, as so often happens, duped by our own dilemma. In fact, even if there do not exist, properly speaking, images of mental states,

there do exist equivalents of such images, and we may term them *schemata.*

We wish, for example, to recall a proper name. This name is a mental image. At the moment when we desire to recall it, we doubtless think of this name. Yet it would be incorrect to say that we possess its image, for then we should already possess the name itself. But we remember certain characteristics of the name, the number of syllables, the sound of certain letters, the initial or final consonant, the emotional atmosphere which is associated with it in our mind. We have a *schema* of the name. By the very fact that for a certain time our attention has been fixed upon this schema with the intention of filling in its details, we have started something at work within us. Now, while we are speaking of other things and when we no longer think of the name we require, this work is continued in the subconscious. Suddenly, in the depth of our memory, a call sounds, resembling a telephone bell when the connection we have been seeking is at length established—and the name is remembered.

By this example we may understand what suggestion is in the representative domain.

Amnesia, or loss of memory, may, just like the revival of memories, be the outcome of suggestion. Among hypnotists, it is a classical experiment to suggest to the subject that he has forgotten his own name. But hypnotism merely exhibits in an exaggerated form phenomena which occur in the normal state, and there is no essential difference between heterosuggestion and autosuggestion. There are names which we know as well as we know our own name, and yet they elude us just when we want

them. Often enough, this caprice of memory is very trying to the temper. "How ridiculous!" we say. We swear, we frown, we make desperate efforts to remember —but all in vain.

The failure to remember the item at the precise moment when it is wanted, is due to some specific cause, perhaps to some antecedent suggestion. Whatever the reason, since the name you want was perfectly familiar to you, you are astonished at the disobedience of your memory. The failure to recall what you want, the anomalous working of your brain, positively frightens you. Spontaneously and unconsciously you make an autosuggestion which aggravates the amnesia. And now, the greater the effort you make to remember the name, the more complete becomes the forgetfulness. You have noticed this before in similar instances. You are clearly aware that the harder you try to remember, the more obstinately do you forget. Each successive effort seems, as it were, to trouble more hopelessly the waters of memory, to stir up more mud from the bottom, until at length the whole pool has become turbid. "A moment ago, I had the name on the tip of my tongue, but now I have lost all trace of it." You had a schema in your mind; you tried to fill in the outline, but you feel that this very attempt has effaced the outline; and you feel that the more you try, the more hopeless becomes the obliteration.

But when you have ceased to struggle, when you have left your mind at rest, in the hope that the recollection will turn up later, then, after a while, the name comes back to you.

Moreover, it is not only upon isolated memories that suggestion acts in this way, negatively or positively. Memory as a whole may be similarly affected. In the

majority of amnesias, the part played by suggestion is enormous. We see this when amnesia is rapidly cured by a deliberate countersuggestion.

What, then, is the mechanism of such amnesias?

Let us suppose that two or three times in brief succession you have suffered from one of the above-described lapses of memory, accompanied on each occasion by more or less explicit annoyance. Then the idea takes possession of you that you are losing your memory. In actual fact, now, your memory is adversely affected, simply because you think it, and because your attention has thereby become concentrated upon the idea of amnesia.

In the domain of *judgments* and *opinions,* the rôle of spontaneous suggestion is often disastrous.

At the outset, let us clearly understand the nature of this kind of suggestion. What is the schema of opinion which undergoes transformation into a fixed opinion?

You hear an opinion stated; you are well aware that it is nothing more than an opinion; you have your reserves when you accept it; you intend to look into the matter more closely, to reason about it. At this stage you think the judgments that have been formulated, without believing them in the strict sense of the term. What you have in your mind are not complete judgments, for belief is an integral part of judgment, and here belief is lacking. All that you have is what we may call the "schema" of a judgment, the idea of a judgment (or of that series of judgments which constitutes an opinion).

Time passes, and you no longer think about verification. You even forget the original source of your idea,

But one day you are called upon to decide the question, and you discover that your mind is made up; you hold the very opinion which you heard expressed formerly, although you have never had any proof. The ordinary newspaper reader, the man-in-the-street, is continually circulating these "hearsays," without professing any credence in them. Nevertheless the newspaper reader's opinions are based upon the falsehoods he reads in his favourite paper. He does not realize it, but such is the fact. The grain planted in him when he read, has germinated in the subconscious. He has made up his mind, and he believes that his opinion is established upon reason. The ruling class turns this law skilfully to account when it wishes to drive the human "sheep of Panurge" to the slaughter house.

It is a well-known fact that by repeating tales to themselves and to others, people come to believe what they say, and are duped by their own falsehoods.

Next we pass to consider the rôle of suggestion in the domain of *sensation*. Let me quote some typical examples from Paul Emile Lévy's *l'Education rationelle de la volonté*.[1] Lévy was a pupil of Bernheim, and his book is transitional between the earlier Nancy school and the later. He alludes to an observation made upon himself by Herbert Spencer:

"If I merely think of a slate-pencil squeaking on a slate, my teeth are set on edge just as if I actually heard the sound."

Lévy refers to the familiar experience that merely to

[1] Paul Emile Lévy, The Rational Education of the Will, English translation from the 9th French edition by Florence K. Bright, Rider, London, 1913.

think of itching anywhere suffices to arouse the sensation of itching.

"Everyone knows," he adds, "that if we are expecting a visitor, we are continually hearing the door-bell ring before it really does so."

We may add that while suggestion can thus create wholly imaginary sensations (*hallucinations,* in fact), still more easily and still more frequently does it give rise to partial hallucinations by transforming real sensations to make them correspond to a fixed idea. From among our real sensations, we select those which conform most closely to the image preëxisting in our mind; between the sensation and the image there takes place a compromise, a more or less complete identification. Thus, when we are expecting a visitor, above all when we are awaiting his coming with some anxiety, the crackings of the wood in a piece of furniture or the blows of a hammer in the distance are mistaken by us for the sound of his footsteps on the stair.

In the visual domain, hallucination in the strict sense of the word is rarer than it is in the auditory domain. The difference doubtless depends upon the fact that the image of a noise is not absolutely contradicted by the sensation of a real noise, whereas a vision is often contradicted by the presence of the external objects amid which the vision seems to be situated. These objects then act as "antagonistic reducers," to use the term coined by Taine. I know perfectly well that two objects cannot occupy the same place at the same time, whereas two noises can mingle and interpenetrate. But even though complete hallucination be rare in the visual domain, what I propose to call *hallucination by compromise* is of fre-

quent occurrence. Phantoms make their appearance above all in the night, when the outlines of objects are comparatively hazy, so that their forms are more elastic to the imagination. A pillar, the white wraith of a fountain, the bright space between two trees—such things constitute the material substratum of a phantom, owing to the resemblance between their appearance and that of the imagined winding-sheet.

This phenomenon will be more readily understood when we contemplate its exaggeration in the state of hypnosis. In this condition, complete hallucination is by no means rare, but it is interesting to note that hallucination by compromise is often preferred by the subject. The imagination, instead of inventing out of whole cloth, makes use of elements borrowed from real sensations. This is an economy, an application of the law of least effort.

In this connection, let me record an experiment of my own.

I had induced hypnosis in a boy of twelve, who was extremely fond of chocolate éclairs. Giving him a plate to hold, I suggested that he should see in it a chocolate éclair. Now, on the plate was a reproduction of Millet's celebrated picture *The Gleaners,* in which there are three female figures, two bending forwards and one upright. After a second or two, the boy said in high glee: "But there are three chocolate éclairs, and two of them have an odd shape, for they are bent in the middle." This was a well-marked instance of hallucination by compromise.

The same type of hallucination, in a somewhat attenuated form, is commonly manifested in the work of great poets. Real objects are modified in form by the internal

visions they resemble, so that the real objects seem to be materializations of the visions. In Victor Hugo's writings, such direct metaphor is exceedingly common. Let me quote one example from among many.

The poet has just encountered a flock of sheep with a girl herding them. His thoughts have agreeably loitered in retrospective contemplation of this sight. Now his path leads him to the seashore, and here the surroundings seem modified to fit his reverie. Anyone who wishes fully to understand what passes in the poet's mind should (like the present writer) retrace Hugo's footsteps and read "Pasteurs et troupeaux"[1] in its original setting. The waves are breaking on Grouville beach. It is eventide, and the full moon is about to rise upon the sea. The outlines of the landscape are ill-defined, and in the hypnotic atmosphere it is easy for the imagination to transfigure them. Leftward, the ruins of the castle of Montorgueil thrust like a human head above the promontory which juts southward into the sea at the northern extremity of the bay. The vision of the flock has lingered in the poet's mind.

Down there before me the pensive old watchman,
Guarding the seafoam, the tides, the seaweed, the reef,
And the surges beating ceaselessly upon the shore,
The shepherd headland, wearing a cap of cloud-drift,
Leaning on elbows, dreams to the murmur of all the infinites,
And contemplates the triumphant rising of the moon
Amid the wraithlike forms of glorious cloud,
While the darkness trembles, and the biting squall,
Scatters to the winds, with its fierce breath,
The wool of the sinister ocean sheep.

Elsewhere the poet, burning with indignation at the

[1] Les Contemplations.

memory of an execution which continues to haunt his thoughts, seeing the moon rise red and sanguine, writes: "I saw this severed head roll on the ground."[1] But the same moon, one evening when he is engaged in religious meditation, becomes "a huge consecrated wafer." Another night, when he is in a similar mood, he refers to the stars as "fragments of white-hot charcoal scattered from the censer of the infinite"; again, in a burst of lyrical enthusiasm, he speaks of the stars as "sparks which flash beneath the hoofs of Pegasus"; whilst on a night of pessimism the constellations are "the marks of the prison-house stamped on the world's shoulder." This enumeration could readily be prolonged.

Hallucination by compromise is a good example of the law of teleology which dominates suggestion, a law to which reference has already been made in connection with neurasthenia. The internal image which wishes to realize itself in the form of sensation is opposed by antagonistic reducers which are real sensations; but it transforms these obstacles into aids; subconsciously, it chooses from among them those which it can best turn to account, those which can serve it as material; and upon this material it stamps its own impress. This is obvious in Hugo's "ocean sheep." In the case of the "white-hot charcoal from the censer," and in that of the "consecrated wafer," the process is somewhat different. We cannot say that the image of the censer, or that of the host, existed in the poet's mind in a conscious form; what he was conscious of was an affective state, the state of religious contemplation. The image of the host, the image of the censer, etc., were associated with this state in the subconscious; they were "preconscious," were,

[1] Les Châtiments.

that is to say, quite ready to rise to the surface; the sight of a real object called them up by resemblance. The case of the "severed head" was of a type intermediate between those just analyzed. The poet's mind was mastered by an affective state, wherein rage and pity were combined. But with this state there were intermingled images which passed one after another through consciousness: the guillotine, the condemned man, his aspect, the waiting crowd, and so on. Among these images was that of the severed head. It had flashed through consciousness, several times perhaps; and when not actually present to consciousness it had remained in the preconscious, intimately associated with the dominant affective state.

We lay stress upon these examples, for they supply an answer to an obvious objection, and they are instances of the working of the remarkable law of *transference.*

Suggestion is an idea which, subconsciously, transforms itself into the corresponding reality. But in that case, we shall be told, a hallucination could only be a suggestion when the subject has been expecting it, when he has already had the mental image whereof the hallucination gives him a quasi-material sensation. Nay, more, his mind must have been positively obsessed, his attention must have been monopolized by this mental image. Now, the majority of persons who suffer from hallucinations insist that their "voices" or their "visions" take them entirely unawares, come unexpectedly out of the void, startling their imagination and often producing actual dismay. Here, it would seem at first sight, there can be no question of suggestion, seeing that the first of the three phases, the preliminary idea of the thing realized, is lacking.

In exceptional instances, this objection may be valid, or must be admitted as a logical possibility; but far more often it can be refuted by careful observation. The examples given above furnish the key for the refutation of the criticism.

In the case of the severed head, and still more in those of the host and of the censer, it was not the mental image of these things which engrossed the attention at the outset; the attention was already engrossed, as it is in the origination of every suggestion. The obsession was there, but it was obsession by an affective state, not by an image. Nevertheless, in the poet's subconsciousness, the image was closely associated with this affective state. (In early youth, his only experience of religious contemplation had been gained in Catholic churches, and in connection with the host and with censers.) By the chance play of objective sensations, these slumbering images, so intimately related to his actual state of mind, were reawakened. Thereafter, everything happened as if the obsession had been transferred from the affective state to the image so closely associated with that state, the image which symbolized that state, so that by spontaneous suggestion the image was then realized in hallucinatory form.

This transference is a further manifestation of the teleology of the subconscious. Every state which engrosses the mind, tends in one way or another to secure external expression, for it is a concentrated energy which wishes to diffuse itself. Now for Victor Hugo, hallucination by compromise, which in him is the source of symbolical poetry, is the normal method of discharge. But an affective state cannot thus be externalized. We

cannot visualize religious contemplation; we cannot visualize wrath. The obsession, therefore, is transferred. A visible object, a symbol (the censer, the severed head), is substituted for the unduly abstract emotional object, and the suggestion then runs its course.

These examples of hallucination by compromise will enable the reader to gain a clear understanding of the process of transference, which appears to be the general law governing all hallucinations of such a character. A neuropath for whom all the stones in the road become pustules, for whom every runnel of water is a loathsome issue of some morbid humour, may not be directly obsessed by such images; but he is manifestly obsessed by ideas, by fears, of disease and of decomposition. These ideas and fears are too abstract to be externalized, and they are therefore replaced by the concrete visions which are associated with them.

The law of transference is likewise in operation in the origination of certain complete hallucinations. In the preceding instances, the immediate cause of the transference was to be found in the chance working of external circumstances, of real sensations. But in other instances the entire process is internal. Transference has been carefully studied by the psychoanalysts, and they have shown that it may result from a number of subconscious influences, and above all from the working of repression.[1] The analysis of a case of hallucination reported by Auguste Lemaître [2] will enable us to understand the genesis of hallucination by repression. We see in it an example

[1] Cf. Régis and Hesnard, Psychoanalyse des névroses et des psychoses, Alcan, Paris.

[2] "Archives de Psychologie," July, 1916, Kundig, Geneva.

of suggestion in which both the first phase and the second phase remain in the sphere of the subconscious. But the process is none the less complete. Here is the history of the case:

"Amédée was a boy of fifteen. During the Easter holidays he was in a mountain region, and after he had been there two weeks he became suddenly subject to hallucinations. He was an intelligent lad with more inclination for study than for out-of-door amusements; but for health reasons he somewhat reluctantly devoted himself to these latter for an hour or so daily. His environment was one of kindliness, but he was far from sharing the luxurious tastes of his family. In fact, he felt himself out of place in these surroundings. The commonplaceness of everyday life, even when richly gilded, had for a year past, since he had begun to think, filled him with aversion. He had grown more and more depressed. During the above-mentioned visit to the mountains, when his parents said to him, 'You'd much better go out tobogganing, instead of frowsting over your books!' this remonstrance caused him a violent internal shock. His own words to me were: 'They used to treat me as if I were an imbecile; they said I looked like a lunatic or an embryo philosopher. And all because, during the evenings in the hotel, I did not want to dance or to play the fool with the others.'

"In Amédée's family there was no history of neuropathic taint, except that one of his uncles had been a sleep-walker. The patient himself, when about twelve years of age, had on two or three occasions walked in his sleep.

"The hallucinations, as I have said, began towards the close of his stay in the mountain resort. Both the

visual and the auditory hallucinations had a characteristic which caused him great astonishment; they were *fragmented.*

"Here is his own account of them: 'Often, while at work or while talking with someone, I suddenly cease to see the persons with whom I am conversing, and the other objects around me; I am plunged into a dream or vision. Frequently I see a woman who is tall and elegantly formed, dressed in white, seated at a table and leaning on one elbow. On the table there is a lighted lamp. She is looking out of the window, and is patting a dog, which has no hair and no legs. Of this woman I see only the head and arms and the upper part of the trunk, and, lower down, the crossed legs.'

"As a rule, the hallucination affects him in the evening. On May 8th, at 6:30 P. M., 'I felt a hand stroking my cheek, and it seemed to me that I must be going mad.' On May 13th, at about 7:30 P. M., 'I saw a woman who had no arms, and who was turning her head from side to side.'"

The history refers to other hallucinations which we need not describe, for the report is not sufficiently detailed to enable us to make a satisfactory analysis. All these hallucinations were fragmented; from the utterance of the "voices" certain words were missing; moreover, the author lays stress on the hours at which the phenomena occurred (4:30, 6:30, 7:30)—the very times were not integers. His inference is that all these hallucinations related to the sentiment of incompleteness with which the lad was affected. They symbolized this feeling, which was transferred to the symbolical images.

But the few hallucinations which we have selected from among all those recorded in the clinical history,

enable us to undertake a more exhaustive study, employing the psychoanalytic method.

The patient's age and the nature of the visions combine to show that their cause was deeply rooted in the domain of sex. Moreover, in the boy's detestation of luxurious living, of dancing, etc., psychoanalysis discloses to us the results of a repression of sexual matters.[1] He refuses to admit the existence within him of certain desires. The very images habitually associated with these desires are repressed by the endopsychic censor; and it is to these associated images that the affective obsession is transferred. Note more particularly that, in the visions, the more significant portions of the body are systematically suppressed. All this work of substitution has been effected in the subconscious. The upper consciousness is unaware of what has been going on in the depths; it is astonished, and sometimes alarmed, at the results of the process.

Hallucinatory suggestion (except hallucination by compromise) is rare in adults. But in children it is fairly common.

I can myself recall having seen, in childhood, a vision of bells flying through the air, ringing as they flew. It was on the Saturday before Easter, and these bells were bringing from Rome the greatly desired Easter eggs.

George Sand and Carl Spitteler have recorded memories of childhood displaying analogous phenomena, more or less strongly marked. It is probable that as we become more intimately acquainted with the psychic life

[1] Cf. Baudouin, Psychoanalyse, Observation No. 2. "Archives de Psychologie," 1916, Kundig, Geneva.

of children, we shall discover that spontaneous suggestions of this kind are far from rare.

Finally, an idea may not only induce sensation; it may also inhibit sensation. Thus, a person suffering from a severe cold, being no longer able to perceive a faint odour, will imagine that the sense of smell has been totally lost, and will in actual fact be unable to smell anything.

CHAPTER FOUR

AFFECTIVE SUGGESTIONS

(Sensations, Emotions, the Peripheral Theory of Emotion)

As we pass from the representative sphere to the affective sphere, sensations provide us with a natural stepping-stone. As a general rule, sensations are simultaneously affective and representative. Certain sensations of heat and cold, and to a still greater degree certain visceral sensations, are often attended with pain which may preponderate very markedly over the representative element.

The idea of a sensation of pleasure or pain, the idea of a feeling, tends to become this pleasure, this pain, or this feeling.

Here, again, we have to point out that such an idea is rather a schema than an image properly so called. When we think of a pain, we feel (unless our representation be purely verbal) a sort of reduced copy of the pain, as if we had only just experienced it, and as if a faint trace of it, a vague emotional echo of it, still remained. The vividness of this echo varies in different persons. There are some who, directly they hear any physical suffering spoken of, promptly display upon their faces the customary signs of pain. The forehead becomes furrowed, the corners of the mouth are spasmodically raised. This

implies that one who thinks of a pain, begins to feel it, has already a rough sketch of it in his sensorium. If, now, the attention becomes unduly concentrated upon this sketch, this schema, or if the attention returns to it too often, suggestion is unleashed. The same considerations apply to every kind of affective state.

As far as visceral sensations are concerned, Herbert Parkyn, in his excellent manual of autosuggestion,[1] records the following incident. It has its amusing side, so that it sticks in the memory.

"A New York visitor in Chicago looks at his watch, which is set an hour ahead of Chicago time, and tells a Chicago friend that it is twelve o'clock. The Chicago friend, not considering the difference in time between Chicago and New York, tells the New Yorker that he is hungry and that he must go to lunch. Twelve o'clock is the Chicago man's regular lunch hour, and the mere mention of twelve o'clock is sufficient to arouse his appetite" (pp. 11–12).

Suggestion may also act negatively. Bernheim maintains that in fasting men the sensation of hunger is neutralized by an idea.

Phenomena of this character occur in connection with all kinds of sensation.

Parkyn reminds us that a man, after touching some article of clothing, may be told that it has been worn by someone suffering from skin disease. The subject thereupon has itching sensations all over the body, and fancies he has caught the disease. Again, medical students who study the symptoms of various diseases frequently exhibit these symptoms and imagine themselves to suffer from the diseases in question. Facts of this order are

[1] Herbert Parkyn, Auto-Suggestion, Fowler, London, 1916.

quite familiar. The pamphlets, leaflets, and advertisements issued by the vendors of patent medicines vaunting specifics for all and sundry diseases whose symptoms are described with a wealth of detail, are responsible for an enormous amount of suffering.

Paul Emile Lévy lays great stress upon negative suggestions, those which inhibit sensation; and he is right, for the deliberate use of suggestions of this character is most valuable in promoting the relief of various painful symptoms. Here is an instance given by this author:[1]

"The following fact came under my observation: A patient complained of a severe pain, the sequel of a violent blow on the chest. His temperature was taken with a clinical thermometer, and when the instrument was withdrawn he said: 'That has eased me greatly!'— Other authors have recorded precisely similar occurrences. Many martyrs have endured torture with a serenity of spirit which, they assure us, they were able to maintain without the smallest difficulty. Their attention was monopolized by the beatific visions with which their ecstatic minds were filled, so that they were unaware of physical suffering."

The painful sensation of cold (which is simultaneously representative and affective) may be to a large extent neutralized by suggestion. On the other hand, it may be greatly intensified by the same cause.

A resident in Nancy, one who has since learned to make good use of autosuggestion, reported to me the following incident:

"When I got out of bed one morning the window was wide open and the sun was shining brightly. The mere sight of the sun made me feel cheerful and warm. I put

[1] Op. cit.

on very light clothing and went about my business with bare arms, and nevertheless felt a great deal warmer than I had felt during the last few days. Then I went to the window and saw that it had been snowing. A glance at the thermometer convinced me that the winter had set in. Immediately I felt cold; my teeth chattered and I began to shiver."

Thus the sun had induced the idea of warmth, and had even sufficed to arouse the sensation of warmth, or at least to neutralize the sensation of cold. But the sight of the snow in conjunction with the reading of the thermometer aroused the idea of cold, and the sensation of cold promptly ensued.

Everyone knows, though not everyone fully realizes, how the sight of a fire which has just been lighted, and which has not yet begun to throw out any heat, will make us feel warm, thanks to the idea of heat which it arouses by a natural association. In a child, the memory of having suffered greatly from cold one day in the previous winter will arouse a dread of winter, and all the more if, in answer to the child's question, "What is winter?" we have foolishly answered, "Winter is the season when we suffer from cold." Such a child will be "a chilly mortal" throughout life, or at least until he has realized that he has been a victim of suggestion. It may be that some countersuggestion, like the amulet or talisman in a fairy tale, will deliver him from his thraldom. In like manner, one who has never before been sensitive to cold, will become so during a fever and will remain so after the fever, when the exciting cause of the chilliness has vanished. Similar factors are at work in the case of persons who declare they cannot endure heat.

The sensation of weight and the fatigue that accom-

panies it, and also the fatigue which comes from walking or from any other form of exercise, are the sport of unceasing suggestions. This is particularly noticeable in the case of children. If, when you are out walking with a child, you are so heedless as to say you are tired, it is ten to one that the child will say "So am I," and will immediately begin to flag and to fall behind. But in this respect we grown-ups resemble children much more than we are apt to fancy. A peasant, carrying a basket on his back, will stoop under its weight although he has unwittingly dropped the contents on the road. When, during a walk of two or three miles, we are dull and imagine ourselves to have traversed double the distance, we are correspondingly fatigued. But the reverse is equally true, and this latter fact is susceptible of the most valuable practical applications.

As far as concerns physical pain in general, suggestion will sometimes intensify it, and will sometimes act as an anæsthetic. Coué gives the following familiar instance:

"Consider, for example, a little child. He has pinched his finger or scratched his hand. Instinctively he begins to cry, for the pain is more or less sharp. His mother runs to him, blows on his hand, rubs the sore place gently, tells him it is all over now and that it doesn't hurt any more. Thereupon the child stops crying and begins to smile. Wherefore? The child hears his mother say, 'It doesn't hurt now.' His unconscious believes it. He imagines that there is no more pain, and actually he ceases to feel the pain.

"But if the mother, greatly alarmed, exclaims: 'Poor little darling, how you have hurt yourself!' the child

redoubles his outcries. In this case, likewise, the child's unconscious believes the mother's words. The idea that the suffering is great, increases the suffering."

The reader may object that this example, and also that of the child which gets tired on hearing someone else complain of being tired, have nothing to do with the subject under discussion, seeing that they are hetero-suggestions. But comparison with the adjoining instances will show that the parent's words act only by way of the child's imagination, and become suggestions only after they have been accepted by the child.

Besides, in this case as well, we may say that we grown-ups are more childlike than we suppose. We shall learn that suggestion consciously utilized by the adult may become a potent anæsthetic. But so long as we remain ignorant of this, our trouble is that we are just as credulous as any child, with the difference that we are credulous in a bad sense while the child is credulous in a good sense. He believes that his mother's blowing on the sore place eases the pain; and inasmuch as he believes it, it is true. For our part, we believe that we can only get relief by having recourse to a pharmaceutical arsenal; and as long as we believe this, as long as we remain ignorant of the power possessed by the brain over the rest of the organism, so long does our belief remain true, so long are we unable to do without the arsenal. But, per se, our negative superstition is a trifle more fallacious than the positive superstition of the child.

It suffices for us to imagine ourselves poisoned by fungi; thereupon we are seized with violent colic. In this and in similar cases, we manifestly encounter two

important factors of suggestion: *emotion* (fear, in the instance just given) and *attention*. The latter is sustained to the pitch of obsession, and is kept up by emotion.

But *emotion* (the acute affective state) is not merely a factor of suggestion, not merely an auxiliary in the production of suggestions. It may in its turn be the object of a suggestion, and the idea of an emotion frequently gives rise to this emotion.

Nothing predisposes to fear like the conviction that we shall be afraid, and, above all, the conviction that we shall be afraid in certain specific conditions. Nothing predisposes to anger like the memory of a previous occasion when our anger passed beyond our control, and the more or less conscious realization that the same thing will inevitably happen should the same conditions recur.

But the idea, the schema, of an emotion is not necessarily a purely internal state. In contradistinction to what occurs in the case of movements, which are externalized phenomena although their image is purely mental, it frequently happens that emotion, an internal state, has external objects for its image, its schema. I refer to the physical signs which are the habitual accompaniments of emotion, which are its expression, and which arouse it. Those who see in another the signs of fear; those who discern in their companions pallor of the face, a terror-stricken look in the eyes, a trembling of the limbs; those who hear others stammer with fright, or who in a crowd hear the panic-stricken cry, "All's lost, every man for himself!"—are not slow to become affected with the highly contagious emotion of fear.

Thus the collective fear which we term panic rapidly spreads through an assembly, an army, a country.

According to what is known as the *peripheral theory of the emotions,* which derives from Lange and William James, it is an error to believe that emotion secures expression through physical signs. These psychologists hold, on the contrary, that the physical signs are the actual cause of the emotion. We ought not, they contend, to say: "We weep because we are sad; we tremble because we are afraid; we clench our fists because we are angry." We ought to say: "We are sad because we weep; we are afraid because we tremble"; and so on. Were this theory sound, the foregoing suggestion would have to be classed, not as an emotional suggestion, but as a motor suggestion. The sight of the movements which express fear in others would have suggested analogous movements to the subject; and these movements, by a natural sequence, would then have aroused in him the emotion which is invariably associated with such movements.

Against this interpretation, it may be objected that as a rule the motor suggestions induced by the sight of others' movements do not operate with the requisite degree of intensity. If we imitate the movements of persons who are afraid, why do not we likewise imitate the contortions of acrobats, persons whom we usually watch with close attention? Does not the difference show clearly that in the production of fear there is some other influence at work? It is true that those who accept the views of William James might reply as follows: The sight of the movements expressive of fear suggests at the outset the same movements to us, in an infinitesimal manner, as in the case of all movements which we

witness. But in this case the beginnings of movement at the periphery involve the beginnings of the emotion of fear. This emotion, like all others, makes suggestion more active, and redoubles the intensity of the movements; these, in turn, increase the intensity of the emotion; and so on. It is as if we had to do with a self-starting, self-exciting dynamo; the current and the magnification mutually increase one another, and both speedily attain to a maximum.

There is some force in the answer. Moreover, it is true that there are other facts, still within the field of suggestion, which seem to speak in favour of James's theory. For example, the most potent method of overcoming fear by induced suggestion would appear to be for the suggester to direct his attention, not to the fear itself, but to the accompanying movements.

A boy of twelve had from earliest childhood evinced a positive phobia of toads. Whenever he caught sight of one, his face grew pale, his back became arched, and he made convulsive movements with the forearms. This phobia had originated in imitation of his mother, who had similarly derived it imitatively from her mother. Ascending through the generations, the symptoms were more violent. The grandmother had a severe nervous paroxysm at the sight of a toad, falling convulsed to the ground. In her case, too, the trouble came by imitation. Her mother, in a deathbed delirium, witnessed by the daughter, had been affected with the hallucination that toads were crawling all over her body. In treating the boy, I dealt with the motor symptoms, saying, "You will no longer arch your back at sight of a toad," etc. After three sittings at which these suggestions were made in the waking state, the phobia had disappeared.

It seemed as if, by stopping the movements expressive of fear, I had actually dealt with the cause of the fear.

But the opponents of the peripheral theory will not admit defeat. They can raise two valid objections:

1. We know that suggestion acts through teleology; we know that when the end is proposed, the subconscious finds means for the attainment of this end, discovers methods for its realization. The emotion, therefore, can perfectly well be the cause of the movements.[1]

2. The case given as an example shows that the phobia was the outcome of imitation, was derived from a suggestion aroused by the sight of the movements expressive of fear. In an emotion suggested in this manner, it is quite possible that the movements in question play a preponderant part; but it does not follow that all emotions are explicable in the same way.

To sum up, the phenomena of suggestion have not, as yet, enabled us to solve the problem definitively. But we shall clear the issues if we juxtapose the problem of the *emotions* with the problem of *affective sensations*, which has already been studied.

Emotion, which in greater or less degree always underlies joy or sorrow, is obviously a phenomenon belonging to the same psychological category as affective sensation—for instance, the painful sensation of weight, of fatigue, or of cold.

Now when we study affective sensations, we perceive that their motor accompaniments play a secondary part, and cannot be considered as their cause. On the other

[1] The reader is referred to the example given at the beginning of Chapter VIII, Part I (the law of subconscious teleology), where an affective state (astonishment) is used as a means for realizing a motor suggestion (the crossing of the arms).

hand, these sensations can be suggested, just as emotions can be suggested, by external things which symbolize them, by external things which are not always movements. To shrivel up at the thought of cold, to utter a guttural "grrr!" are excellent ways of making oneself feel chilly when it is really quite warm. The practice of muffling oneself up is a no less efficacious means, for, even before we hamper the circulation by this practice, we thus arouse the idea that the cold is a terrible enemy, is a sort of polar bear from which we must protect ourselves by elaborate special equipment. Winter, rigged out and solemnized in this manner, exercises upon our minds a suggestion analogous to that which Pascal discerned in the ceremonial robes of the doctors and of all the high dignitaries of his day. Nevertheless, the sensation of cold is not *caused* by these trappings, nor yet by our shrinking from the cold and by the chattering of our teeth. The thermic sense is modelled after the same manner as the other senses. We should be wrong to imagine that the sensations of heat and cold differ fundamentally in the way they function from the sensations of sight and hearing, which latter are obviously not the outcome of any bodily movements. But it is perfectly true that the movements we make when we shrivel up or curl up [1] from cold, the movements we make when our teeth chatter, being intimately associated with the sensation of cold, prolonging and expressing that sensation, arouse it and tend to suggest it, or to amplify it by suggestion if it already exists.

[1] This gesture, an ancestral heritage, appears to be the vestige of an effective means of defence against cold. But in the conditions under which we now live, it is unmeaning, and serves only to suggest the sensation of cold.

By analogy we may infer with a high degree of probability that the same is true of the emotions, that it is true of fear for example. I cannot think that fear, in its essential nature, is caused by the motor disturbances which are its accompaniments.[1] But as soon as these disturbances begin, they suggest to us the fear they symbolize. This gives a plausible foundation for the peripheral theory, and there can be no doubt that a large part of the emotion we feel is caused by suggestions of this character. Herein we discover additional proof of the important rôle of suggestion in such cases.

This rôle need not surprise us. As we have repeatedly had occasion to recognize, emotion favours and powerfully reinforces suggestion. Now, when the object of suggestion is emotion itself, this emotion which we do not begin to feel until we think about it, is nevertheless present from the outset in an attenuated form, and endures throughout the motor process. It never ceases to render the motor process more active. Suggestion, here, is in a peculiarly favourable position.

What we have just said concerning the rôle of motor expression in the suggestion of such emotions as fear and anger, and in the suggestion of such a sensation as cold, enables us at this stage to formulate a practical rule. In the case of fear or anger, we should repress the movements characteristic of these emotions, and should cultivate physical impassibility. In the case of cold, we should adopt an upright and offensive attitude, instead of a curled up and defensive or shivery attitude; we should do this directly we begin to feel, and even before we begin to feel, cold. In view of the power of sug-

[1] The emotion remains peripheral, in this sense, that it usually originates in external sensations.

gestion in this field, such a veto imposed at the outset upon an impending suggestion is of greater importance than anyone could imagine who had not made personal trial of the method.[1]

[1] Concerning the suggestion of emotions by their motor expression, Pierre Bovet writes as follows (L'instinct combatif Délachaux and Niestlé, Neuchâtel, 1917): "Emotion spreads by inducing the imitative reproduction of the gestures which express emotion. This enables us to understand why emotion spreads more readily in proportion as it is more violent, and why a crowd so readily becomes affected with a paroxysm of emotion."

CHAPTER FIVE

AFFECTIVE SUGGESTIONS
(*continued*)

(*Sentiments, Tendencies, Passions*)

SUGGESTION also plays a great part in the life of *sentiment*. By its nature, sentiment is akin to emotion, being differentiated therefrom by its less abrupt and comparatively stable character. Sentiment is more inward than emotion; physical changes are less in evidence; consequently, it is easier to feign a sentiment like love or hate, than to feign an emotion like anger.

A sentiment, like an image, is characteristically internal. As in the case of the image, therefore, it is peculiarly true that the idea of a sentiment is already the sentiment. This applies even more fully to sentiments than to images (at any rate to visual and auditory images, which are the chief images). The mental image of an object seen or of a word heard is, in fact, susceptible of analysis into parts. Thus the idea of an image may be conceived as consisting of certain salient parts of the image, whereas other parts are wanting; this is what we have termed a "schema." But the idea of fragmentation must not be taken too literally. The simplification which leads to the formation of the schema resembles the simplification that occurs in the view of an object when we see it from a greater distance. It is as if, as we move away, the object loses one detail after another.[1] The idea or schema of an image differs from

[1] Bergson's analysis has shown how artificial is our conception of mental phenomena as fragmented, as atomized.

that image as the object seen at a distance differs from the same object viewed close at hand. Many of the details are, as it were, stumped; only in the case of a few salient details are the outlines still discernible. Thus, in the case of a person's name, we referred to the sound of certain consonants, to the number of the letters, etc., as elements making up the schema. The schema differs from the complete image in that certain of the constituent parts of the image are lacking in the schema.

In the case of the sentiment, there is a difference. The sentiment is synthetic; if we explain it, if we analyze it, it loses thereby its primary essence. "If we reason about love, we destroy love," writes Tolstoi. Speaking generally, the application to sentiment of intellectual processes (which are by nature analytical) is destructive to sentiment. For sentiment is non-analytical; it is not made up of parts; it is an indivisible whole, and you have to take it or leave it. It follows that the idea of a sentiment cannot be the partial revival of the sentiment. The difference between the sentiment and the idea of the sentiment cannot be a difference of kind; it can merely be a difference of degree, of intensity.

This implies that when we think of a sentiment we do, in the strict sense of the term, begin to feel it.

In these conditions, suggestion is exceptionally easy. When the idea of a sentiment lingers in the mind, when our attention continually recurs to it, we may look upon our idea as a command, as a prophecy; and it is probable that, in the end, the sentiment will manifest itself in full vigour. The fact that we call it up, indicates that it is already there. We are reminded of the profound saying of Pascal: "You would not have sought me had you not already found me."

Nevertheless, it is by insensible degrees that we pass from emotion to sentiment. Despite its inwardness, a sentiment is accompanied by physical disturbance, which is less conspicuous than that which accompanies emotion, but is no less real. This disturbance, likewise, is externalized in gesture and in speech.

It is a commonplace to say that to give expression to a sentiment, above all to a painful sentiment, is a relief. The term "expression" here partially regains its literal sense. When we squeeze a wet sponge, we express water from it, we get rid of the excess. Some go so far as to declare that sentiment can destroy itself through securing expression. Goethe tells us that by writing *Werther* he freed himself from a suicidal impulse. In truth, however, there is something more at work here than the mere fact of expression. There is an imaginary gratification of desire, analogous to the satisfaction that our repressed impulses secure in dreams. (The writer of *Werther,* affected with a suicidal impulse, killed himself in imagination.) When the expression of a sentiment gives relief, a similar mechanism may often be at work.

I have known persons who, when morally wounded by another, immediately responded by invective and insult (sometimes in all seriousness, and sometimes in a tone of assumed pleasantry, but through which anger breathed). They declared that did they fail to give vent to their feelings, they would bottle something up, and they did not wish to retain any rancour towards one dear to them. Here, again, the rancour has been discharged through finding indirect satisfaction, through securing a derivative.

It may also be contended that the expression of a moral smart gives relief, not per se, but through the

satisfaction it gives us to gain a hearing, and to find sympathizers.

Possibly, again, when a sentiment reaches paroxysmal intensity, its expression is a discharge of tension, as when Ariadne bewails Theseus and proclaims her woes to the winds and the waves, or as when Victor Hugo declaims to the waves on the Jersey coast his anger towards and his hatred for the man of the Second of December.[1]

In these cases too, however, I believe that what gives relief is not the mere fact of expression, but the discharge, the indirect satisfaction. We address things and animals while personifying them, imagining for the moment that they can understand us. Except for the poetic terminology, Ariadne does not differ essentially from the old maid who confides in her cat, thus gratifying her need for sympathy. Victor Hugo sublimates his rancour and his desire for vengeance. He writes *Les Châtiments*, since he cannot, and indeed would not, chastise in reality. Ariadne, having lost the object of her love, substitutes the sea for this object. In like manner Hugo substitutes the sea for the object of his hatred:

Besides, gloomy ocean, I hate thee.[2]

In a word, it would seem that the fact of expression does not in itself constitute the discharge, but that it

[1] 1851, the coup d'état of Louis Napoleon—TRANSLATORS' NOTE.

[2] A classical instance of transferred emotion. The sea is associated in his mind with the prison-ships on which those condemned after the coup d'état were transported to Cayenne. The sea has become the accomplice, the "handmaiden," of the detested ruler, and is therefore substituted for him as the object of hate.

acts in virtue of some external cause which is intermingled with the expression (sympathy, derivation).

On the other hand, the expression of a sentiment, like the expression of an emotion, seems to be by its very nature eminently suggestive, not merely for others, but for the subject himself. According to Pascal, one who takes holy water and makes the sign of the cross will not fail in the end to become a believer.

We shall discuss later the rôle of art, but we may enquire here whether it be not the function of art to suggest sentiments by giving them expression. Furthermore (conversely with what happened in the case of the author of *Werther*), it is obvious that in many instances the artist intensifies his own sentiment by the mere fact of expressing it. A poem is begun in a comparatively indifferent emotional state, but by the time he reaches the third or fourth stanza the writer's eyes are moist. Sometimes the opening stanzas will merely have served to suggest a livelier sentiment to the author, and in the final revision of the poem they will be suppressed because they seem weak and spiritless in comparison with those that follow—although they paved the way for these. The musician's "prelude," the painter's "study," have a similar preparatory rôle. Sometimes, when the work of expression is finished, it comes to exercise the strongest suggestive power on the writer.

> There are verses of mine which I wrote without weeping,
> Yet now, on rereading, they move me to tears.

We are told that Nietzsche, rereading his own *Zarathustra,* was so strongly moved that he was unable to finish the book.

The domain of art furnishes us with other examples

of spontaneous suggestion. I refer to the suggestions which control public appreciation, whether favourable or unfavourable. People are guided by the critics, by fashion, by the comments of the catalogue they glance at in front of every picture to learn what they ought to feel about it. Quite common is a horror of anything that is new in style, a dislike for any work that has not been consecrated as a masterpiece. But when this consecration has taken place, people will admire with a fervour equal to that with which they have previously despised. In others we observe a tendency to rush after every novelty, a fondness for the ultrafuturist. Thus some find a work beautiful and touching in proportion as it is in conformity with the established canons and is like everything else, whilst others admire a work and are moved by it in proportion as it is unlike everything else. And, apart from a few humbugs, the public is in either case perfectly sincere.

There have been epidemics of despair, epidemics of suicide. But another thing which shows clearly the extent to which sentiments are spread by suggestion, and the way in which they affect human collectivities, is the existence of a typical sentimentalism in each epoch. When a sentiment is genuinely original, when it is the true reflection of the individual's personal reactions, it naturally differs in persons of different temperaments. On the other hand, to-day no less than in former times, similar varieties of temperament must exist, and these must react in similar ways. But human beings living in intimate association react in an almost uniform manner, and the general manifestations of sentiment differ from age to age. Romanticism was a collective crisis; it dominated sentiment for many years, and then gave

place to a new type of feeling. Such phenomena are not wholly explicable by historical happenings, or by changes in social conditions. We must rather say that the sensibility of one person, or of a few, arouses widespread suggestive imitation; and it has often been pointed out that the whole romanticist movement existed by anticipation in Rousseau. In like manner the sensibility of our own epoch, in certain circles at least, is the outcome of strong doses of Nietzschean suggestion—more or less distorted. We do not allege that everything can be explained by suggestion. We merely wish to reveal its presence and to demonstrate its power. Why is one model chosen in preference to another? The reasons for such a preference are doubtless complex; but as far as the present argument is concerned the important point is that people do choose a model, and imitate that model without fully realizing that they are doing so. As Bernheim phrased it: "Suggestion is not everything; but in everything there is a suggestive element."

From sentiments we naturally pass to *tendencies* which, under the form of tastes, inclinations, and passions, constitute, as Ribot has shown, the mainspring of the affective life, and form the ultimate foundation of the sentiments themselves.

There are a few primordial tendencies, and the function of the chief of these is to favour the preservation of the individual or the species. Suggestion plays its part, sometimes in inhibiting these primitive tendencies, but more often in accentuating them; it also promotes the development of secondary tendencies grafted upon the primary ones.

The instinct of self-preservation is displayed in a

number of tendencies, the chief of which is the nutritive impulse. We have seen that this impulse is inhibited in fasting men. But sometimes it is accentuated by suggestion. A person was told one day that his appetite was immoderate, and that he must certainly have a tapeworm; aware, henceforward, of the voracity of the imaginary tapeworm, his consumption of food, already twice that of an ordinary mortal, was now fourfold.

In this field, an example of secondary tendencies is furnished by the preferences we show for certain foods, and the dislike we feel for others. Some of these tastes are natural manifestations of individual temperaments; but most of them are simply due to suggestion, and are all the more imperious on that account. The subject declares he cannot overcome his like or his dislike; and he is in fact enslaved by it precisely in proportion to the degree to which he believes himself enslaved—but no more. He "can't bear the smell" of a particular spice, and yet he will go into ecstasies over the flavour of a sauce containing this very spice, when he does not know it is one of the ingredients.

How do we form our tastes as a rule? Let us remember, first of all, that we generally form them in early childhood, the preëminently suggestible age, when we see flying bells (see p. 62), and when our mother's breath will cure a pain. Just as in the case of the boy in whom a terror of toads was aroused by imitation, it will be enough for a child to see an adult display disgust for any article of diet. Henceforward the child will likewise find it disgusting. Children, moveover, incline to like everything that those whom they are fond of like. But if you are in a child's black books, he will detest whatever you say, whatever you do, and whatever you

like. A child is in the sulks and does not want to eat his soup; if now you unfortunately say that the soup is good, the child, who is at odds with you, interprets your saying by contraries, and may even take a permanent dislike to that particular soup.

These remarks do not apply to alimentary tastes alone. Carl Spitteler, in his *Premiers souvenirs*, writes as follows concerning a picture he possessed in childhood:

"Among the animals, I was particularly fond of the spotted hyena, whereas I had an unmeasured contempt for the striped hyena. The cassowary was one of my favourites; I greatly preferred it to the ostrich, for I considered that the latter bird suffered from overweening vanity. These sentiments were the outcome of my caprice. You are always talking about the striped hyena, and that is a good reason for my passion for the spotted hyena. Everyone insists upon the importance of the ostrich. Well, to me it seems a stupid bird; and my heart goes out to the cassowary, which you despise."

Unlike Carl Spitteler, most of us are unable to remember the origin of our tastes, and we therefore believe them to be innate and ineradicable. Nevertheless, some of our tastes do not even date from childhood, and yet their origin is suggestive. After too hearty a dinner, or one day when our stomach is a little out of order, we eat for dessert something we have always liked. Henceforward we find it unpalatable. We think our taste has altered, and from this date it has in fact altered. When we partake of a dish that is new to us, our attitude towards it is usually determined by similar reasons, and promptly the dish is classed among those we like or among those we dislike. Nay more, there are some who "know beforehand" that they will not like this

or that. Naturally these are among the prophecies that bring their own fulfilment. Above all will this ensue if others at table have insisted on the prophet's tasting the undesired food, for then his vanity and obstinacy come into play. With tastes as with opinions, adverse discussion strengthens them.

It is well known, finally, that the far-fetched names with which, in restaurants, commonplace dishes are christened, have a powerful influence in promoting gustatory satisfaction.

There are certain perverse impulses, derived from the nutritive impulse and developed by suggestion. These range from coprophagia, or the impulse to eat excrement, to drunkenness, which is scarcely less disgusting. To this subject we shall return.

When a tendency becomes greatly accentuated, we speak of it as a *passion*. This is exclusive; it occupies the entire being; it is an affective obsession, and suggestion plays the part that it plays in all obsessions. Before it, we are *passive*, we are astounded at our own weakness, and this makes us yet weaker and yet more passive.

Passion has been compared to a fixed idea. Charles Renouvier has thoughtfully termed it "mental vertigo." In any case, when we wish to compare passion with other psychological phenomena, it is the phenomena of suggestion which present themselves to the mind. In the struggle against passion, we once more recognize the futility of effort when this effort is directed in a sense opposed to that of the dominant obsession. The stronger the effort, the less effective it is. As soon as we have realized this fatality, the vertigo becomes accentuated;

it is as if we had to do with a falling body, which traverses distances proportional to the squares of the times occupied since the beginning of the fall. It is only the first step which is difficult. Thereafter, the rapid fall seems to carry us away. That is why "one must not trifle with love."

To express a sentiment one does not feel, is not always to lie, for he who expresses a sentiment begins to feel it. And by reiterating the expression of the sentiment, one may inflame it to a passion. Like the liar who ends by believing his own falsehoods, we are caught in our own snare. "By talking of love," says Pascal,[1] "we fall in love. It's the easiest thing in the world." And later he writes: "One can hardly feign love without being very near to being in love, or at least to being in love somewhere; for this simulation is not possible without having the mind and the thoughts of love." It is always the same principle: "You would not have sought me had you not already found me."

Whatever may have been the primary origin of a passion, we may affirm that its most conspicuous character, that from which its name is derived, its *passivity* (or rather our passivity in relation to it), is considerably intensified by spontaneous suggestion.

Furthermore, the very origin of the passion is in most cases an imitative suggestion. Like the well-to-do idler who studies his own symptoms until he succeeds in discovering in himself indications of all the ills that flesh is heir to, the adolescent, giving free rein to his wandering thoughts, discovers in himself the symptoms of the passion of which he has read so many descriptions. The schoolboy recalls the great passions he has studied, that

[1] Discours sur les passions de l'amour.

of Phèdre, that of "Venus, wholly devoted to running down her quarry"; the girl in the convent school impersonates herself as the heroine of some idyll written for such readers as herself, she is the Clara d'Ellébeuse[1] whose old-fashioned and false idealism arouses the ironical amusement of Francis Jammes; the little servant maid enjoying her first experience of town life, sees everything in the light thrown by sixpenny sensational novels; the street arab's views on life and passion are derived from the cinemas, which allure him by the presentation of figures superhuman in stature but subhuman in soul, the cinemas whose perverse suggestions are a social danger to-day. Each lad and each lass suggests to himself or to herself the form of passion which has presented itself to his or her imagination. Each is stamped, often for life, with the imprint of these early suggestions.

"Great passion," wrote Brunetière, "is as rare as great genius." As a rule, in fact, passion is a mere imitation, an unconscious counterfeit. Religious passions (as in the sixteenth century), patriotic passions (as to-day), flourish by crises, by epidemics. There is a passion of the century, just as there is the comet of a season, just as there is the latest craze or the fashionable dish. Unfortunately, the fashionable dish is often spiced with poison.

This discloses the enormous part played by spontaneous suggestion in the affective life. "Do you mean to imply," the objector will exclaim, "that all our senti-

[1] Clara d'Ellébeuse is a heroine of insipid romance of the type known as "romans pour jeunes filles." Such books were favourite school prizes in the fifties of the last century.—TRANSLATORS' NOTE.

ments, all our tastes, all our passions, or nearly all, are illusory?'' We foresee that the preceding pages will at first leave this impression, but it is a false impression. It arises from the fact that the starting-point of suggestion is imaginative, and that we are apt to look upon the imagination as the faculty of illusions, as ''the mistress of errors.'' This is one aspect of imagination, but it is not the only aspect. If we deliberately confound suggestion and illusion, we do so precisely because we ignore the great power of suggestion, a power which it is our present business to realize. We shall see clearly in the sequel that this power is creative, that it brings into existence the most tangible realities, such as bodily modifications. But, when we think the matter over carefully, we recognize that this creative power is equally manifest in affective suggestion.

The outcome of suggestion may be a state which is in certain respects illusory, as for example when judgments of things are in question. A true judgment must conform to the external reality to which it relates. Its truth contains an objective element. If I suggest to myself that the earth is square, and end by believing it to be square, it is true that I believe it, but it does not follow that the earth really is square, for I am the victim of illusion. A sentiment, on the other hand, is purely subjective. Its whole reality is in itself and in us. When I think that I suffer, I do really suffer; there are no imaginary ills, if by imaginary we mean illusory. A sentiment, a passion, may be the result of suggestion; but they are none the less real. Their essence is to be felt, and felt they are. Therein lies their full reality. Suggestion has veritably created something, for it has given life to a self-sufficient entity.

When a cause which we regard as insignificant brings into existence an effect which we know to be considerable, we must not allow ourselves to depreciate the effect because of our estimate of the cause. On the contrary, we must revise our estimate of the cause, and recognize its high potency.

CHAPTER SIX

ACTIVE OR MOTOR SUGGESTIONS

(Habits, Mediumistic Phenomena; Sayings and Doings, Happenings)

In the tendency, we have the natural stepping-stone from the affective life to the active life. Every tendency desires to externalize itself in action. This brings us to the domain of motor phenomena, where suggestion is expressed by the schematic formula:

The idea of a movement gives birth to this movement.

In practice, moreover, we have as a rule to do, not with a single movement, but with a whole series of movements organized upon a teleological and synthetic principle.

In the last chapter we referred to the perverse tendency known as drunkenness. This tendency is not fully developed unless it culminates in the act of drinking. Nay more, we can only speak of a passion for drink when the acts leading to intoxication are frequently repeated, so that we have, more or less, to do with a habit. As with every habit, the same thing happens as when a piece of cloth takes a fold. The frequent repetition of the action facilitates the particular motor discharge; one who has drunk often, will go on drinking. Now we do not wish to assimilate habit to suggestion; we must continue to employ the word suggestion in the restricted sense we have given to it. Nevertheless, if habit be not identical with suggestion,

the latter is terribly potent in promoting the acquirement of the former. Above all, in the case of drinking, for instance, suggestion tends to impress upon the practice that irresistible and "passionate" character which is typical of what we term drunkenness. The patient, because he has already yielded to his craving, fears that he will yield once more, and this contributes to his repeated falls. The more often his better will has been frustrated in the past, the less his power of resistance in the future. Furthermore, the state of intoxication, like that of reverie, is a state wherein mental control is slackened, wherein the subconscious dominates the mind. Now, as we shall show later, such a state is peculiarly favourable to suggestion. The images which are impressed upon the mind under such conditions have every chance of bearing fruit; and since in this case the images are those of drinking bouts, of glasses filled and drained, images associated with a feeling of enjoyment, we may say that every drinking bout is a suggestion of future intoxication. In addition, as always happens in cases of this kind, effort has a purely negative result, and this contributes increasingly to depress the subject.

An analogous process is at work in the passion for opium or morphine, in that for ether, and in that for tobacco. All of these, in varying degree, are likewise sustained by the state of intoxication which the various narcotics induce; or, to speak more strictly, by the autosuggestion which the state of intoxication facilitates.

The same considerations apply to the abuse of the sexual instinct, whether in normal heterosexual intercourse or in masturbation.

All these bad habits, from the most serious ones, like cleptomania, to the most trifling, like nail-biting, are

sustained and aggravated by spontaneous autosuggestion. It has frequently been pointed out that bad habits are much more easily contracted than good ones. This should suffice, I think, to prove that in the former case suggestion is at work. For the difference is that in the case of the bad habits we usually wish to strive against them, and this, as always happens with suggestion, is an infallible method for engulfing us more hopelessly in the quicksand. Despite the aphorism "who wills, can," we have to do here with cases wherein effort is invariably self-defeated, eventuating always in the opposite of what is desired. This happens because the idea, the suggestion, of powerlessness dominates the mind, and because the effort will always be transformed in the sense of the dominant idea.

Those under the rule of passion, from lovers who desire to be free from the thraldom of love, to drunkards who long to be free from the thraldom of drink, have in all ages derided the vanity of effort. When, in every variety of tone, they are assured that who wills can, they feel that they are not understood, and they turn away shrugging their shoulders. They are perfectly right. It is another cure that they need, and what the cure is we shall learn in due course.

In the sphere of movement, suggestion by imitation is common. Immoderate laughter readily spreads through a crowd; yawning is contagious. If we associate with a person suffering from a habitual nervous movement, we are apt to acquire it ourselves. The rhythmical gait of our companion on a walk leads us insensibly to keep step with him.

During a conversation we discover that our hand,

holding a pencil, is engaged in writing, "mechanically" as we say, i. e. subconsciously, some phrase which was uttered several minutes before; or it is drawing some object which has been within our range of vision, but which we do not even remember having noticed. The auditory image of the words heard, the visual image of the object seen, have been transformed into movement. For such images are motor images. Painters, without being consciously metaphorical, speak of the movement of a line; and in like manner, musicians speak of the movement of a melody. This is not the place to explain the physiological grounds for the complex nature of the images in question. Suffice it to point out that a motor image, evoked by a visual or auditory image with which it constitutes a united whole, has stimulated the brain; in the subconscious it has then been transformed into a real movement, or rather into a complicated series of intelligent and coördinated movements.

We have had occasion to refer to hallucinations which astonish the subject because their cause is unperceived, and which are nevertheless suggestions whose first phase has been subconscious. We even come across cases of subconscious [automatic] writing which is the outcome neither of the words of a recent conversation nor yet of any series of images actually present to the senses or of recent occurrence. Still, as Flournoy has well shown, in many of these cases the process can be reconstructed, and we then learn that here also we have to do with a suggestion of which the first phase (the verbal-motor image) is subconscious. The hand writes phrases which the subject has not foreseen, which astonish him, which conflict with his conscious tastes and his conscious ideas, and which none the less emanate from the depths of his being.

Many cases in which we might have been inclined to suspect "mediumism," i. e. the operation of a mind other than that of the subject, thus prove reducible to manifestations of "spontaneous" autosuggestion.

The phenomena of table-turning, likewise, are in many instances reducible by analysis to suggestions of this order. Often enough, the results of table-turning bring us back to the elementary case of the pencil which traces a word that has just been heard or sketches an object actually in the field of vision. Take for example the following record, made by a good observer actually present at the séance:

"We are seated at the table; our hands resting on it form a chain; for a time nothing happens. Suddenly, one of the legs of the table rises, beats out nine strokes at regular intervals, and then all is quiet again. Not until some time later do more complex phenomena begin. A moment after the nine strokes have been made, I glance at the clock, quite by chance, and I see that it has just struck nine."

Apparently the auditory image of the nine strokes of the clock, occurring in a profound silence and when the minds of the sitters were passive, was able, in the void as it were, freely to develop its motor accompaniments. The associated motor images were transformed into movement in the auditors, or at least in the most sensitive among the auditors (the medium); by the instrumentality of the hands, the subconscious movement was transmitted to the table.

This shows us, in passing, how much caution is requisite in the study of spiritualistic phenomena. Their analysis is exceptionally difficult, seeing that the greater part of the process is subconscious. But I am of opinion

that the methods of psychoanalysis (as applied to the fragmented hallucinations of the lad Amédée) can throw much light on such phenomena, for the primary object of psychoanalysis is, by indirect means, to open a way into the subconscious. Amédée's hallucination is closely analogous to the phenomena to which allusion has just been made; the difference being that in the latter case the suggestion was motor, whereas in Amédée the suggestion was representative.

A spiritualistic séance is extremely favourable to the working of spontaneous suggestion, and this for three reasons. In the first place, a condition of mental relaxation is imposed upon the participants. Secondly, an emotional state is invariably aroused by approximation to the mysterious. Thirdly, there exists an expectation that remarkable things will happen.

Spontaneous suggestion manifests itself, not merely in the production of trifling movements, but also in the initiation of complicated actions; it takes effect, not only in the formation of isolated habits, but likewise in its influence upon character, which is a bundle of mental habits.

More or less unconscious actions, due to involuntary imitation, are of frequent occurrence. We have the poor sheep of Panurge; and we have heroic charges in the battlefield. In the latter case, the intoxication of the firing, of the clamour, and sometimes of alcohol systematically distributed, induce the requisite hypnoid state. In a cavalry charge, the horses are subject to it no less than the men.

In so far as imitation is not fully conscious and deliberate, it is invariably a manifestation of suggestion. The child, in most cases, has no idea why he chooses to play

one game or another, but the idea is implanted in his mind by imitation. He does what he has seen others do, though he has sometimes forgotten having seen them.[1]

A year or two ago I carved a device on a tree.
The tree has made it its own, and thinks that it improvises.[2]

We all resemble that tree. And like the tree, between one year and the next we have grown; the device, the imprint, let us say the image graven upon our minds, has grown likewise in the subconscious. A slight trace made upon our life in childhood will in later days become a deep impression. We tend to act as we have seen others act, above all when the model has been forgotten. So long as we still remember our model, we know that we are imitating when we do as the model did. We know that the action does not emanate from ourselves, and before doing it we supervise the intention and discuss it. But when the model has been submerged in the subconscious, we imitate while thinking we "improvise," and we no longer discuss. Or, if we do discuss, the subconscious, teleological as ever, provides us with all kinds of excellent reasons for doing what it wishes us to do, when the only real reason is the presence in the subconscious of an image or a system of images which the conscious mind knows nothing of.

Psychoanalysis, though a very recent development, has already clearly revealed the action of suggestions which date from early childhood, their action upon the subject's whole life, upon his character, upon his innocuous or dangerous manias. It is no longer possible to

[1] Cf. Bovet, L'instinct combatif—the chapter on the part played by example.

[2] Victor Hugo.

LEGISLATIVE LIBRARY

doubt that for most of us the choice of a career is determined by infantile suggestions, which are often masked by the operation of the strange law of transference, but which are none the less discoverable. Furthermore, these are not simply motor suggestions, for with them are mingled affective elements. We tend to imitate what we like or what we admire. The dazzling epaulets of an indulgent uncle will, twenty years later, lead the nephew to embrace a military career, believing it to be "in the blood." An only child, whose parents are elderly and who have retired from active life, will perhaps know no other world than that of the school, and will perhaps admire no other dignity than that of the schoolmaster; these circumstances determine his choice of a profession; but after he has himself become a schoolmaster he is greatly astonished when psychoanalysis reveals to him the real reasons for his adoption of this "calling."

Psychoanalysis has clearly demonstrated that the phenomena and doings of everyday life, the utterances made in the most casual conversation, are powerful revealers of what, quite unknown to the subject, is going on in the subconscious. These phenomena, these doings, these utterances, are a clue to all that is most vigorously censored, to all that is hidden in the abysses of the mind; in especial are they this when they are least subject to our conscious supervision. Régis and Hesnard[1] give a number of examples taken from the various authors who originated this method.

"A well-bred man enters a room and greets everyone politely, with one exception, which is quite unconscious. Now the person overlooked is the son of a man of busi-

[1] Op. cit.

ness who has refused the newcomer's services as commission agent.

"Here are other examples: mistaking the hour of the train in a journey taken unwillingly; losing a present given by a friend with whom one has quarrelled; forgetting the name of a friend whose image is associated in our mind with that of someone whom we dislike; the involuntary spoiling of an object when we should like to replace it by a new one. In the same category come involuntary exclamations, blunders made from absence of mind, and the saying of 'yes' for 'no' when our real thought is in opposition with what we wish to say. During a psychoanalysis where sexual errors are in question, to play with a money-box may reveal a habit of masturbation. Every gesture of the patient under examination must be carefully noted, for every gesture may be a significant symptom.[1]

"Undesirable actions of a very grave character may be the work of the unconscious. Freud believes that in many cases death from accident, rashness, mistake, etc., is in reality an involuntary suicide dependent upon a complex."[2]

This proves that our ordinary sayings and doings are intimately related to our subconscious, and continually betray its thoughts. If we compare the censorship to a

[1] When collated with the results of other psychoanalytic methods (the study of dreams, reminiscences, etc.). Thus only can chance coincidences be excluded.

[2] It is possible that the death of Verhaeren, the great Belgian poet, was of this character. He was killed by a train in Amiens station. Again and again he had sung the horror and the beauty of railway trains, in language which reveals a very profound complex.

dam which retains a mass of mental material within the subconscious, we may say that spiritualistic manifestations, and hallucinations like those of Amédée, are the result of sudden breaches in this dam, the outcome of irruptions from the subconscious into the conscious. But the before-mentioned casual everyday sayings and doings are the expression of the continual escape of surplus energy from the subconscious, by way of the channels provided for normal overflow. If this be so (and psychoanalysis proves that it is so), we may infer that suggestions, in the second phase of their activity, having accumulated in the subconscious, must unceasingly utilize this means of escape in order to secure fulfilment. Since their action is teleological, and since to them all means are good which promote the attainment of the goal, we can foresee that from moment to moment they will inspire in us the movements, the actions, and the words which tend towards the ends in view, which favour realization.[1] Henceforward, everything must happen as if suggestion were in command of events. When we set out to do something with the preconceived idea, or with the fear, that we shall be unable to do it, everything will happen as if we were trying not to succeed. Unwittingly to ourselves, our dominant idea will inspire all the sayings and all the doings that are necessary to counteract our ostensible purpose. Nay more, in virtue of the law to which we have frequently referred, the stronger the efforts we make for success, the more unmistakably

[1] If the subconscious, as other facts suggest, is in possession of knowledge and of memories unknown by the conscious self, we can be sure that the subconscious will display remarkable sagacity in the choice of means of this character. Extraordinarily accurate realizations will ensue.

shall we favour failure. And thus it goes throughout life.

A posteriori, experience teaches that things happen just as we have described. American writers are fully convinced of the fact by direct and practical observation of social life.

Emerson, the great pioneer in preaching the gospel of moral force, wrote as follows in days when the doctrine of suggestion was still unknown:

"He [man] thinks his fate alien because the copula [between person and event] is hidden. But the soul contains the event that shall befall it; for the event is only the actualization of its thoughts, and what we pray to ourselves for is always granted. The event is the print of your form. It fits you like your skin. . . . A man will see his character emitted in the events that seem to meet, but which exude from and accompany him. Events expand with the character."[1]

By recent American writers this idea has been developed into a veritable system.[2]

Orison Swett Marden, in his highly figurative language, writes as follows:

"To be ambitious for wealth and yet always expecting to be poor, to be always doubting your ability to get what you long for, is like trying to reach east by travelling west. There is no philosophy which will help a man to succeed when he is always doubting his ability to do so, and thus attracting failure. . . .

[1] Emerson, The Conduct of Life, Chapter I, Fate, Riverside Edition, Routledge, London, 1883, pp. 43 and 45.

[2] These authors, who often wander into the region of mysticism, have founded a school which is transitional between the first Nancy school and the New Nancy School.

"You will go in the direction in which you face. . . .

"There is a saying that every time the sheep bleats it loses a mouthful of hay. Every time you allow yourself to complain of your lot, to say 'I am poor; I can never do what others do; I shall never be rich; I have not the ability that others have; I am a failure; luck is against me,' you are laying up so much trouble for yourself. . . .

"No matter how hard you may work for success, if your thought is saturated with the fear of failure, it will kill your efforts, neutralize your endeavours, and make success impossible."[1]

Herbert Parkyn explains these phenomena as follows:

"You may dislike a person, but for reasons politic you determine not to show your dislike. You may even go out of your way in an endeavour to make yourself agreeable to the object of your dislike; still in some way or other a coldness will spring up between you, and the dislike becomes mutual and may end in an open rupture without either person being able to explain how the dislike was uncovered. The explanation is simple. Thought takes form in action, and the dislike will so influence your actions that you will betray yourself by a look or a nudge or some other unconscious slight. The action may be wholly involuntary or unconscious on your part, and it may be just as unconsciously noticed on the part of the other person; but his involuntary mind takes cognizance of the action, the seed of discord is sown in his mind also, and the damage is done.

"Similarly you may cherish a strong desire to go somewhere, to do something, or to possess something. You

[1] O. S. Marden, The Miracle of Right Thought, Rider, London, 1913, pp. 46-8.

may not deem your desire reasonable nor within the realm of possibility at the time, but your actions, conversations, and decisions will be influenced by this desire in various ways. Although it may take years for you to gratify your desire, still that desire is usually gratified by the opening up of ways and means, and this opening up, although it may appear accidental, is, nine times out of ten, the direct result of actions unconsciously performed through the promptings of your desire."[1]

Strictly speaking, however, these phenomena might be regarded as no more than coincidences, and the above explanation might be looked upon as nothing better than a plausible hypothesis. But as soon as we compare them with the precise interpretations of psychoanalysis, the gap is filled and the doubt vanishes.

We now understand how our own mental attitude leads to success or failure. We grasp the secret of "luck," good or bad; and we realize why those who believe in their fortunate or unfortunate star are rarely given the lie by the facts. This fatality exists, but it is internal and not external; just as the fatality of a habit or a passion is internal when we wish to overcome it but are unable to do so. We hold the key to this determinism. As soon as we know how to make use of the key, we escape from the dominance of fate, we win freedom. Our star is in ourselves, and upon ourselves does it depend whether the star is lucky or unlucky.

[1] Op. cit. pp. 113, 114.

CHAPTER SEVEN

MOTOR SUGGESTIONS
(continued)

(Functional and Organic Modifications, Maternal Impressions, Cures)

ALL the motor suggestions hitherto considered are related to movements which can be carried out under the full control of the conscious self. Suggestion here does no more than follow the path trodden by the will. In many instances, identical phenomena can be voluntarily reproduced. We may feign to yawn; the actress who plays the part of Juliet's nurse learns to laugh immoderately. In the case of mediumistic phenomena (automatic writing, for instance), the subject may cheat.

There are, however, other motor autosuggestions which act on muscles that are not subject to the control of the conscious will, the muscles which regulate (or fail to regulate) the visceral functions. The same remark applies to those imperceptible movements on which the most profound organic modifications depend. Suggestions of this category, methodically applied in the form of reflective or induced suggestions, constitute the basis of psychotherapeutics, of a system of psychotherapy characterized by extreme potency, compared with which all that has hitherto been effected by ordinary hypnotic suggestion will soon appear to have been of a very elementary order. Indeed, to those who have closely fol-

lowed the latest acquirements of the New Nancy School, it is already plain that ordinary hypnotism represents merely the infantile stage of the art of psychotherapeutics.

In all ages, unofficial healers have obtained remarkable results in cases where orthodox medical skill has failed. This gives cause for thought. How do these healers effect their cures? They do not directly apply suggestion as ordinarily understood; but they are backed by a great reputation, due to chance or to legend; people believe in them; and they make use of fantastic methods, whose strangeness and illogicality arouse a sense of the marvellous, producing in the patient an emotional state which facilitates the working of autosuggestion. In these conditions, faith cures.

We have no right to deny the reality of "animal magnetism," or to deny the curative effects of "absent treatment," but there can be no question that many of the cures attributed to animal magnetism or to absent treatment are in truth the outcome of spontaneous autosuggestion.

Coué has proved this over and over again. Telling a patient that he will think of him every evening at a fixed hour, he requests the sick man to collect his thoughts at the specified time, and to put himself in mental rapport with his doctor. The value of the treatment, he is told, will speedily become apparent. The patient obeys orders. At the appointed hour, Coué is gardening or fishing. Nevertheless, after a few "sittings," a cure ensues. Sometimes it deserves to be called a "miraculous" cure.

At the outset of his studies, Coué tells me, he noted the cure of an extremely refractory illness, when the patient, on his advice, took a new patent medicine. Greatly

astonished at the result, he analyzed the medicine, and found that it was a harmless compost, whose whole value was based upon skilful puffery—and above all, as he learned in the sequel, upon the involuntary eloquence with which he himself had advised the use of the remedy and upon the patient's confidence in him and his word. Hence germinated in his mind the idea that suggestive treatment might prove valuable in organic maladies. This idea was to be independently confirmed by the work of Bonjour, of Lausanne.

Warts are peculiarly responsive to autosuggestion; and it was to warts, in this connection, that Bonjour first devoted his attention. In the Swiss canton of Vaud, curers of warts abound; and here it sometimes happens that the patient will employ a famous prescription without troubling to consult the healer. In these cases, autosuggestion is seen in all its beauty. Prescriptions pass from village to village and from hamlet to hamlet. Some of them are incredibly quaint. For example, to cause warts, the subject goes out one evening, moistens the tip of the finger, looks at a star, and simultaneously applies the wet finger-tip to the other hand. The operation is repeated, the finger being freshly moistened with saliva each time, while the subject counts "one, two, three . . ." up to the number of warts desired. Now, wherever the moistened finger-tip has been applied, a wart duly appears. I do not guarantee the alleged numerical precision, but the development of warts as a sequel of such practices is a proved fact. The Vaudois girls are very fond of this amusement—not for the mere pleasure of having warts (for the pleasure of their possession is certainly open to dispute), but for a pleasure which to them is very real and very great, the pleasure

of passing them on to someone else. A ribbon is tied round the affected hand, and is knotted as many times as there are warts on the hand; then the ribbon is dropped on the highway. Whoever picks it up and unties the knots, will get the warts, and the original owner of the warts will be cured. Another prescription, equally efficacious, is to rub the warts with a piece of bacon rind, which is subsequently placed beneath a stone, on damp ground. As soon as the bacon rind is rotten, the warts will be cured. But if, by bad luck, someone moves the stone, one has wasted one's pains and one's bacon rind, and one must begin all over again.

In the same canton, persons suffering from dropsy are cured by lying on two mattresses between which some toads have been placed.

The value of such methods depends upon their illogicality, their strangeness, which strikes the imagination of the simple, monopolizes the attention, and fills the mind with a sense of mystery.

To close this series of laughable examples, I will quote a picturesque case reported by Gillet, one of Coué's pupils. An asthmatic, on a holiday journey, was awakened in his hotel by a violent paroxysm of the disease.

"Greatly distressed for breath, he got out of bed and hunted for the matches. He had a craving for fresh air, but could not find the window. 'Confound these third-rate hotels, where one gropes vainly in the dark!' He is suffocating, and he clamours for air. Feeling about, he at length finds a pane of glass. 'Damn it all, where's the window-bolt? . . . Never mind, this will do!' and he breaks the pane. The fragments fall to the floor. Now he can breathe; again and again he fills his chest with the fresh air; the throbbing at his temples passes,

and he goes back to bed. 'Saved!' . . . Next morning, one of the items in his bill was, 'Broken clock-case, fr. 4.35.' "[1]

More extensive modifications, such as can only be effected by a considerable amount of work within the organism, are presented by the cases (now beyond dispute) in which the imagination of the mother influences the fœtus.

Observers worthy of the utmost confidence, from Darwin to Liébault, have in this connection reported definite data, which must be regarded as classical. Darwin records that a child resembled in every feature a girl of the neighbourhood to whom the father had been making love during the mother's pregnancy. Liébault mentions the case of a vinedresser who was exactly like a statue in the village church, the statue of the patron saint of the village. During her pregnancy, the man's mother had been obsessed with the idea that this would happen. But I propose to quote the detailed account of a recent instance recorded by Artault:

"During the second month of her pregnancy, a young woman was visited by a friend of her husband. She had never seen the man before (your readers are so sceptical, that I must be precise on this point). She was greatly struck by a malformation in the nail of his left forefinger. The nail was thick and curved, so that it was like a lion's claw. The deformity was the sequel of an ordinary accident, in which the terminal phalanx of the forefinger had been crushed. The young woman's mind became obsessed by this deformity. The friend was staying in the neighbourhood for several months, and every

[1] Gillet, L'auto-suggestion, Bulletin Ecole de Nancy, 1913.

time he came to dinner the expectant mother was unable to take her eyes off the finger, for she was terrified lest her child should be born with a similar finger-nail. She was haunted by the fear to such an extent that her husband in the end begged his friend to wear a glove when the wife was present. But, alas, the impression on the fœtus had already been made, and when the baby was born at term (once more, I am precise) the left index finger had a claw like that of the unlucky visitor. The child was a girl whom I see very often. Whenever I look at her clawed finger, I compare it mentally with that of the model, whom I have also seen. Before the experimental certainty of this instance of maternal impressions, which is on quite a different plane from old wives' tales of birthmarks, I smile at systematized incredulity. I am unable to explain it, but I record it.''[1]

In recording facts of this nature it is usual to insist upon a fixed idea, a haunting, an obsession, as the starting-point. The mother's spontaneous attention has been obstinately fixed on an image, and by a delicate and complicated motor process this image is realized within the organism. There can be no doubt that the occurrence is favoured by the heightened emotional susceptibility characteristic of pregnancy. If we compare suggestions of this order with those realized during hypnotic sleep (such as the case reported in the Introduction), we see that whereas we were formerly concerned with functional changes, we now have to do with organic changes. Here, then, autosuggestion is at work in all its power.

Analogous phenomena, though less marked for the most part, are observed in connection with a great many births. We are no longer entitled to attribute them to

[1] Artault, Chronique médicale.

mere coincidence. We must rather hold that nothing more is requisite to produce them than an abnormal or exceptionally sensitive temperament. Once more, it is the task of psychoanalysis to verify the hypothesis that a large proportion of the stigmata wrongly ascribed to heredity, are really due to fear, to a superstition regarding heredity that exists in the mother's mind. The high degree to which the mechanism of childbirth can be influenced by the activity of the brain (a sensibility proved by the instances previously recorded) compels us to believe that when a pregnant woman is obsessed by the idea that her child will display some parental stigma, the chances are considerable that this will actually happen. When suggestion is better understood, and when a knowledge of suggestion has been more widely diffused, the superstition of heredity, as disseminated by nineteenth-century science and as taught by Zola in his novels, will receive a deadly blow—not indeed as regards the primary principles of the theory, but as regards many of its premature applications. For there are three kinds of suggestion which reinforce one another in the simulation of heredity: first of all, there is suggestion acting on the fœtus; secondly, there is the imitative suggestion which is one of the laws of the development of the child; and lastly, in the adult, there is the superstition that heredity is "inexorable"—a superstition no less erroneous than the belief in miraculous cures, and just as disastrous as the latter is often beneficent.

In like manner, psychoanalysis will doubtless verify with increasing frequency the hypothesis that many miscarriages, and many difficult deliveries, are chiefly due to maternal autosuggestion. The starting-point in these cases may be a fear of such occurrences, coöperating with

an unavowed anticipatory hatred of the expected child; or it may be some other repressed wish, of which the conscious ego knows nothing, such as the desire that the birth of a living child shall not take place, this desire being the outcome of a more or less unacknowledged hatred of the father, transferred, without the knowledge of the subject, to the coming infant. But the fear of difficult delivery seems to be the commonest cause of such troubles. I have noted the following instance, in the course of a psychoanalysis.

A young woman, mother of a child of seven, had since the birth of this child suffered from nervous troubles which her doctors had several times declared to be amenable to psychoanalytic treatment. I begin, in accordance with the usual method, by asking her to tell me of some dream, recent or otherwise, which had particularly struck her. Unhesitatingly, she described a dream dating from seven years before, and, in the course of the conversation, she spontaneously told me that it had happened during her pregnancy. It must have made a profound impression on her mind, seeing that the memory was so vivid and so promptly recounted. Moreover, there could be little doubt that the dream was directly related to the pregnancy.

In the dream she was at the town hall. The mayor was away, and the patient's husband was acting as his deputy. A stranger suddenly appeared, a man of crafty and disagreeable aspect. He was a foreigner, apparently of Hungarian and Italian extraction, and he wanted the authorization necessary for residence in Switzerland. Her husband begged the stranger to await the mayor's return, but the man grew impatient, brandished a dagger, chased the husband into the street, and wounded

him. The young woman now found herself at the window, looking down anxiously into the street where this was happening. The mayor appeared beneath the window, saying to her: "Nothing serious will happen, as long as you don't come down; be careful, and everything will be all right." Then she saw her husband lying in a bed which was the replica of her own. He had a bleeding wound in the forehead.

Examining the patient by the association test, I now discovered that the mayor resembled the doctor who was attending her during her pregnancy, so that in her dream the mayor symbolized the doctor; this explained the advice given towards the end. In like manner, the foreigner was the coming child, the intruder.[1] The dagger and the wound symbolized the pains and the bleeding associated with the childbirth she so greatly dreaded. By symmetrical transference, the wound was transferred to the father, to the father's *forehead,* the site of the wound being a characteristic instance of the working of the endopsychic censor. To sum up, the young woman had an intense and all-pervading dread of the ordeal she had to endure; she anticipated disaster. Her fears were realized. The expected stranger was born before the doctor arrived, and the mother had a serious flooding.

This dream discloses a mental condition extremely favourable to the working of suggestion: the vividness with which it was remembered showed that the patient's attention was acutely concentrated on her experiences; and the distressing nightmare proved the existence of

[1] This stranger had to cross a frontier before entering her world, like the Hungarian or the Italian who comes to Switzerland.

an emotional state. We have here a further instance in which the first phase of suggestion was subconscious, was repressed, so that (as in the hallucinations of the lad Amédée) by symbolism alone was it revealed to the consciousness of the subject.

I give another experience of psychoanalysis.

A young woman, whose first marriage had been extremely unhappy, was looking forward to a second marriage, in which she hoped to find happiness. From the moment when this new prospect opened, menstrual irregularities, from which she had formerly suffered but from which she had long been free, reappeared. The analysis showed that the promised destiny seemed to her "too beautiful," so that she could not believe it would ever be fulfilled. She dreaded that some obstacle would intervene, and, above all, that her health would stand in the way; this fear tended to realize itself through autosuggestion. But the analysis, disclosing the cause of the trouble, promptly neutralized it.

A simulation of pregnancy may result from suggestion. Pierre Janet has observed an instance of it in a hypnotized subject. The condition was due to an autosuggestion grafted on a suggestion made by the operator.

"I suggest to Rose that we are not in 1888, but in 1886, and that the month is April. My object is merely to note the modifications of sensation that may ensue. The result is remarkable. She groans, complains of fatigue, of inability to walk. 'Why, what's the matter with you?' —'Oh, nothing; it's natural to my condition.'—'What do you mean? What condition?' She replies by a gesture, pointing to her abdomen, which has suddenly become distended by an attack of hysterical tympanites.

Unwittingly, I have brought her back by suggestion into a period when she was pregnant."[1]

Furthermore, suggestions of this character may arise in the normal waking state. A woman who dreads being pregnant may present all the signs of pregnancy, deceiving herself in the matter; or, if she has never been pregnant, she may present what she imagines to be the signs of pregnancy.

Louis Rénon[2] has endeavoured to ascertain the part played by spontaneous suggestion in the treatment of chronic pulmonary tuberculosis. A careful interpretation of statistics has enabled him to present precise numerical results, so that his inferences have a solidity which is always lacking in a purely narrative record. His conclusions, therefore, are worth recording in full.

"A comparison of the results obtained by the various methods of antitubercular treatment, shows that these results are practically identical in all cases. Whatever the treatment, there is the same percentage of improvements, the same percentage of cures, the same percentage of arrests, the same percentage of cases in which the patient grows worse. Laumonier, my colleague and a fellow-member of the Therapeutical Society, showed a few years ago that in four different methods of treatment the percentage of cases cured or alleviated ranged from 65% to 71% while the percentage of cases in which there was no improvement or in which the patient grew worse ranged from 29% to 35%. There is always the same proportion of satisfactory results, whatever method of

[1] Pierre Janet, L'automatisme psychologique, Paris, 1889.

[2] Le monde médical, January 15, 1914; Bulletin Ecole de Nancy, 1914.

treatment is employed. I have described this proportion as 'the normal coefficient of amelioration'; and I have formulated the following principle:

"Every new method for the treatment of chronic tuberculosis, provided that it is harmless, will give satisfactory results.

"Here we have an absolutely true axiom. I should like to see it stamped in large letters on the cover of every new work upon phthisiotherapeutics; for unless it be taken into account, the accurate appraisement of antitubercular medication becomes difficult or impossible. Before we can venture to say that a method of treating tuberculosis is valuable, the treatment must have been in operation for a period exceeding that of the normal coefficient of amelioration, which is as a rule about three weeks; the treatment must have stood the test of time; it must have been applied to the same patient by different physicians; it must have unquestionable experimental value. Then only are we justified in asserting that the remedy is genuinely antitubercular.

"Why is there this normal coefficient of amelioration? The matter is quite simple. Whenever a method of treatment is recommended by a doctor who believes in the value of his own advice, there ensues in the sufferer from chronic tuberculosis a psychotherapeutic state, a state tending to promote cure. This state is the same, whatever the nature of the treatment. The patient accepts the suggestions of his medical adviser, and the particular medication is no more than the vehicle of suggestion.

"Albert Mathieu, in a paper which throws much light on the general problems of therapeutics, has recorded the influence, upon tubercular patients in hospital, of

the hypodermic injection of cubic centimetre doses of physiological serum, which is given the imposing name of antiphymosis. The patient is told that the serum in question is a new and most valuable discovery; and after his mind has been prepared in this way, an injection is administered daily for five or six days. The cases were carefully selected, and the results were accurately noted day by day. They surpassed all expectation. Within a few days, appetite returned; there was less cough, less expectoration, there were fewer night-sweats; there was even an improvement in the pulmonary physical signs; there was an increase in weight, ranging from three to six pounds. But all the old signs and symptoms recurred immediately when the injections were discontinued.

"'Tubercular patients,' writes Mathieu, 'gain vitality directly anything is done for them; their courage rises and hope is reborn.'

"The most renowned phthisiotherapeutists are those who have great personal influence over their patients; those who have thoroughly entered into the patient's mind and feelings, those who as it were hold the patient in the hollow of their hand; those who guide the patient in accordance with the latest principles of the struggle against tuberculosis, and have grasped all the resources available for that struggle; those who can reinforce their medication with a strong dose of suggestion."

Further examples might be given, but they would teach nothing more concerning the causes and effects of motor suggestion. Anyone who desires picturesque illustrations of its laws, should turn to a remarkable work by Duchatel and Warcollier, entitled *Les miracles de la*

volonté.[1] From the scientific point of view, the writers' methods of exposition are not invariably above reproach. Nevertheless, Boirac, a man of science and philosopher of established reputation, has thought fit, with good reason, to contribute a preface. For, in spite of dubious theories and hasty conclusions, the book displays considerable learning and has indisputable evidential value. It contains abundant records, derived from the writings of distinguished observers of our own day and of earlier days. It is a storehouse, and we need merely open the door. Phenomena of this character, reported as isolated incidents, always have the aspect of anomalous freaks. We advance a step by bringing them together in a collection.

Let us first consider the cases of *dermographism*, in which an image existing in the subject's mind becomes outlined on the skin. The authors make a passing reference to the witches of the middle ages upon whose backs, it is asserted, the word "Satan" was inscribed. They pass to a contemporary and precise report quoted from Charles Richet. A mother is watching her child at play. Accidentally the child unfastens the catch suspending a heavy sliding door in front of the fireplace, and is in danger of being guillotined. The mother's heart leaps to her mouth, and then, in a moment, there forms round her neck—the threatened part in the child—a raised erythematous circle, a weal which endures for several hours. Here we have a striking instance of the power of emotion. Another case is that of a little girl upon whose skin appears the answer to the sum she is trying to do. In this instance the image which gave rise to the suggestion was subconscious.

[1] Durville, Paris.

From dermographism we pass to *stigmatization*, the latter being merely a variety of the former. Stigmata appear on the skin of certain mystically inclined persons, appear in the places where Christ was wounded. These phenomena can be reproduced experimentally. As regards spontaneous stigmatization, we are not solely dependent on the account of semi-legendary figures in remote antiquity; accurate observations have been made upon modern stigmatists, like Louise Lateau and Catherine Emmerich, with sphygmographic tracings and other precise details. In the case of Catherine Emmerich, the circulation was directly controlled by autosuggestion, the blood being distributed as it would have been distributed in an actual crucifixion.

Next, in the world of Islam, we read of the ordeal by fire, of the devotee whose hand is not burned by the hot iron; and we read of the ordeal by sword, which will not draw blood. The authors give a number of instances in which obstinate maladies were cured by spontaneous autosuggestion, the outcome of some novel and striking method of treatment. Of exceptional interest is a quotation from Cabanès, professor at the university of Liége. This dates from 1912.

The book is fascinating, and is full of matter. We unhesitatingly refer our readers to it, though we are far from endorsing all the author's interpretations. We must, moreover, call attention to the misleading character of the title. Instead of speaking of the miracles of the "will," Duchatel and Warcollier should (with O. S. Marden) have referred to the miracles of "thought." Failing this, they should have made it perfectly clear that the will of which they write corresponds to what Schopenhauer termed the "unconscious will," so that

the subject has the impression that what happens takes place outside the domain of *his* will, by a purely spontaneous process.

The most extraordinary among the suggestions recorded in *Les miracles de la volonté* differ only by their extremely picturesque character from those which have been analyzed in the preceding pages. In fact, they do not imply any profounder changes in the organism. It would be an error to look upon them as, in essence, manifestations of an exceptional or morbid temperament. We need not go to religious devotees or to persons suffering from grave hysteria, when we are looking for instances in which suggestion leads to organic modifications. We shall realize this more clearly when, day after day, we have seen such organic modifications produced to order, as the outcome of reflective or induced suggestion.[1]

[1] To this series of examples, we might add those of "suggestion which kills." A nun, whose case was noted by Coué, was confined to bed by illness during the winter. She heard or imagined she heard her doctor murmur, "She won't outlive April." This idea became fixed in her mind. Nevertheless, for the time being she got better, left her bed, and seemed quite strong again. But to every visitor she said, shaking her head, that she felt sure she would die in April. On April 1st her appetite disappeared as if by magic. A few days later she took to her bed once more, and died shortly before the end of the month.

Tolstoi, in his later years, declared that the number 7 was fatal to him. On November 7, 1905, in his Readings for Every Day of the Year, he gives a number of thoughts on death. On November 7, 1910 (O. S.), he died after a few days' illness, although his condition "had not seemed grave."

Recall, further, the case of the man sentenced to death, who was told he was to perish as the victim of a scientific experi-

In conclusion we have to note that there is no radical difference between the action of suggestion when its results are purely functional, and its action when its results are organic. If we admit that suggestion can act in the former cases (and this has long been admitted), there need be no difficulty about acknowledging the reality of its action in the latter cases. For certain persons of pseudo-scientific mind, persons who regard as "incomprehensible" everything which disturbs their habits of thought, the organic effects of suggestion are "inadmissible" until they have seen these effects experimentally verified—and even thereafter. Such persons are extremely illogical. They admit that suggestion acts on the circulation, on the secretions, and in a localized fashion upon various parts of the body, doing this through the intermediation of the vasomotor nerves. Now let us suppose that the vasomotor mechanism stimulates or restricts the circulation through the capillaries supplying some particular group of cells, and that this action is *persistent*. Thereupon the cells of this group will, as the case may be, enjoy an excess of nourishment, or will be insufficiently supplied. They will prosper, like parasites; or they will atrophy. The suggestive action which manifests itself in the case of tumours, local malformations, etc., can be very simply explained on these lines, without having recourse to any laws other than those with which we are already familiar.

ment. A harmless prick was made in each of his limbs; a tap was turned on in the room and he was told the water running was his blood flowing from the wounds; believing this, he died.

See, finally, Freud's opinion (quoted on page 99) that death may be caused by a subconscious complex.

CHAPTER EIGHT

CONDITIONAL SUGGESTIONS

We have finished the analytical exposition of the phenomena classified in the scheme we drew up at the beginning of Chapter III; we have discussed representative suggestions, affective suggestions, and active or motor suggestions.

A special chapter must now be devoted to what may be termed *conditional autosuggestions,* the autosuggestions which are the realizations of an idea that may be formulated as follows: "Every time that so-and-so happens, so-and-so will follow."

Practitioners of hypnotism have long been familiar with "posthypnotic suggestion." Having induced sleep, they order the subject to do some fantastic thing after he has awakened; or they tell him to come back in a week or a fortnight. The subject obeys the suggestion, without knowing why, for he thinks he is actuated by his own will, and finds excellent reasons for what he does. The means employed by the subconscious teleology, for the justification of the act, are often remarkably subtle. A young man to whom I had suggested that on awaking he should assume the traditional Napoleonic attitude, with the arms folded on the chest, began, when awakened, by expressing his astonishment at all the phenomena which had just taken place. His surprise became more and more intense, until at last, exclaiming, "Look here, this is a bit too thick!" he folded his arms in an appropriate pose. Now the astonishment van-

ished; with crossed arms he stood in statuesque immobility; behold Napoleon! The gestures of astonishment had been the justificatory means. The subconscious had utilized astonishment, the subject's actual state of mind, and had modified it in the direction of the suggestion which was to be realized. This is, in a sense, analogous to what takes place in hallucination by compromise.

Posthypnotic suggestion may take a conditional form. We may command the hypnotized subject to have this or that idea, to execute this or that gesture, whenever this, that, or the other happens. . . . By this method we may make the patient remember the draught he has to take every time he sits down to a meal.

But such posthypnotic suggestions are in most cases valid for a brief period only. As the interval increases, as the impression received during the induced sleep gradually fades, they become inefficacious.

Nevertheless, there also exist *conditional spontaneous autosuggestions,* and these may remain in force for an indefinite period, until they are inhibited by a counter-suggestion. They may last for years, for an entire lifetime. This is strongly confirmatory of our thesis that autosuggestion is in reality the type of all suggestion; that hypnotic heterosuggestion is no more than a reproduction of autosuggestion, a reproduction that is often attenuated, fragile, and unstable.[1]

[1] In Auguste Forel's opinion, curative heterosuggestion is durable in two cases only: first, when there is no reason why the material cause of the trouble should recur; and, secondly, when the heterosuggestion perpetuates itself in the subject "as a habit and as an autosuggestion." It is obvious that Forel was a precursor in expounding the theory of autosuggestion brought forward in the present work.

If hypnotic heterosuggestion was the first form of suggestion to attract attention, this is because the idea which forms its starting-point, though forgotten by the subject, is clearly remembered by the physician. The hypnotizer, in fact, being aware that he was making an experiment, noted all that happened with great care. Moreover, the number of the ideas proposed by him to the subject was strictly limited; they constituted a few shining points upon a dark background; consequently they were easy to remember.

On the other hand, the ideas from which our spontaneous autosuggestions are derived, are lost amid the vast swarm of incidents that fill the busy life of our consciousness. Nay more, as we have seen, our consciousness is quite ignorant of some of them. Take, further, into account the effects of repression (to which we referred at the outset), and it will be easy to understand why hypnotic heterosuggestion, though infinitely less important than spontaneous autosuggestion, was the first to be discovered.

Confirmation of the foregoing is furnished by the following examples, which Coué has gleaned for me from his vast experience. The proof that we are concerned with pure conditional autosuggestions, with phenomena that are not determined by any organic lesion whatever, is given by the fact that in every case the trouble disappeared IMMEDIATELY after a single countersuggestion. This was the criterion by which Coué was guided in the choice of his examples.

Case 1.—Madame N. of Nancy, travelling from Nancy to Sainte-Menehould to visit her son, became ill when the train was passing through Troyes, and vomited repeat-

edly. Henceforward, EVERY TIME she made the same journey, she was again attacked by vomiting while passing through Troyes. (Cured after one sitting.)

Case 2.—For six months, a young girl had lost the use of her right hand. EVERY TIME she tried to take hold of anything, a contracture of the hand took place, the spasm passing off directly she discontinued the attempt to use the hand. (Cure after a single sitting.)

Case 3.—A young man eighteen years of age, living near Nancy, had a hysteroid crisis EVERY morning, directly he got out of bed. (Cure after a single sitting; kept under observation for a long time; no relapse.)

Case 4.—I give this in Coué's own words: "Z., of Troyes, a man of about forty, suffering from heart, liver, and kidney troubles; had been confined to his room for more than a year, bedridden for the most part. One day, five months before I was first consulted, the patient was seized at five o'clock with a violent paroxysm of dyspnœa, and imagined from moment to moment that he was dying. Various remedies used by his doctor failed to give relief, and the crisis continued until half-past nine in the evening. Next day, towards half-past four, the patient said to his wife that the paroxysm would shortly recur, and in fact, when the clock struck five, the dyspnœa returned in full force, passing through exactly the same phases as before, and subsiding at half-past nine. Henceforward the crises recurred daily, WITHOUT EXCEPTION, for five months. When the man's wife came to see me, and told me the history of his sufferings, I assured her that in my opinion it would not be difficult to cure him of the paroxysms, for it was obvious to my mind that they were unconsciously induced by the patient himself. I begged her to bring

him to my consulting room next day at two. He arrived at the appointed hour, in a carriage. Several other patients were present. I asked Z. to take a seat, and to watch what was going on. I would attend to him, I said, when I had done with the others. Having put my patients to sleep (for at this time I still continued this practice, which I have since abandoned), I began to make general suggestions to them. Turning round while I was speaking, I perceived that the sight of the others sleeping had induced sleep in Z. Having continued general suggestions for a time, I next proceeded to make appropriate suggestions to each patient. I then awakened them all, and told Z. to return the next day at the same hour. When he kept this appointment, I asked him how he was. 'I have had no paroxysm,' he answered. 'I knew I should be all right yesterday, when I left you.' Further suggestions were made that afternoon, and a fresh appointment was arranged for the morrow. At this third visit, the report was the same. The paroxysmal dypnœa was cured, and has not since returned.[1]

"We may infer that the first paroxysm was genuine, and that the 150 others were unconsciously brought on by the patient's expectation that the trouble would recur at the customary hour."

The above examples, culled from among many, of conditional spontaneous autosuggestion, will suffice to put us on our guard against pains and other symptoms which appear in us EVERY TIME that this or that happens —when the tie between the supposed cause and the sup-

[1] The report quoted in the text was penned six years after the incidents described.

posed effect is not clearly demonstrated. Attacks of migraine which a lady always has on her at home day; seizures of vertigo that come on "every morning"; toothache from which we suffer "whenever we are tired"; headaches that affect us "every time we go out of doors"; bronchitis that recurs "every winter"; the "old" rheumatism that turns up each December—these and many similar troubles are partly or wholly due to autosuggestion. The fact is proved by the prompt way in which they are cured when countersuggestion is practised after the Nancy method. Even dysmenorrhœa and other menstrual irregularities, though they are disorders of a periodic physiological function, often belong to the same category, and are frequently relieved by the same treatment.

Moreover, as we learned just now in the case of post-hypnotic suggestion, so here, we learn once more the teleology of the subconscious, which desires to justify to the subject's mind the existence of the assumed causal nexus. We find such excellent reasons for our belief. My vertigo comes on every morning because I awake feeling uneasy. My attacks recur every evening because I am worn out by the labours of the day. I have a migraine every at-home day! The matter is quite simple: there is such a crowd of people; I have to think of such a lot of things, to talk so much. Why do I always begin to vomit when the train reaches Troyes? It is natural enough, seeing that the journey from Nancy to Troyes is the maximum my stomach can endure without revolt. I ignore the fact that longer journeys on other lines cause me no inconvenience. I do not recall that I can work much harder than I work on my at-home days, and nevertheless remain entirely free from migraine; for in-

stance, at the ball the other night, although I talked a great deal there, and it was after the fatigues of the day. Everything of this kind is forgotten, repressed, censored. We hold fast to our excellent reasons. Terrible is the case of those who are unlucky enough to have a spice of intelligence, and especially of those who have medical knowledge.[1] The excellent reasons are built up into a system, whose foundations it is far from easy to undermine. If anyone wants to discuss the matter, if anyone doubts the validity of your arguments, you are annoyed, for you cling to your reasons for being ill. Or rather, your subconscious does it through your mouth, for it is the subconscious that clings to the reasons.

These reasons are like those of the young man referred to above, the man who folded his arms "because he was astonished." In reality he folded his arms because of a suggestion impressed upon his subconscious self, a suggestion that he was to assume the pose of Napoleon. Nevertheless, there were excellent reasons for his astonishment, and these reasons had their reasons in turn. The end pursued by the suggestion, exercises, as it were, a powerful magnetic attraction upon an entire chain of thoughts. We can well imagine that if, in the familiar experiment of the physical laboratory, the iron filings could speak, they too would find excellent reasons for arranging themselves in rows when subjected to the influence of the magnet!

[1] This is one of the reasons why so many doctors (even at Nancy!) still prove impermeable to the theory of autosuggestion.

CHAPTER NINE

THE ACTION OF SLEEP

The action of sleep (we mean *natural* sleep) in relation to spontaneous suggestion requires special attention, for it is of considerable value in this connection.

Many persons are quite independent of the use of alarum clocks or other means of being called in the morning. When they are going to sleep they think of the hour at which they wish to rise, and they invariably wake at the appointed time. Others attempt this plan, and fail. For everything depends upon how the "thinking" is done. This word gives us no information as to the precise condition in which those persons who succeed in waking when they desire had spontaneously placed their minds overnight. But by the use of reflective suggestion, everyone can "think" in the right manner, and can with all requisite precision repeat this elementary experiment. Furthermore, without quitting the domain of spontaneous suggestion, there are few children who have not performed this same experiment on themselves when they have gone to sleep some evening obsessed with the thought of a great joy awaiting them on the morrow (for instance, the early start for a holiday journey). A child unable to wake at eight on ordinary school days will on this occasion be wide awake at five, ready to jump out of bed. The subconscious

never sleeps, and in the subconscious the prospective joy has been at work all night.

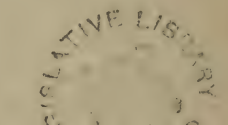
This form of suggestion may be conditional. For instance, the mother who will sleep through a thunderstorm, will awaken at her baby's least cry.

Thus, the idea we have in our minds as we fall asleep may be the starting-point of a suggestion which continues to operate during sleep. Certain dreams, certain nightmares, inspired by what we were reading before we went to bed, afford additional examples. Suggestions of this order may be realized with remarkable accuracy.

For example, as a part of some of the religions of antiquity, there was practised the art of invoking dreams which the subject ascribed to the gods, being unaware that he had caused them himself. Without dwelling upon the oracles of ancient Greece, where the priests had charms which could make the gods visible to the faithful in slumber (we verge here upon the field of hypnotic hallucination), we find in the worship of Hecate a singular example of spontaneous suggestion. After the performance of certain mysterious rites, the devotees of Hecate would have a vision of the goddess during their slumbers, provided that before going to sleep they had prayed to her in due form. They must follow the instructions of the goddess:

> My image purify, as I shall show:
> Of wild rue form the frame, and deck it o'er
> With lizards such as run about the house;
> These mix with resin, myrrh, and frankincense,
> Pound all together in the open air
> Under the crescent moon, and add this vow.

She sets forth the vow, and shows how many lizards are needed:



Take lizards many as my many forms
And do all this with care. My spacious house
With branches of self-planted laurel form.
Then to my image offer many a prayer,
And in thy sleep thou shalt behold me nigh.[1]

It is obvious that the strange and complex ritual prescribed for the preparation of the image must have favoured suggestion by making a powerful appeal to the imagination. The moon and the lizards are remarkably reminiscent of the stars and the toads in the Vaudois recipes for the charming away of warts and for the cure of dropsy.

At other times the suggestion (as in posthypnotic suggestion) has originated during sleep, in a dream, and is realized sooner or later after waking.

Here is the case of a Geneva girl whom I was treating in consultation with Pierre Bovet. She suffered from nervous troubles for which the combined action of autosuggestion and psychoanalysis seemed appropriate. She told us that in the morning she had fainted, a thing which had not happened to her for several years. Pierre Bovet then began the psychoanalytic investigation. During this, the patient recalled the fact that during the previous night she had dreamed that her father had fallen down in a fainting fit, and that this dream had made a strong impression on her mind.

Similarly, a man in perfect health dreamed that he was being operated on for appendicitis. Six months or a year later, he had an attack of this disease.

[1] Porphyry, quoted by Eusebius, Praeparatio Evangelica, Book V, Chapter XII.—The English translation is by E. H. Gifford, Eusebii Pamphili, Evangelicae Praeparationis, Oxford, 1903, Vol. III, p. 218.

It is obvious that in cases of this kind (if we assume the facts to be so accurately known that coincidence may be excluded) two alternative interpretations are possible. It may be supposed that the subconscious has intuitively grasped the imminence of certain lesions, the significance of certain organic predispositions; that it has deduced, has concluded, has revealed its conclusions, in the form of a dream. Even if this be so, it does not necessarily follow that the dream foreshadows the oncoming of an inexorable fate. It is no more than a suggestion favouring the realization of something that was perhaps threatening; but a countersuggestion may avert the trouble.

We must not suppose that what happens when we are asleep is radically different from what happens when we are awake. The foreshadowing idea, the "presentiment" that we are going to be ill, may likewise be inspired by an already existing lesion, by a predisposition to the disease. This idea is none the less a suggestion. The presentiment does not determine the future, for it may be neutralized by a countersuggestion, as we have already learned, and as we shall learn still more convincingly by and by.

Even when the subject has dreamed of events which subsequently come to pass, we must not be too ready to infer that the dream was "prophetic." Still less must we plunge into metaphysics; still less must we make the facile affirmation that absolute determinism is experimentally proved, saying that whatever is written is written. The considerations developed in Chapter VI relating to the effects of autosuggestion upon the actual course of events, will suffice to guard us against such hasty conclusions.

We have now examined:

1. The cases in which the suggestion had its origin when the subject was just falling asleep;

2. The cases in which the suggestion originated during sleep.

There are also cases of a more complex kind, more or less synthetic of 1 and 2. In these instances, the idea which is in the subject's mind just as he falls asleep, undergoes ramification during slumber; it becomes associated with other ideas requisite for its suggestive realization; during the period of sleep, and unknown to our conscious ego, complicated mental operations are performed.

For instance, we fall asleep puzzling over a sum, and wake to find it solved. The concentration of the attention before going to sleep has here determined the suggestion. Sometimes, as soon as the answer is found, it appears to the sleeper in the form of a dream, as when a number shows itself to him written on a blackboard. In other cases it wakens the subject in the middle of the night. Moreover, these occurrences are not limited to the solution of arithmetical and similar problems. A poet, unable to write an elusive stanza, will at night throw down his pen and leave the page blank. In the morning he will wake up to find the stanza ready in his mind. Sometimes, again, he will hear a voice dictating it to him while he dreams, and will awaken prematurely in order to note it down.

Finally, some question may be troubling us greatly when we go to sleep; but in the morning we find that our difficulties have vanished, and that our mind is made up. The wisdom of the nations has embodied this familiar experience in a proverb, "Night brings counsel."

These facts are well known, but we are too apt to dismiss them as exceptional or merely strange phenomena. We have failed, hitherto, to note their enormous significance, and to apply them as they might be applied.

CHAPTER TEN

THEORETICAL AND PRACTICAL CONCLUSIONS

(*The Laws of Suggestion*)

WHAT conclusions should now be drawn?

1. *Law of Concentrated Attention.*—The essential and invariable condition of spontaneous suggestion relates to the first phase of the process. *The idea which tends to realize itself in this way is always an idea on which spontaneous* ATTENTION *is concentrated,* or an idea which has been forced on the attention after the manner of an obsession. When the idea is subconscious, there is sometimes a transfer of obsession, a transfer of attention; this may at first throw us off the trail, but psychoanalysis will clear up the difficulty.

2. *Law of Auxiliary Emotion.*—As Ribot has shown, spontaneous attention is closely associated with our tendencies; it dwells on anything which is in conformity with them, or upon anything which conflicts with them; it naturally possesses, that is to say, a certain affective accompaniment. The more marked this affective accompaniment, the more strongly is suggestion favoured. *When, for one reason or another, an idea is enveloped in a powerful* EMOTION, *there is more likelihood that this idea will be suggestively realized.* In the course of the preceding examples, we have frequently seen emotion at

work. But there are typical cases in which this rôle of emotion appears in isolation, so that it is more conspicuous.[1]

We see this, for example, in stage fright, and in the terror of the examinee. A candidate who knows his subject perfectly well may suddenly be stricken with suggestive amnesia. In essence there is no difference between this and the forgetfulness of a proper name in ordinary conversation; but the examinee's amnesia is far more intense, its higher degree corresponding with the greater intensity of the emotion.

Violent emotion appears to heighten the force of suggestions of any kind. Intense fear may thus have two

[1] Fouillée, the philosopher who formulated the notion that "ideas are forces," contended for the principle that ideas act only through the instrumentality of sensibility.

Certain authors (Thorndike, for instance) have flatly denied the existence of ideomotor force. An idea as such, they say, is unable to work for its own realization; when this seems to happen, there is always an intermediary affective element. Since the pure idea is an abstraction, since in actual experience an idea invariably has an emotional colouring, it would seem a delicate matter to judge between the two theses. James Drever (Instinct in Man, A Contribution to the Psychology of Education, Cambridge University Press, 1917) opines that the decision is impracticable in the present state of our knowledge. Having deduced the consequences of Thorndike's hypothesis, he justly remarks that if it be true that there is no such thing as ideomotor force, suggestion (which is defined wholly in the terms of such a force) would no longer exist as a primary force, but would be reducible to other forces (instinct, affect, etc.). But it is obvious, as Drever himself shows, that until this reduction is possible (being assumed for the sake of argument to be possible), we must continue to look upon suggestion as a primary force. Though it may be possible that the laws of suggestion will some day be subsumed under other laws, this does not invalidate the

very different results, the divergence depending on the nature of the idea present in the mind. Fear may glue the feet to the ground. A motor dashes round the corner when you are walking in the middle of the road; you are afraid you will not be able to get out of the way in time, and consequently you cannot move a step. On the other hand, fear may restore the use of his legs to a paralytic. In 1915, in one of the air-raids on Paris, a paralyzed woman living on the fifth storey found herself in the porter's lodge on the ground floor, without knowing how she had got there; a bomb had exploded close at hand, and she had fled downstairs in a moment; the idea of flight at all hazards had seized her mind, and under the influence of the violent emotion this idea had been transformed into action.[1]

existing laws of suggestion; any more than the conception of weight is a figment because it proves to be nothing more than a particular instance of universal gravitation.

But in any case, the part played in suggestion by the affective element is considerable. Even Drever, whose views are ingenious, looks upon this affective element as a possible means for effecting the synthesis of the two meanings of the term suggestion (acceptation, and ideoreflex power). An idea, as its nature and the conditions varied, would transform itself, now into a belief, and now into an action. For like reasons, the idea would undergo transformation upon encountering in the subject, either an instinctive interest to be realized, or a deep-seated and uninhibited tendency which it could satisfy.

[Edward Lee Thorndike's book, referred to above, is Educational Psychology, briefer course, New York, 1915.—See Chapter VI.]

[1] In elucidation of this example, it is necessary to point out that in man, as in the lower animals, fear shows itself in two very different forms. In some cases fear stimulates to flight; in other cases fear stimulates to concealment and immobility.

Emotion, it might be said, instantaneously raises an idea to the boiling point, intensifies it to the degree when it can become an effective force.

3. *The Law of Reversed Effort.*—Another law we have caught a glimpse of on several occasions runs as follows: *When an idea imposes itself on the mind to such an extent as to give rise to a suggestion, all the conscious efforts which the subject makes in order to counteract this suggestion are not merely without the desired effect, but they actually run counter to the subject's conscious wishes and tend to intensify the suggestion.* The efforts are spontaneously reversed so as to reinforce the effect of the dominant idea. Whenever anyone is in the state of mind, "I should like to, but I cannot,"[1] he may wish as much as he pleases; but the harder he tries, the less he is able.

This law of reversed effort is familiar in all its simplicity to everyone who has learned to ride a bicycle. When we are at length able to wobble painfully along, should we see a big stone lying in the middle of the road, we know that all our attempts to avoid it serve only to direct our steering wheel towards the obstacle, upon which it impinges with deadly precision. Thus we seem to search out even the smallest pebbles that are most remote from our proper course. Our desperate tugs at the handlebar avail us nothing. The stone has attracted our attention, our emotions are aroused, suggestion is

Thus there are two distinct types of fear, and English authors accordingly speak of the instinct for flight and the instinct for concealment. It would be an error to assert that any kind of emotion can intensify any kind of suggestion.

[1] The condition is often expressed by the phrase, "I can't help it."

at work, and our efforts to counteract it serve merely to reinforce it.

This is something more than a quaint experience. It is an illustration of a law valid for all the obstacles we have to encounter in our path through life.

4. *Law of Subconscious Teleology.*—Suggestion acts by subconscious teleology. *When the end has been suggested, the subconscious finds means for its realization.* In the search for expedients, it often astonishes us by its skill and sagacity. All is grist which comes to its mill, and it has no scruples about cheating. Coué gives me a typical example.

A chemist's assistant, having heard talk of the results of suggestion, wished to be hypnotized by Coué, who at that date still practised this method. But the subject had an overpowering fear that it might prove impossible to reawaken him, and had continually to be reassured upon the point. Sleep was induced. At the agreed signal he opened his eyes, but declared that he was blind. Coué treated the matter lightly, hypnotized him once more, and soon put the imaginary blindness to flight. How had it originated? Under the influence of an autosuggestion, the conviction " I shall never wake again." The hynotizer's suggestion that he should open his eyes did not fully dispel this conviction. While obeying the order, the subconscious found a way to realize the primitive autosuggestion through fraud. The simulated blindness was equivalent to the closure of the eyes characteristic of sleep, which was inhibited by a countersuggestion; this false blindness was therefore chosen as the next best thing to remaining asleep.

5. In addition to the four laws hitherto formulated, we may add that spontaneous autosuggestion is a phe-

nomenon of everyday occurrence. To the subject it is no whit inferior in importance to the classic form of hypnotic suggestion. Often, indeed, the results of spontaneous autosuggestion are far more intense and far more lasting than those of hypnotic suggestion. Moreover, the state of *natural* sleep is extremely favourable to the development of spontaneous autosuggestion.

6. Having dealt with theoretical conclusions, we may now pass to practice. We should keep watch on our spontaneous autosuggestions; we should track them to their lairs; we should, as the English phrase it, "control our thoughts," checking the "undesirable" ideas which would transform themselves into noxious suggestions (ideas of weakness, poverty, impending misfortune, illness). We should abstain from attempts to learn the future by consulting mediums and clairvoyants, whose fantastic prophecies will germinate in our minds into veritable suggestions, and will tend to realize themselves, so that a prophetess of misfortune may perchance prove an unwitting criminal. When we have occasion to refer to our habitual ailments, we should be careful always to employ the *past* tense, saying "I have slept badly of late;" instead of the customary present, "I am a bad sleeper," which condenses the present and the future, and involves the future just as much as if we were to say "I shall sleep badly to-night." Furthermore we should make it a rule to talk as little as possible about our ailments.[1] When we are asked how we are, it is better to reply "Quite well, thank you"—better not only that we may avoid aggravating our own troubles, but in

[1] "The Greeks had the excellent sense not to talk overmuch about their ailments." W. H. S. Jones, Malaria, London, 1907, p. 26.

order that we may avoid disseminating suggestive contagion. Speaking generally, we should turn our minds away from "undesirable" things. But how? Here lies the field for reflective suggestion.

PART TWO

REFLECTIVE SUGGESTION

CHAPTER ONE

THE LAW OF REVERSED EFFORT

THE study of spontaneous autosuggestion has taught us that, under certain conditions, an idea is able, unaided, to release a force which, by means of subconscious activities, can realize the idea. The key of the whole mechanism is the idea itself.

We ought, then, to be able to guide autosuggestion as we please. It is a natural force which we can court. When the idea is unfavourable, we can change it; when it is good we can reinforce it. We have merely to substitute for spontaneous attention that voluntary attention with which, as civilized adults, we are all familiar. But in practice the matter is by no means simple.

Let us return to the laws which we formulated at the close of Part I. Let us consider the first three of these laws, those which relate to the preliminary conditions requisite for suggestion, those which show what characters an idea must exhibit if it is to bring about its own realization. These are:

1. The law of concentrated attention;
2. The law of auxiliary emotion;
3. The law of reversed effort.

We are tempted to say: let us conform to these laws as the mechanical inventor conforms to the laws of mechanics. Let us voluntarily place ourselves in the conditions of which nature has set us the example, by realizing them spontaneously.

But a very little thought will reveal the difficulties in our path.

In the first place, the second law reminds us that emotion plays a considerable part in the production of suggestions. We think, above all, of faith cures, of cures due to faith in the healer; and we remember that faith heals in proportion as it is an emotional state. We recall the case in which paralysis was cured by the fear resulting from an aerial bombardment. And we are forced to the conclusion that, where voluntary suggestion is concerned, this potent adjuvant, *lively emotion*, will commonly be lacking. For, while we are familiar with voluntary attention, and know it to be no less puissant than spontaneous attention, we know nothing of voluntary emotion, seeing that emotion is, by definition, a passive state which cannot be manufactured to order. Unless, indeed, we can produce it voluntarily by suggestion? But here we are running ahead, and seem to have entered a vicious circle. For the nonce we must consider the possibilities of voluntary suggestion without the help of this auxiliary on which we were relying. Happily it was no more than an auxiliary, but how valuable a one!

We are left with the first law and the third, the law of concentrated attention and the law of reversed effort. These laws, separately considered, seem to offer no further difficulties. We can concentrate voluntary attention upon any physical or mental modification we please. As for the struggle summed up in the law of reversed effort, that apparently does not come into the question at all, since here our desires are in precise conformity with our thoughts.

But we must quit generalities, and must enter the

sphere of the concrete. The frequency of spontaneous suggestions, above all of bad ones, shows us that the first task of reflective suggestion must be to neutralize these noxious suggestions, to struggle against suggestions that are already in operation. Yet now, when we concentrate voluntary attention upon the good idea which we are to substitute for the bad idea, when we devote all our energies to this substitution, what will happen? A reversal of effort, nothing more. The harder we try to think the good idea, the more violent will be the assaults of the bad idea. It will be with us as it is with the neurasthenic who engulfs his limbs in the quicksand of neurasthenia because he is struggling to escape from it (p. 43); as it is with one obsessed who aggravates his obsession by endeavouring to throw it off; as it is with the drunkard whose best efforts to give up drinking serve merely to lead him to the nearest tap-room.

Voluntary suggestion, understood as we were inclined to understand it, therefore reveals itself, not as powerless, but as possessed of negative force in its rôle of countersuggestion. Must we limit its use to cases in which we are not at war with ourselves, to cases in which we merely wish to call into existence a mental or bodily state that does not conflict with any antecedent spontaneous suggestion?

But in these cases, too, the difficulty persists. Voluntary effort essentially presupposes the idea of a resistance to be overcome.[1] It comprises both action and reaction. The two notions are simultaneously present at

[1] Cf. Maine de Biran's analysis of effort in Part I, Section II of his Essai sur les fondements de la psychologie, Oeuvres inédites, 1859, Vol. I.

the moment of the effort. If, then (and this is a matter of the first importance), I concentrate voluntary attention on an idea, which implies my making an effort, I am simultaneously conscious of an action towards this idea, and of a resistance in consequence of which the idea continually tends to escape me, so that I must unceasingly recall my wandering attention.[1] According to Maine de Biran, the consciousness of effort synthetizes that of the ego and of the non-ego. We may add that, in the effort of voluntarily attending to an idea, our consciousness embraces at one and the same time thought and non-thought; or, let us say, our state of mind synthetizes, on the one hand, the idea, and, on the other hand, the resistance which this idea has to being thought.

In these circumstances, we do not think *a single idea*, but *two conflicting ideas*. And if our state of consciousness is sufficiently reinforced by attention for the origination of a suggestion to be possible, it is not *a single suggestion* that will result, but there will be *two conflicting suggestions* which will neutralize one another more or less perfectly.[2] The yield, therefore, will be far less copious than in the case of spontaneous suggestion. And if it should unfortunately happen that the sentiment of effort and resistance predominates, we shall

[1] Attention, as Ribot has shown, is never stable. It is an unceasing return of the mind to the object of attention.

[2] Herbert Parkyn writes (op. cit., p. 96): "As a matter of fact, it is impossible to concentrate the mind upon a single object for more than a few moments at a time. Voluntary concentration really consists in a repetition of successive efforts to bring back a subject to the mind." Parkyn, however, not having grasped the law of reversed effort, fails to draw from this observation the conclusions drawn in the text.

probably arrive at a negative result, the reverse of that which we desire, a result whose dimensions will be proportional to the efforts we have made to avoid it.[1]

Experience verifies what reason has led us to forecast. Every day we see novices in the practice of reflective suggestion begin by attaining contradictory results. The indicator of the balance swings, now in the right direction and now in the wrong; and when the task before us is to uproot a preëxistent suggestion, we frequently encounter a check at the outset. At this stage, therefore, many persons, unless they find an adviser who is able to explain to them the cause of their failure, are inclined to throw the handle after the hatchet.

The unprecedented success of the New Nancy School has been due to its having had these competent advisers, persons who have been able, experimentally and by brief verbal explanations, to throw light upon the vital point, to disclose the stumbling-block, and to help people past this initial difficulty. Coué's most original contribution, his stroke of genius, was, I consider, his discovery of the law of reversed effort. He did not give it a name; he did not find for it a definitive psychological formula; he did not analyze it. But he discovered it; and, leaving to others the study of its essential principle and its innumerable consequences, he passed without delay to its most urgent applications. Adopting a practical outlook, he gave to his law an incisive formulation

[1] When we vainly endeavour to write a stanza overnight, and in the morning find the stanza ready written in the mind, it is doubtless essential that our discouragement, that the sense of impotence which led us to throw down our rebellious pen, shall not have been too vivid when we were still trying to write.

so that it could make itself felt, could be graven on everyone's memory. He is careful to point out that the mathematical terminology employed in the formula is nothing more than a metaphor "which aims at making his thought intelligible." There is no implication that the law has the theoretical precision of Weber's and Fechner's law of sensation—Fechner's statement of this law assuming definite logarithmic form. To forestall obvious criticism, it is desirable to insist upon the reservation once again. Having pointed this out, we proceed to give Coué's formula in his own words:

"When the will and the imagination are at war, the imagination *invariably* gains the day.

"In the conflict between the will and the imagination, the force of the imagination is *in direct ratio to the square of the will.*"[1]

This law of reversed effort, revealed in its full power when the subject has to strive against a prior suggestion, is not peculiar to such instances. It operates in all suggestions wherein effort of will is the leading factor. As we have just explained, it is an outcome of the very nature of effort, and it is daily verified by Coué and his followers. If we enquire of the new "pupils," of those that have failed in their first attempts, concerning the manner in which they made their suggestions, we get some such answer as this: "I took a lot of pains; I tried as hard as I could." But as soon as the pupil is made to realize that herein precisely lies his error, he promptly begins to make headway.

Coué, therefore, has the best of reasons for drawing the following conclusion:

"Above all, the will must not intervene in the practice

[1] Op. cit., p. 10.

of autosuggestion. This recommendation is absolutely essential."

And a little further on he writes:

"This observation is of capital importance. It explains why we get such unsatisfactory results, in the treatment of moral disorders, when we aim at the *reëducation of the will.* What we have to work for is the *education of the imagination.* It is thanks to this difference of method that I have often been able to attain success where others, persons of conspicuous ability, have failed."[1]

We are now able to understand how great an advance has been made from the position of Paul Emile Lévy, who looks upon autosuggestion as "the rational education of the will," and from that of Herbert Parkyn, who writes, "In developing voluntary concentration, light exercises in concentrating should be used at first, and if the practices be kept up regularly, it will become possible to impose greater and still greater tasks upon the mind."[2] It is obvious from what has been said above that in some cases autosuggestion based upon effort will have the desired result; but in many instances the result is negative, is the reverse of what we desire; and in any case it can never compete with the potency of spontaneous autosuggestion.

To sum up, autosuggestion operates in accordance with two essential laws, the law of concentrated attention, and the law of reversed effort. Now, in voluntary

[1] Op. cit., p. 10.

[2] Parkyn, op. cit., p. 95.—Consult, in addition, Bonnet, Précis d'auto-suggestion volontaire, Roussel, Paris, 1911. The subtitle of Bonnet's book is Education pratique de la volonté. This confusion is general among writers on the subject.

suggestion, these two laws are in conflict. The working of the second law tends to raze to the ground what we are building up by appealing to the first.

To secure comparatively stable results, therefore, for *voluntary* attention in the strict sense of the term we must substitute something else, which we are about to describe. But the reader will understand why we have rejected the phrase "voluntary suggestion." It involves to some extent a contradiction in terms.

Herewith we have indicated the chief innovation made by the New Nancy School, an innovation which will characterize this school and give it a definite place in history. With the law to which we have given the name of the law of reversed effort, Coué has introduced the elements of a positive revolution into the discipline of our mental activities. What we have to do, obviously, is not to *substitute* autosuggestion for the will, but to *superadd* autosuggestion to the will, as a very different mode of activity; as one which can gain desirable ends where the will fails to gain them or does so inefficiently; and as one which will only come to full fruition on condition *that it is not confused with voluntary effort.* What is the nature of this suggestion? That is the matter we have now to consider. Till to-morrow, or till a more distant future, must be left the elaboration of the manifold consequences with which the new idea is gravid.

CHAPTER TWO

THE OUTCROPPING OF THE SUBCONSCIOUS: RELAXATION

We are, therefore, faced with the following problem: *how to realize the conditions wherein the desired suggestion will come into being with the minimum of effort.* In other words, we have *to find an equivalent for voluntary attention* (in the sense in which physicists speak of the mechanical equivalent of heat), to discover a condition in which there will be no voluntary effort, or at least one in which voluntary effort will be minimal, but which will none the less be quite as competent as attention to keep our mind occupied exclusively or almost exclusively with a particular thought.

In practice, this problem was partially solved by all those who, consciously or unconsciously, were pioneers in the use of autosuggestion. They one and all refer more or less explicitly to a peculiar condition, to which various names have been given. To mention a few of these: Liébault speaks of *charms;* writers of the American and British schools, of *concentration;* Payot, the educationist, of *meditative reflection;* Paul Emile Lévy, of *collection* (recueillement); Bonnet, of *autohypnosis.*

These authors do not all refer to precisely the same condition, but in every case the state of which they speak is more or less akin to sleep. It is characterized

by complete or partial immobility, and by partial suspension of some of the mental faculties. But serious confusion arises in so far as these authors have failed to make the law of reversed effort their starting-point; and in so far as they identify the state in question with an act of will, instead of contrasting it with an act of will. Some persons are fortunate enough to grasp the essential nature of this condition, and they are successful with autosuggestion. Others, following the books or guided by the advice of authorities, taking their stand upon the will, make efforts, and achieve nothing more than debatable results. For it is just as impossible to carry out suggestion through the instrumentality of the will as it is to write poetry by the rules of prosody; just as impossible (to use Bergsonian terminology) as it is for intelligence to do the work of intuition. We are dealing with different categories.

We shall more readily grasp the affinities of the condition favourable to reflective suggestion, if we recall our knowledge of the process of suggestion in general. There are, as we have learned, three phases in suggestion: during the second of these (preëminently dynamic), work, often a vast amount of work, goes on in the *subconscious*. This subconscious or unconscious, plays a conspicuous rôle in modern psychology, which is gradually revealing its attributes. The subconscious (the term does not mean an "inferior or subordinate consciousness," but a "hidden consciousness," a consciousness that lies at a lower level than the familiar consciousness of everyday life), is comparable, to use Pierre Janet's simile, to the deeper geological strata, those covered by the superficial and only visible stratum, to which

latter our ordinary consciousness may be compared. The subconscious is a storehouse of the memories that have lapsed from the ordinary consciousness, of the wishes and sentiments that have been repressed, of the impressions of a distant past. But it is far from being inert, for it contains in addition the subsoil waters which are unceasingly at work; it contains the suggestions which will well up into the open after their hidden passage. This is all imagery, but it serves, better than pure abstractions, to convey some notion of the complex reality we have learned to recognize in the subconscious.

Now there are times when, there are states in which, these lower strata, rising as in a wave, pierce the crust and crop out on the surface, so that the superficial consciousness is more or less submerged and the subconscious becomes apparent. Sleep is the most characteristic of these conditions. Psychoanalysis has definitely proved that the subconscious is revealed in sleep; that during sleep what has been repressed rises once more to the surface and becomes manifest in the form of dreams which can be remembered in the waking state. We know, moreover, that the dream is a flow of images infinitely swifter and more copious than the flow of the waking consciousness; we know that in a minute the dream consciousness traverses scenes in which the duration of several hours is simulated. The faculties of inhibition, decision, effort, ratiocination, will, and voluntary attention, appear to be in abeyance more or less; and everything happens in the dream consciousness as if these faculties, which during the waking state slacken the mental flow, had withdrawn their restraining influence.

But, quite apart from sleep, there are fairly stable

conditions in which, though the superficial consciousness is not wholly suppressed, there is a tendency to the outcropping of the subconscious. First of all comes the state betwixt sleep and waking, just before we fall asleep, and just before we are fully reawakened. In the daytime, again, we have the various conditions usefully subsumed under the name of *reverie,* which are in fact a miniature dream, a waking sleep. In reverie we abandon the struggle for life, we cease to control our thoughts, we give them free rein; once more the repressed rises towards the surface, there are waves of sadness or desire, deceptive images surging up from the depths of our being; so closely do these resemble dream images, that psychoanalysts turn them to equal account, discovering in them the disguised and symbolical expression of everything that we refuse to avow to ourselves. To sleep, declares Bergson, is to become disinterested. In like manner, to dream is to disinterest oneself from immediate material activities; it is to disregard, for the nonce, all adaptation to everyday life, to its utilitarian solicitations; it is to set sail upon the waters of the inner world.

We may add that people vary much as to the degree in which they display a tendency to the outcropping of the subconscious. Since the condition which favours this outcropping is one of release from tension, one of *relaxation* of attention and inhibition, all the causes which predispose to such relaxation may promote the outcropping of the subconscious. Thus it is that woman, as contrasted with man, seems to be in closer and more continuous touch with the subconscious. Hartmann affirmed this many years ago in his metaphysical terminology. Ribot gives a reason for it when he shows that

the effort of attention is a muscular effort which, like all muscular effort, induces fatigue more speedily in women than in men, so that relaxation ensues earlier in the former. Still greater, in this respect, is the contrast between children and adults.

Furthermore, there are certain temperaments[1] peculiarly well equipped for communication with the subconscious; to use Flournoy's metaphor, they are "artesian wells" wherein the subsoil waters rise spontaneously to the surface.

Examples are furnished by those who display mediumistic phenomena, such as hallucinations and automatic writing, phenomena shown by psychoanalysis to belong to the domain of the subconscious. Additional instances are afforded by artists, and particularly those with true artistic genius, who feel as if their creative work were "inspired" by some other mind than their own. In most of these cases, if we subject them to psychoanalysis, we can prove that the presiding energy is that of the subconscious.[2] The revelatory character of art is doubtless in most cases due to the fact that the artist gives expression to that which everyone conceals and dissimulates—and yet to that which everyone feels the need of expressing.

We have already seen that natural sleep favours sug-

[1] Such persons are characterized by exceptional and sometimes morbid sensibility of the nervous system.

[2] Psychoanalysis has been successfully applied to art, and above all to poetry. A whole literature has sprung up dealing with this subject. Shakespeare, Leonardo da Vinci, Lenau, myths, fairy tales, etc., have been psychoanalyzed.

Consult the bibliography in Régis and Hesnard, op. cit.

gestion. But the same may be said of all the states we have just been describing, for they all have certain physiological characters which they share with sleep. They are all characterized by *relaxation*, by a *suspension of inhibition*, by an *outcropping of the subconscious*. Persons of the types mentioned in the paragraphs immediately preceding are more sensitive than others, not only to induced suggestion (this is a familiar fact), but also to spontaneous suggestion and to *reflective suggestion*. Such persons are the quickest to grasp the principles and methods of reflective suggestion, and are those who make the most rapid progress.

But, some will object, if this be so, then reflective autosuggestion is dangerous, for it requires a relaxation of the active and "higher" faculties. To practise it successfully we must model ourselves upon the weaker kinds of temperament, upon women, children, and artists. However, this objection involves a vicious circle of argument, for autosuggestion likewise is an active and creative faculty, and is in many instances more powerful than the ordinary will. You may speak of it, if you like, as a different kind of will, as a force which is latent in "weaker temperaments." There are certain persons whom we look upon as persons of "weak temperament" because they are autosuggestible and because they are continually the victims of pernicious autosuggestion. But from the day when the key to suggestion is given them, the force which was fighting against them becomes their best ally, and we see these same individuals perform prodigies of energy. A knowledge of suggestion discloses to us that in the persons in whom we had glimpsed a taint of impotence, there really exists a power with which the will we pride

ourselves on so greatly is in many instances unable to compete. Moreover, when we grasp with increasing clearness the existence of our states of relaxation and reverie, it does not follow that thereby we have enfeebled our will and reduced our power of attention. It would be as reasonable to say that sleep reduces our muscular energy when, precisely on account of the relaxation that takes place in sleep, it recuperates that energy. In a word, the will is one kind of force, and suggestion is another; their respective rôles will be explained more clearly in the sequel; but we must not suppose that in working for the acquirement of the power of autosuggestion, we are risking the loss of the power of the will, that we are throwing away the substance for the shadow. Far from it, autosuggestion, as soon as we have made it our own, will become a means for the fuller development of all our faculties, including the will.

A passing observation is requisite here. It is admitted that women, whose character is in certain respects feebler than that of men, nevertheless display at times the most marvellous endurance and energy. From this some psychologists have inferred that the "will" of women is, potentially at least if not in actual operation, superior to that of men. But when, on the other hand, we are told that effort is muscular, that the will is in large measure inhibition, and that muscular energy and the faculty of inhibition are less in women, we find ourselves involved in flagrant contradiction. This contradiction disappears if we consider the miracles of feminine energy as autosuggestive rather than as voluntary phenomena, as nervous rather than muscular; as phenomena in whose production the subconscious plays a great part—a fact which does nothing to lessen their

LEGISLATIVE LIBRARY ONTARIO

value.[1] Contrariwise, for what may we not expect when we have gained methodical control over the force which, in spontaneous action, has already worked such miracles?

In the states and temperaments we have been describing, there is usually a heightened emotional susceptibility. Reciprocally, again, it is possible that every emotion is a condition characterized by the outcropping of the subconscious, by a sort of earthquake which convulses the whole being, bringing the deeper strata to the surface. In certain emotional states the rapidity of the stream of consciousness recalls what occurs in dreams. Emotion is likewise an instigator of images,[2] a condition in which the inhibitive faculties appear to be thrown out of gear. Without embarking upon hypotheses which would for the moment be sterile, without asking whether the outcropping of the subconscious operates upon suggestion through the instrumentality of the heightened emotional susceptibility by which it is accompanied, or whether, on the contrary, the emotion operates in virtue of the outcropping which it seems to occasion; without enquiring to what extent this activity depends upon the nervous system, and what nervous or other modifications are characteristic of it—let us confine ourselves to pointing out the close relationship which exists between the two states, between, on the one hand, outcropping of the subconscious in association with increased emotional sus-

[1] By what right should muscle be regarded a priori as "superior" to nerve? The only right that occurs to me is the right of the stronger.

[2] This is especially noticeable in the poet, for the images flow from his pen more spontaneously, more vigorously, and more rapidly, in proportion as his emotion is more intense.

ceptibility, and, on the other, suggestibility (or auto-suggestibility).

Everything takes place as if suggestion, in order to bear fruit, must be buried in the subconscious; and as if this fruition were facilitated by the outcropping of the subconscious.

We are now beginning to realize in what direction we must seek the desired equivalent for voluntary attention, and the key to reflective suggestion. First of all we have to make use of, and in case of need to induce, conditions in which the outcropping of the subconscious occurs. The ways of doing this will now be considered.

CHAPTER THREE

EDUCATION OF THE OUTCROPPING:

COLLECTION

FROM what has gone before, it may at once be inferred that *the education of the outcropping* will make the soil favourable for the germination of suggestions.

Pathological or exceptional phenomena are in many instances magnifications of the normal. Now in the case of persons endowed with mediumistic faculty, in those who have the power of automatic writing for instance, there has been an education of the outcropping. The subject, by the frequent repetition of an exercise, "develops himself," thus rendering increasingly supple the mechanism by which the subconscious manifests itself. But in ordinary life, without any departure from conditions that are perfectly normal, such an education is no less possible.

At moments when we have a little leisure, when we are free from the pressing demands of outward activity, at times when we have a right to repose, let us abstain from the search for some futile distraction, let us refrain from absorbing toxins from the newspapers, and let us, instead, use our spare time for the education of the outcropping. Let us practise ourselves (nothing is easier or less tiring) in summoning the subconscious, without going to sleep, but so as to become accustomed to these

mixed states, wherein the ordinary consciousness is not completely annulled, but wherein it ceases to form a rigid cortex and becomes a transparent veil. In place of seeking repose in *distraction,* which rests the attention by changing its object, but continues to keep the attention employed, let us seek repose in *relaxation,* in which the attention no longer tries to fix itself on anything. Then the most inward, the most repressed conditions, begin to pass through the mind in the form of evanescent images of mobile and rapid reveries. This will at the same time teach us to avoid making any effort, and effortlessness is a habit we must acquire if we are to practise autosuggestion. A good way of bringing about the requisite relaxation of the mind is to immobilize the body, or, to speak more strictly, to relax the muscles, for muscular relaxation seems to generalize itself and to promote the relaxation of the muscles of attention.[1] Any kind of meditation in which we withdraw into ourselves without making too much effort to think, is a form of outcropping.

It will also be understood that when we recommend that relaxation should be substituted for distraction, we do not, in speaking of "distractions," think of those higher forms of art to which this term is often improperly applied. Etymologically, to distract signifies to draw asunder, and applied to our minds it means to

[1] When Baudouin speaks of the muscles of attention, he is thinking mainly of the optic muscles which come into play when we fix our eyes on anything to which we attend. This is based on Ribot's demonstration that the effort of attention is a muscular effort. See above, pp. 154–155. But presumably the inward faculty of attention can be "exercised" apart from any muscular training.—TRANSLATORS' NOTE.

draw the mind from one thing to another. But true art has a very different function. It helps us to live within ourselves; it helps the subconscious to rise to the surface. In the passivity, in the hypnosis (as Paul Souriau terms it), into which we are plunged by the contemplation of a masterpiece, we have perhaps the best, the most ideal example of outcropping.

Artistic education, everything which promotes the general culture of the imagination, everything which teaches us to dream, to withdraw so effectually from the outer world that it no longer seems to exist for us (but without the voluntary effort that accompanies reflection properly so called)—all these things bring about the education of the outcropping.

In the education of children, nothing could be more erroneous than to believe that in them imagination is an imperfect form of reason, so that imagination must be suppressed and must be replaced by the perfected reason. Imagination is something very different from a larval form of reason. It has its rights side by side with and independently of reason; it is a precious force for the individual, were it only as a medium for the outcropping of the subconscious and as a precondition of suggestion. We must teach children to do justice to all their faculties; they must not let any one faculty encroach; they must not, for example, allow imagination to usurp the place of reason; they must cultivate every faculty, imagination as much as the rest, nay, more than the rest. Fairy tales, which certain "positive"-minded pedants would like to proscribe, are the starting-point of artistic education, and should on no account be neglected.

The state of outcropping induced by a willed (but not

voluntary[1]) relaxation constitutes what we shall speak of as *collection* (le recueillement). At first sight there will seem to be a contradiction between these two terms, *collection* and *relaxation*, but the contradiction is apparent merely. As soon as the attention is relaxed, it becomes possible for all our inner life to flow together, to collect itself within us. Attention, if you like to phrase it thus, is dispersed over a large number of states of consciousness; but, conversely, these states are gathered together under the mind's eye, in so far as they can be gathered together. It is in this sense that we are "collected." We have gathered up our states, as the ears of corn are gathered up to form a sheaf; or rather, they have gathered themselves together into a sheaf.

Let us add, finally, that psychoanalysis, above all in the form of autopsychoanalysis, constitutes a methodical education of the outcropping, for the simple reason that it is continually calling up the subconscious. In this sense, there can be no question that the analysis of our dreams and memories by psychoanalytic methods (which cannot here be described in detail) is a most valuable habit.

But artistic education, the development of reverie, and the practice of psychoanalysis, will be greatly facilitated and reinforced by autosuggestion as soon as we know how to undertake it. Thus autosuggestion will favour the conditions which favour it in their turn, each acting and reacting on the other, accelerating their mutual progress.

Let us, therefore, practise relaxation whenever we can.

[1] This relaxation is the outcome of a decision of the will, but a decision in virtue of which the will abdicates for a season. "Relaxation" is precisely this abdication.

With habit, it will grow increasingly familiar. The subconscious will become more neighbourly, and will answer more quickly to our call, without our finding it requisite to fly to any narcotic. The habit of collection will enable us to dispense with the use of opium, of alcohol, or of the still more soothing tobacco.

To facilitate this collection, at the outset at least, we must by preference choose conditions in which we shall be disturbed as little as possible by external stimuli; we must select moments when silence prevails around us. Whenever possible, the body should be motionless, the muscles relaxed; we lie on a couch or lean back in a comfortable arm chair; we close our eyes. For *exercises* in collection these conditions are more or less optional; but they are essential when autosuggestions are to be made. Thus we shall realize the maximum of relaxation; thus we shall attain the highest possible degree of collection.

In the foregoing pages, the writer has paid his tribute to the privileged mental position of certain temperaments, women, children, and artists being typical of these. It is possible that antifeminists, pedantic pedagogues, and devotees of an overstrained "positivism," will find his remarks a trifle irritating, as invalidating some of their favourite arguments. But it is none the less true that the outcropping which is the essential characteristic of such temperaments must be cultivated by all who desire to avail themselves of the powers of well-controlled autosuggestion. If this implies a plea for nerve against the tyranny of muscle, so much the worse for those who contend that sport is the primary factor of civilization.

CHAPTER FOUR

A PSYCHOLOGICAL EQUIVALENT FOR ATTENTION: CONTENTION

COLLECTION however, with the relaxation and the outcropping which characterize it, is no more than a preliminary stage. We were in search of an equivalent for attention, and it would be remarkable were we to find this equivalent in relaxation, which is the converse of attention. We have to realize a state in which thought is sufficiently intense or sufficiently exclusive to make its power felt by the origination of a suggestion. But in the reverie which issues from relaxation, thought is scattered, mobile, and in a perpetual flux.

Now, if we are in this condition, what happens when our attention is claimed by a new stimulus, as for instance by a noise, or by some haunting thought which returns like the shooting of an intermittent pain? Something very remarkable takes place, and in current parlance we are said *to awake from our dream.* The moving swarm of mental images suddenly vanishes, as when the lighted pictures vanish from the cinematographic screen. We are confusedly aware that a moment before we were in a world abundantly stocked with mental life, but we have forgotten what was passing in that world. A few only of the more striking images continue to emerge from the void; they are fleeting outlines, disconnected and lifeless. Thus, without transitional stages,

our consciousness steps abruptly from marked expansiveness to an extreme contraction. Even the very last images of the series have almost disappeared. Their passage was doubtless too rapid, when they were no longer hemmed in by the barrier of attention; they could not fix themselves in the memory. (We know, in fact that attention is one of the conditions indispensable to memorization. When attention is relaxed, memory becomes enfeebled; when we wish to learn by heart, we must begin by attending.) On the other hand, when we "awake from our dream" we feel as if we had returned from a great distance; we are like a diver who has come back to the surface. As Bergson would phrase it, we pass from one plane of consciousness to another. We break the net of associated ideas in which we were enmeshed; and since there is now no association between the present and the immediate past, it is very difficult for the one to call up the memory of the other.

Whatever the causes of this phenomenon, we here encounter something that is comparatively rare in our mental life. Ordinarily the past prolongs itself into and merges in the present, so that we cannot grasp an isolated state of consciousness, unless we can isolate one by a somewhat violent act of attention. But here we have the impression of a mental vacuum. Nothing is present in consciousness beyond the stimulus which recalled us to ourselves, the noise, the thought, or whatever it may have been; nothing but this with its immediate associates, the cause of the noise, the memory of some particular person, or the like. Unless we violently strain our attention, the state of mind remains in comparative isolation.

The same phenomenon is still more conspicuous when

we awaken from a sound sleep. The dream upon which our mind was occupied usually lapses into complete oblivion. Yet, as everyone who has practised the analysis of his dreams is well aware, the dream was there. Auguste Forel writes: "I believe, on the other hand, that we all dream continuously when we are asleep. When I am unexpectedly aroused from sleep at any hour of the night, I can invariably seize the last broken link of a chain of dreams. But I forget it speedily unless I make a note of it or vigorously revive the memory now that I am awake."[1] So instantaneous, however, is the oncoming of oblivion, that many persons believe they have not dreamed; and the moment of waking is practically a moment of mental vacuity, when consciousness takes an entirely fresh start. It is true that in most of our reawakenings the objects which first strike our senses are familiar to us. Their associative ramifications, which we are accustomed to traverse, promptly recall us to the framework of our daily life and to the matters with which our mind was occupied the day before. But the first time we awake in a strange bed, amid unfamiliar surroundings, we are apt to be utterly bewildered. Our perceptions tell us nothing, or almost nothing. The mind remains inert, contemplating these dumb perceptions, failing to grasp the identity of things, for there are no associations to set it in motion along the timeworn

[1] Op. cit.—Here is the original German: "und glaube vielmehr, dass alle Menschen im Schlaf fortwährend träumen. Man kann mich z. B. zu keiner Nachtstunde noch so unerwartet wecken, ohne dass ich wenigstens das letzte Bruchstück einer Traumkette erwische, das ich aber sogleich wieder total vergesse, wenn ich es nicht sofort aufschreibe oder mir im Wachzustand energisch wieder vorstelle."

paths. A single mental state, or it may be a small group of mental states, rises in the mental void and seems to occupy the entire field of consciousness. The mind is like a stagnant pool; in the absence of any fresh current of images and ideas, it tends to remain stable. We are justified in describing the condition as one of mental immobility, of monoideism, one-ideadness, provided always that we are careful not to construe these terms in too absolute a sense, but merely as representing a considerable approximation to the reality.

Here we have a mental state wherein attention, with infinitesimal effort, realizes an exclusivism which, in the normal condition, can be realized solely at the cost of considerable effort. To this state, for which collection has paved the way, we may give the name of *concentration,* a term which, in the sense above defined, now forms part of the vocabulary of the subject under discussion. But if we use this word, we must define it more carefully than do the Americans, who sometimes identify concentration with close voluntary attention, and sometimes with relaxation, so that in the end the term becomes quite unmeaning. The confusion arises out of the very nature of these various conditions which border upon one another so closely, and which pass into one another by brusque transitions at times, so that at first sight it is not always easy to know with what we are dealing.

If we prefer to find another name, that of *contention* may be suggested for this peculiar form of attention, which is neither "attention" properly so called (tension towards an end), nor yet "relaxation" (in the French, "détente," i. e. the discharge or relaxation of attention). In contention, the idea is, as it were, folded back upon itself, and maintains itself in the field of consciousness

without any sensible effort on our part. In these conditions, there is spontaneously secured that *intensity* of the idea which we set out to seek. *Contention* (*concentration*) *is a psychological equivalent of attention, minus effort.*

To realize this condition, we must begin by realizing the preparatory outcropping, either by the deliberate attainment of collection or else by turning to account the spontaneous outcropping which characterizes the passage from waking to sleep and from sleep to waking. At such a time, we must, with the minimum of effort, permeate the mind with the idea of the desired modifications. Autosuggestion during the moment of first waking and during the last moments before we go to sleep is particularly valuable—the latter above all, for the machinery then set in motion has the precious assistance of slumber.

"Many of us," wrote Paul Emile Lévy a few years ago, "must have observed how favourable to the birth and ripening of new ideas is the drowsy state just before or just after sleep. We are really in a condition of slight hypnosis, but it is profound enough to be characterized by increased suggestibility. Besides, every one can judge for himself, and can push the sleep to the stage which he finds most propitious. These hours, when we are able to make use of them in such a way, are those most favourable to autosuggestion.

"After no more than a few days' practice of these exercises in slight hypnosis and autosuggestion, we note that the mind concentrates itself upon the matter with far more facility, and that, concomitantly, autosuggestion grows at once more potent and easier."[1]

[1] Op. cit.

We may add that, thanks to the law of reversed effort, it becomes more potent *because* it is easier. And the reason why it becomes easier is that the effort to think along the desired lines, which is still appreciable at the outset, becomes insignificant as soon as, by practice, we have acquired the requisite suppleness. The "muscles of attention," like all the muscles, speedily become habituated to their task.

This teaches us that if, as we have pointed out, training in relaxation is indispensable, training in effort none the less has its uses. One who has accustomed himself to making great efforts during the ordinary waking state, and more particularly one who has accustomed himself to making great efforts of attention, will find that the slight effort of contention comes much more easily to him than it comes to other people, and that for this reason contention will more speedily attain its end. It follows that the various "exercises in concentration" in the waking state, exercises recommended by American authors, are by no means devoid of value. Speaking generally, all mental or scientific work, all methodical and regular memorization, will be found excellent for training the mind to make efforts in attention, so that attention grows more and more easy. We may, therefore, follow the advice of Herbert Parkyn:

"One of the best and simplest practices for developing concentration is to read a sentence in a valuable scientific work, the subject matter of which, in itself, is absolutely unattractive, and then endeavour to reproduce the idea expressed in the sentence, either verbally or in writing, or both. Having succeeded in obtaining, memorizing, and reproducing the idea expressed in the sentence, try several sentences at a time. Next take whole paragraphs,

then pages, then chapters, and finally a whole book. There is no better exercise in memorizing and concentrating than this."[1]

It may be added that all exercises which promote muscular development in general, all those which favour the growth of muscular energy, have their uses, provided that the pupil never neglects the special training of the attention.

But the training of effort in general and of attention in particular are strongly recommended by many authorities, and therefore, without wishing to minimize their importance, we are inclined rather to lay stress upon their complements which are too often neglected. It is our task to emphasize the value of relaxation, of outcropping, of contention.

Contention (concentration) is, as it were, a crossways where two contraries meet, attention and relaxation. It simultaneously presupposes the habit of attention and that of relaxation.

Everyone, therefore, should cultivate both attention and relaxation; and each must judge for himself by personal experience whether he needs to devote peculiar care to one or the other. Most people are especially lacking in the power of relaxation; and this statement is more applicable to men than to women, to adults than to children. On the other hand, no one should neglect the training of attention; and in this case it is women rather than men, children rather than adults, in whom the faculty is deficient.

To realize contention and to render suggestion effica-

[1] Op. cit., p. 97.

cious, we shall therefore choose, by preference and on principle, the moments betwixt sleep and waking, either before or after slumber. At such times, beginners will often find that contention is weak or unstable; that the idea of physical or mental improvement, instead of remaining in the mind, is speedily dissipated. The experimenter lapses into reverie, and in an instant the vagrant mind is thinking of anything in the world except what is desired. Sleep is too close at hand, and relaxation predominates over contention. If this should happen, the subject must for a time practise collection in the fully waking state. The condition, in this case, is less profound; but the experimenter is fully conscious of what he is doing, and is therefore master of his thoughts. We should take the opportunity of suggesting to ourselves that henceforward the morning and evening suggestions will be more easily realized, and that the desired state will come into existence spontaneously. If we find, in this waking collection, that the difficulty still continues, it will be because we have not sufficiently trained our powers of attention, and in that case such exercises as those recommended by Parkyn may be of considerable value.

In general, however, we shall attain perfection if we reiterate the suggestion, making it an absolutely regular daily practice. As with all such training, muscular or mental, this regularity is the first of all essentials; and the student need not be disheartened by his clumsiness in the early stages.

For the rest, the above is a mere preliminary outline of reflective suggestion. In practice, it has to be reinforced by the simple procedures now to be described.

CHAPTER FIVE

AUTOHYPNOSIS

Outcropping, somnolence, even sleep, can be brought about by a means which we have not hitherto described, namely, by immobilization of the attention. When the attention has been immobilized for a long time upon a single object, it relaxes itself spontaneously, in part from loss of interest, and in part, doubtless, from fatigue.

In summary classification, it may be said that there are two main kinds of immobilization of the attention:

1. Fixation;
2. Seesaw.

In fixation proper, the attention is exclusively or almost exclusively occupied by a single sensation. In the case of vision, for example, this may be the contemplation of a luminous point, a vivid sensation which has an attractive influence, standing out in a privileged manner against a confused or dark background. In the case of hearing, it may be some monotonous and continuous stimulus, like the roar of a waterfall or the confused noise emanating from a great crowd.

As to immobilization by seesaw, we have examples of this in the noise of the waves beating on the shore, where two splashing sounds of different pitch answer one an-

other in an alternating song; in the tick-tack of a pendulum, where the alternation is between sound and silence; in lullabies; and in any kind of regular rhythm. As Bergson puts it, the attention "oscillates between two fixed points," between two haunting sensations continually repeated.

What happens in these cases is well known. When the attention has been held for a long time, it grows weary. In the end we can no longer see what we are looking at, we can no longer hear what we are listening to; relaxation ensues. This relaxation may pass on into sleep.

But the outcropping thus produced seems to differ to some extent from the forms of outcropping hitherto described. We are, in fact, aware that an obsessive idea or impression which is in the mind when we fall asleep, dominates the whole period of slumber. The fruitfulness of overnight suggestions proves the universal validity of this principle. We have likewise seen it unmistakably at work in the case of the sun which was unsolved when we went to sleep, and which is ready solved when we wake in the morning; and we have seen it at work in the ease with which many persons can awake at an hour dictated by autosuggestion. The method is of very wide application, as anyone can satisfy himself by the simple practice of autosuggestion, which will prove far more convincing than any theoretical demonstration. It applies, moreover, to all the states of somnolence and outcropping, just as much as to profound slumber. Consequently, the states that result from immobilization of the attention are not likely to be psychologically identical with the states of relaxation pure and simple which were given as primary examples. Experience here confirms

theory. In states resulting from immobilization of the attention, the idea of mental immobility remains dominant; from the first, we spontaneously suggest to ourselves this mental immobility. Consequently, although relaxation is in general characterized by reverie, by dispersion of mind, by mobility, in these particular instances mental immobility is readily reëstablished at the slightest solicitation, contention is favoured.

To such states of outcropping, produced by immobilization of the attention, we propose to apply the name of HYPNOSIS.

This definition of hypnosis is no more arbitrary than our definition of suggestion. It will justify itself when we come to speak of induced sleep. We shall see that the characteristic fact, in the great majority of cases universally described by the name of *hypnosis*, is the preliminary immobilization of the attention; and wherever we find this cause at work, wherever we find it leading to outcropping, we are entitled to speak of hypnosis.

Hypnosis facilitates suggestion because it favours contention.

Obviously, when autosuggestion is our aim, the hypnosis must not be pushed to the stage of profound sleep, in which we shall no longer be able to control the direction of our thoughts. But a moderate degree of hypnosis may be recommended for this purpose.

The presence of a watch or a clock not far from the ear has a lulling influence. On suitable occasions, we may take advantage of the neighbourhood of a waterfall, a stream, the seashore; or we may, in more modest fashion, turn to account the drip from a water-tap that is not perfectly closed. Or, in a dark room, we may fix the gaze on a luminous point, on the motionless flame of a night-

light, or on the flickering firelight. Everyone who has passed a vigil in a sickroom must be familiar with the hypnotic influence of the last named. Psychotherapeuts with a taste for complicated recipes tell us that a peculiarly fascinating influence is exerted by the flickering flame of a spirit-lamp when a large pinch of hemp flowers has been macerated in the spirit for twenty-four hours. For a few minutes or more we concentrate our gaze upon the flame or the luminous point, and when the eyes are tired out, we allow them to close.

It matters little what process is chosen, or what simultaneous processes are employed.[1] The value is not to be found so much in this or that recipe as in the principles of which they are the respective applications. Each one of us can think out for himself new and more practical applications, better adapted to the circumstances. The governing principle is the immobilization of the attention, either by fixation or by seesaw.

But, above all, we must be careful that the possibility of using physical adjuvants does not make us the slaves of outward circumstances. Already, indeed, we are far too much enslaved by such circumstances, thanks to the dogmas implanted in us by a short-sighted medical science from the sixteenth century down to our own day —a medical science which is ignorant of the better half of the human personality and is itself the worst of all suggestions.

Furthermore, physical procedures are not the only methods for the production of autohypnosis. The attention may be immobilized in other ways than by an outward sensation. Immobilization can be brought

[1] Vision may be monopolized by a visual stimulus while simultaneously hearing is monopolized by an auditory stimulus.

about by a mental image, by an idea. Some can send themselves to sleep by counting, or by telling their beads, this being a sort of inward lulling. The verbal images evoked in such a manner arise spontaneously, without effort, owing to the fact that we have evoked them countless times since childhood. The will is no more actively concerned than in the case of the luminous point, the flickering of the fire, or the sound of the waterfall. Attention, once directed, clings from a sort of attraction. Sometimes sleep ensues; and failing that, a certain somnolence is invariable. If we practise this method in the evening, when we are already sleepy, it is ten chances to one that the coming of sleep will be greatly favoured. If this does not happen the first time, it will happen after a few days' regular practice.

We must be careful to note that immobilization of the attention, if it is to produce its proper effect, must be carried out with no sense of strain; we must be able to maintain it with the minimum of voluntary effort. In fact, when we have to do with external sensations of the type described above (the luminous point, the waterfall, etc.), our attention is in the end held in spite of ourselves. An effort, rather, is needed to disengage it. The flame of the nightlight will have produced the requisite impression when we find ourselves contemplating it in a state of mind which we wish only to prolong. We are doubtless able to turn our eyes away, but we have no desire to do so. The condition is analogous to that in which people often find themselves on first waking in the morning; they say to themselves that they could get up if they liked, but almost against their will they continue to snuggle under the blankets. It is when this state has been attained that we may allow our eyes to close, and

may proceed to call up in the mental void the ideas which form the object of our suggestions.

In like manner, when, wishing to immobilize the attention, we employ for this purpose an internal state instead of an outward sensation, *it is essential that the attention should remain* SPONTANEOUSLY *immobilized.* This is what happens when we tell our beads or count a series of numbers, for here habit takes the place of the will, and the monotony of the internal utterance acts like the monotony of the ticking clock or the running water.

This consideration should always guide us in the search for new methods of autohypnosis.

As one of the curiosities of history, and further as a lesson in humility, we may point out that the states just described under the names of collection, contention, and autohypnosis, are described, with considerable psychological acumen though not of course in modern psychological terminology, in the precepts by which, for centuries past, the yogis of Hindustan have been accustomed to attain self-mastery.[1]

The two states whose acquirement must be the novice's first aim are known as "prâtyâhâra" (mental examination) and "dhâranâ" (concentration of the mind upon a thought).

In the precepts relative to the former state, which is preparatory to the latter, we read:

"Seat yourself for a while and allow your thought to take its own course freely. It behaves like a frisky monkey. Let the monkey jump about; wait and take note. Your thought will entertain ugly ideas, so ugly that you will be surprised. But day by day, these err-

[1] Cf. Ernest Bosc de Vèze, Traité de Yoga, Daragon, Paris, 1908.

ings will become less numerous and less extensive. During the first months you will have a thousand thoughts; then you will have no more than seven hundred; and the number will progressively diminish."

It would be difficult to give a better description of the reverie which follows relaxation, and of the rapidity of the stream of consciousness in this condition. But "wait and take note"; substitute patient exercise for voluntary effort; and contention will be born out of the scatterbrain confusion.

As for autohypnosis, we encounter it in yoga, with a mystical complexion. The sacred word AUM is repeated a myriad times, the three sounds A—U—M' being well separated, and uttered on the respective notes do—mi—sol. This, we are told, produces a mental transformation in the subject, which is preparatory to great spiritual progress.

Let us return to autohypnosis, as described earlier in our own text. Since it can be induced by immobilizing the attention on a mental state, why should we not choose, for this mental state (in preference to the bead-telling or to the counting), the very idea which is to be the object of the suggestion?

There is, in fact, no reason to the contrary, provided that the idea fulfils the requisite conditions, provided that it holds the attention rather than that the attention holds it. We must be able to think of it mechanically; ere long in spite of ourselves, as if we were obsessed by it; in the same way as that in which we listen to the sound of running water.

A very simple means of securing this is to condense the idea which is to be the object of the suggestion, to

sum it up in a brief phrase which can readily be graven on the memory, and to repeat it over and over again like a lullaby. The state of hypnosis thereupon ensues, with the effortless contention characteristic of the condition. We pass unawares into the preliminary stage of hypnosis. Relaxation occurs without our noticing it; reverie is neutralized by the presence of an idea which makes around itself a mental void. The states we have analyzed above are now synthetized into a single state which shares the characters of them all; which exhibits phases recalling now one, now another; but which differs from each. This condition is one of preëminent autosuggestibility. If we graft it upon a condition of spontaneous outcropping, as upon the morning and evening states bordering upon sleep, we shall obtain maximum results. But it may also be usefully attained during the waking hours. This method of repeating a phrase has often been recommended by American writers.

If we employ the term *contention* in the sense previously explained, we may reserve the name *concentration* for the synthetic state now described. It is superfluous to have two names for the same concept. We shall therefore define concentration as follows. *Concentration is a state of autohypnosis and of persistent contention with one idea, the autohypnosis having been induced by the lulling influence of the idea on the mind.* Moreover, this condition, like every synthesis, is far simpler in its concrete reality than it seems to be in the explanations and definitions we have to employ when we are describing it.

Let us add that, to prevent the mind from wandering, it may be well to repeat the phrase aloud, or at least to sketch its pronunciation with lips and tongue as we utter

it mentally. This motor accompaniment favours the acquirement of the habit we wish to form; gives it a certain solidity; and acts as a leash or leading string whereby, without effort, our thought is guided towards its object.

CHAPTER SIX

GENERAL RULES FOR THE PRACTICE OF AUTOSUGGESTION

We are now familiar with the practical principle upon which all reflective autosuggestion is based.[1] But when we reconsider all that we have said on the subject, it is natural that some anxiety should arise concerning the amount of time which it may be necessary to devote daily to the practice of autosuggestion. Concentration, as defined at the close of the preceding chapter, presupposes that the object of suggestion has been condensed into a brief phrase, one which the memory can retain without appreciable effort. It would seem from this as if the suggestion could apply only to a restricted object, and that a fresh "sitting" would be necessary for each particular case: one suggestion to overcome shyness; another to cure headache; another to quicken the healing of

[1] In common parlance the word "suggestion" is sometimes employed to denote the process as a whole, comprising all its three phases integrally considered; and sometimes to denote the first phase alone. Thus we are said "to suggest something to ourselves" when we propose to our mind an idea which is to act as the starting-point of a suggestion. No serious inconvenience arises from this double use of the term, for the context always makes the meaning clear. Still, when we deal with the opening phase only, it would be better to speak of "formulating" or "initiating" a suggestion. We do not actually "make" a suggestion until it is successful.

a sluggish wound; and so on. This is, indeed, the way in which most authors expound the methods of autosuggestion. We quote in full, as an example, Géraud Bonnet's prescription for the cure of stage fright.

"Let us suppose that, on some approaching day, you have to sing at a private party or on a public platform.

"You have a good voice, and you are quite familiar with what you have to sing; you know that the audience will be friendly, and that success awaits you.

"But you are panic-stricken; you feel certain that when the time comes you will be seized with stage fright.

"You are sure that you will be terrified by all the eyes that will be concentrated on you when you appear on the platform; you will become uneasy, will sing wrong notes, and will finally break down.

"This is an involuntary autosuggestion, which has taken possession of your mind.

"You can combat it by a voluntary autosuggestion.

"Isolate yourself in a room where no one will come to disturb you. To make assurance doubly sure, lock the door. Settle yourself comfortably in an armchair; or lie down, if you prefer it, on a sofa or on your bed. Close the eyes; and if you are afraid of being disturbed by some noise from outside the room, plug the ears with cotton-wool.

"Relax your body to the utmost, for this physical inertia favours mental passivity, and renders the mind more accessible to suggestion. When your nervous energy is no longer dissipated in making movements or in other work, it will be concentrated in the brain, and you will be better able to devote it to the idea you wish to realize.

"At the outset, endeavour to stop thinking altogether. Try to think of nothing at all for a time. Then direct your thoughts towards the idea which is worrying you, and counteract it by its converse, saying to yourself: 'I don't suffer from stage fright; I sing well; I am perfectly easy in my mind.'

"Take a deep breath. Wait for a moment, and then say once more: 'I don't suffer from stage fright; I sing well; I am perfectly easy in my mind.'

"Repeat the process several times; repeat it five times, ten times, or more, according to the amount of leisure at your disposal.

"Have a number of such 'sittings' every day—in bed, at night, just before you go to sleep; during the night, if you happen to be awake; in the morning before you get up, immediately after waking.

"If you carry out this plan with assurance and conviction, success is certain."[1]

Similarly, Herbert Parkyn gives us autosuggestions for success, autosuggestions for optimism, autosuggestions for the avoidance of the disagreeable consequences of winter, and so on. In themselves, all these prescriptions are excellent. But if our task must thus be approached in detail, if the sittings must be multiplied (even though, through practice, the duration of a single sitting be reduced to two or three minutes), we derive the impression that our lives will be chiefly devoted to the cultivation of autosuggestion. Above all will this be the case if the morbid symptoms, the defects, and the weaknesses we have to overcome, should assail us in great numbers. Perhaps we can keep all our suggestions for the mornings and the evenings? But then we are likely

[1] Op. cit.

to fall asleep before we have finished the series, and we shall never be up in time in the morning. Or shall we parcel out the list, getting through it by sections on successive evenings and mornings? Shall each day have its morning and its evening bill-of-fare, as at a restaurant? So be it. But now, training, the acquirement of habit by daily repetition, will go by the board. Day by day we shall need to make a new effort of thought. This unduly complicated mechanism, in a life which in any case is often far from simple, will be likely to break down before long.

Must we, then, reserve this concentration, this continued repetition of a phrase, for a small number of very special cases, while adopting a different procedure for our habitual suggestions? Such a course would seem to be indicated.

For instance, we should do well to induce the condition of autohypnosis by a physical method, or by the repetition of a phrase *integrally* summarizing the suggestions that have to be made. Having attained the requisite state, we should run the mind over the detailed list of the desired suggestions, fixing each one of them for a brief period in the centre of mental vision. And we should follow the advice of Paul Emile Lévy, who writes:

"Let us represent ourselves to ourselves, let us picture ourselves, as we would like to be—vigorous, robust, overflowing with health. The greater the sharpness of outline in this idea, the more salient it is, the more it assumes the form of an image, the better the prospects of its realization. What is well conceived will be easily realized."

This method was at first recommended by Coué. We should, he considered, formulate a general suggestion, re-

peating it to ourselves a certain number of times ("Day by day, in all respects, I get better and better"). Thence we should pass to details, dwelling mentally for a brief space upon each of the improvements specially desirable for the moment. The general formula remained the same from day to day; the details varied with passing needs.

But in the course of his long experience, Coué came across facts which led him to simplify his methods, and to lay more and more stress upon the concentration previously described.

A female patient came to consult him for troubles of trifling importance, with no thought of using suggestion for the relief of the varicose ulcers from which she likewise suffered. Coué employed in her case, as always, induced suggestion in the waking state (or in a state of slight somnolence), as will be described in Part III. He enumerated the troubles of which the patient had complained, but naturally said nothing concerning the varicose ulcers, since he was not aware of their existence. At the close of the sitting, following his usual practice, Coué impressed upon the subject the importance of practising autosuggestion every morning and every evening. After a few sittings, the patient was cured, not only of the troubles about which she had consulted the doctor, but also of the varicose ulcers, though she had given no thought to these when formulating her suggestions. Yet the ulcers had obstinately resisted various methods of treatment; and during the last few weeks before their sudden cure, no remedial cause was in operation other than the influence of suggestion.

Coué formed a hypothesis which at that time he was inclined to regard as rather improbable. During the

collective sittings the patient might have been impressed by seeing the remarkable cures that were in progress. Some of these were cases of organic disease; others were cases of nervous paralysis, and, since in the latter the cure was at times instantaneous, their effect upon the new patient's imagination was considerable. More or less unconsciously she must have formed in her mind some sort of association between these cases and the ulcers from which she herself suffered, conceiving the latter perhaps as sometimes immobilizing her legs as if she had a nervous paralysis. Under the influence of the suggestion "*In all respects,* I get better and better," her subconscious had considered the ulcers to be one of these "respects," to be a particular case embraced by the general formula.

The hypothesis seemed far-fetched. Nevertheless, Coué's attention had been directed to this line of thought. In the collective sittings, conversation between the patient and the doctor was always very brief, and a special questioning was requisite when details had to be obtained concerning this or that phenomenon. But as soon as Coué had become specially interested in this matter of unforeseen suggestions, he secured a number of reports confirming his hypothesis in the most categorical fashion possible.

Under these conditions it became superfluous for the patient to go into details when formulating suggestions. Strange as it might seem, the general formula sufficed, provided the subject's mind lingered upon the idea conveyed in the words "in all respects." Henceforward the principle of detailed suggestions was abandoned at Nancy. The above-mentioned difficulty had vanished. Every morning and every evening, the subject would

concentrate upon a general formula, as if repeating a litany. No attention to detail was needed. The simplest method proved also the most efficacious—a procedure so simple that at first scepticism naturally prevails as to its efficacy, and its full value can be realized only by those who have actually used it upon themselves.

But we must make this reservation. The great majority of those who practise this form of autosuggestion have at the outset participated in some sitting of induced suggestion where the practitioner has gone into details and has formulated suggestions applying to all the troubles of which the patient has complained. When, as in the case of the varicose ulcers, some undisclosed affection has been cured, we must doubtless admit that, in the atmosphere of the sitting and under its influence, a more or less unconscious association of ideas has been established in the mind of the subject between this particular trouble and the general form of suggestion. If the formula "in all respects" is to be truly efficacious, that formula must, it would seem, have been associated in the opening stage with all the details to which it may relate.

This implies that anyone who practises autosuggestion without having ever been subjected to induced suggestion (where the practitioner formulates details), will find it well to add something to the concentration of the morning and the evening in which he devotes himself to the general formula. In addition he should, during the day, from time to time produce a state of contention by simple collection or by autohypnosis, and should then let his mind review the detailed series of desired modifications. Only in obstinate cases will it be necessary to do this every day. But the subject will find the practice

extremely useful whenever he has a few minutes to spare.[1]

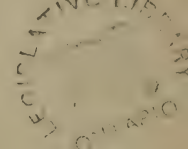
With training, the attainment of these states will become increasingly easy. After a time, the subject will find that he need merely close his eyes to secure a sufficient degree of these states.

For, as Bonnet writes: "One who is able to put himself into a more or less profound condition of autohypnotization, will soon cease to be dependent on any physical adjuvant when he wishes to enter this state and to become autosuggestible. After he has practised voluntary training for a few sittings, he will probably be able, in the fully waking state, to master his thought, to guide it, to concentrate it, to isolate himself completely from the outer world."[2]

In this manner we may isolate ourselves more or less perfectly in a tram, in a waiting-room, whenever and wherever we have nothing particular to do and we feel that boredom is imminent. Even without closing the eyes we shall be able to isolate ourselves in the street, in a crowd, during a country walk, etc. Though at first we require to be surrounded with an atmosphere of calm, this becomes less and less essential. In the end we shall find ourselves competent to isolate ourselves to some extent even in a tumultuous assembly, and when the conditions are extremely unfavourable. When a man is prey to an idea, the outer world no longer matters to him. He is in the state in which was Archimedes when he had, while in his bath, discovered his famous "hydro-

[1] As an alternative, when time and opportunity are lacking in the daytime, detailed suggestion may be practised on first waking in the morning, and general suggestion the last thing at night.

[2] Op. cit.



static principle," and in which he appeared in public having totally forgotten to put on his clothes; the state in which was Ampère when, with a piece of chalk in his hand, he would walk behind a cab chalking on the back the details of the problem with which his mind was occupied, without ever noticing that his blackboard was on the march. Such cases of spontaneous contention, and a great many others that are less picturesque, prove to us the possibility of the requisite isolation. We can produce it at will; we must learn how to do this, and how to stop the process when it threatens to become absurd or dangerous.

In a word, without making the practice of inward isolation at odd times a matter of daily obligation, without making it a task superadded to other tasks and increasing the burdens of the day, we can encourage the practice of self-isolation whenever suitable opportunities offer. However rarely we are able to do this, each time will be valuable as far as it goes. On the other hand, when we feel that, as a preliminary, we must train ourselves in exercises of attention, we shall find it well, for a time, to do these exercises regularly.

But *regularly, daily, without a single exception,* we must practise concentration in the morning and the evening. It must bear on the general and extremely simple formula ("Day by day, *in all respects,* I get better and better"). Each sitting will require a few minutes only. Through regular performance, it will become a confirmed habit, and its technique will be steadily perfected. If, even to a minimal extent, we embrace concentration and suggestion themselves within the formula "in all respects," progress will infallibly occur.

If, finally, at any time during the day, we should be seized by some physical pain or should be affected by some undesirable mental state (an obsession, a phobia, a disagreeable reminiscence or a gloomy foreboding, etc.), Coué, guided by experience, advises the following course:

Attain collection, in the best possible physical conditions, as by sitting in a comfortable armchair, motionless, with muscles relaxed and eyes closed. Localizing the suggestion, so to speak, to the matter in question, we say (inaudibly if needs must, but at least making the appropriate movements of articulation with tongue and lips) these simple words, "It is passing off," reiterating them rapidly until the trouble, if not cured, is at least sensibly relieved. A certain amount of improvement ought to be obtained in *every* case. Each time we utter the words, we shall do well to pass the hand rapidly over the affected part (the forehead when the trouble is mental). According to the magnetizers, these passes emit a healing "fluid." However this may be, the passes unquestionably aid in the fixation, the materialization, of our thoughts; like the articulatory movements, they help to sustain it, and by their monotony they tend to promote hypnotization. It is in this light that Coué regards them, and whatever may be their mode of action, their value is incontestable. Toothache or headache, however severe, a coughing fit, however violent, will almost invariably and whether passes are made or not, yield to this apparently puerile proceeding. In one experienced in the method, in a person accustomed to practise general suggestion every morning and every evening, relief will ensue within a few minutes.

But here, as always where suggestion is concerned, the finer shades are of the utmost importance. For example, success would be far more dubious were we to employ the formula "It has passed off," or "I have no pain." The trouble, being actually present, bluntly contradicts the assertion each time it is made. On the other hand, the elastic formula "It is passing off" does not arouse an internal protest. Furthermore, the words must be repeated very rapidly. "There is no harm in gabbling," Coué tells us. If between our successive affirmations, "it is passing off," we allow an interval of several seconds to elapse, there is time for us to think ten times over, "it is not passing off." In that case we may be surprised to find that the trouble is getting worse instead of better. As we are pronouncing the words, under our breath if this is necessary, but out loud if there is no hindrance to doing so, we should be carried away by the whirlwind of their speed, so that there is not a free moment for the contrary assertion. The beneficent thought must not allow the maleficent thought to get a word in edgewise.

When the pain or the undesirable mood has persisted despite our best endeavours, we should renew the special suggestion, just before we fall asleep at night, using slumber as an aid to suggestion. When we wake next morning the benefit will be plain.

In like manner, whenever we find a difficulty in going to sleep, we should let the mind be swept away, as it were, by a torrent of words, as we incessantly articulate the phrase "I am going to sleep"—having first assumed our favourite position for slumber, and having forbidden ourselves to change it on any pretext. Above all must we be careful never to allow ourselves to think

"I *want* to go to sleep." The mere fact of invoking the will suffices to prohibit sleep, and this for two reasons. In the first place, the law of reversed effort comes into operation; secondly, the essential characteristic of sleep is relaxation, and consequently sleep cannot be the outcome of an act of will, since will is a state of tension. Moreover, we must not be weary in well doing; we must not be satisfied with a couple of minutes' practice of the method, then breaking off with the naive intention of finding out whether we have gone to sleep. Naturally, we discover that we are not asleep; and, since we have deliberately put ourselves into a suggestible condition, we are now affected with a countersuggestion which nullifies the results of our previous labours.

The finer shades are of the utmost importance. Personal experience will teach us these shades, which must be felt rather than understood and explained. Early failures must be attributed to the fact that we have erred in some of the details, and we must never allow ourselves to be discouraged. After we have felt our way for a time, we shall suddenly discover one day that mastery has come to us. When a beginner complains that results are slow in their advent, Coué is fond of saying, if the patient is a woman, "Madam, if I were to put a Lebel rifle into your hands, you would probably have no idea how to use it. But this would not mean that the rifle was at fault."

The finer shades are of the utmost importance. One of Coué's supreme merits is that he has grasped this fact. A detail which proves his psychological acumen is the distinction he has established between the practice of general suggestion and the practice of special suggestion. In the case of the latter, as we have just pointed

out, he recommends that the formula should be uttered with the utmost possible speed, should be gabbled, in fact. On the other hand, the general formula for morning and evening use should, he tells us, be pronounced "piously," with all the words separately stressed, and with special attention to the phrase "in all respects." At first sight the distinction seems arbitrary. We are inclined to fancy that it is a deliberately introduced complication, intended to strike the imagination by its very illogicality, as do the bizarre prescriptions of charlatans. But this is a total misconception.

Indeed, a little thought will convince us that nothing could be more logical than Coué's advice. Though he fails to give an express reason for the distinction he draws, the reason is not far to seek. The general formula (and, above all, the phrase "in all respects") is closely associated in our mind with the idea of all the desired ameliorations. If, by a brief silence, when a state of concentration prevails, we leave the imagination free to follow up its own clues, it will probably, therefore, get to work on the list of ameliorations. Now this is just what is wanted, for thus we initiate a process which will readily be continued in the subconscious. Especially overnight, just as in the case of the arithmetical problem, do we initiate a suggestion which, during sleep, will ramify, multiply, develop the whole of its implicit content. In the intervals of silence between the repetitions of the formula, the development of the schema is set in operation. We secure the formation of a *spontaneous* procession of images. For reasons with which we are now familiar, this is preferable to a procession of images voluntarily induced; and there will be less risk that the imagination will stray from the ap-

pointed path, as it tends to do in those who are little accustomed to concentration.

When, on the other hand, special suggestion is being practised, there is no such associated train of thought, and errancy will be far more likely. Furthermore, and above all, since special suggestion is most commonly put in practice at times when the subject is actually suffering from some mental or physical trouble, there is considerable risk that the idea of this trouble may slip into any interstices in our repetition of the formula of suggestion, and may thus lead, as we have explained, to the very reverse of what is wanted.

We have dwelt upon this example to show how, in the practice of the New Nancy School, everything is based upon the most precise observation and upon the keenest psychological insight.

The foregoing analyses may have aroused in the reader's mind an impression that autosuggestion is a very complicated affair. The mechanism of autosuggestion is, indeed, complex. But the operation of this machine is simple enough, as the following summary of fundamental rules will show:

1. *Every morning and every evening, betwixt sleep and waking, practise concentration upon the formula of general suggestion.* (*"Day by day, in all respects, I get better and better."*)

2. *When, during the waking hours, you are unexpectedly assailed by some mental or physical trouble, have recourse to the particular suggestion "this is passing off." Should the trouble persist, repeat this in the evening before going to sleep.*

3. *As opportunity offers, attain the state of conten-*

tion, either through simple collection or through auto-hypnosis. Then call up as vividly as possible the image of the desired bodily and mental ameliorations.

4. *Cultivate the faculty of relaxation and the practice of collection (art, imagination, the habit of collection). Cultivate also the faculty of sustained attention (bodily and mental exercises, regular exercises in learning by heart).*

Here we have all the essentials. By adopting them we may and should attain notable results, though further advice will be given in the sequel. The most important of these four rules is the first, which must never be broken. It is the simplest as well as the most indispensable. Let us add that the student must never forget the law of reversed effort. He must invariably pay heed to Coué's advice: "Above all, be careful never to let the will intervene in the practice of autosuggestion."

It is obvious that the method here prescribed is distinguished by its extreme simplicity from other methods now in vogue.

In view of this simplicity, what estimate shall we form of other methods, for which numerous and complex procedures are requisite? How far are these procedures likely to be of any value?

Let us consider an example which may help us to answer the question. Géraud Bonnet (op. cit.), among a number of prescriptions for autosuggestion, gives the following:

"Get a transparent glass funnel holding from one to two pints.

"When all the preliminary conditions requisite for a good operation have been secured, fill the funnel almost

to the brim with some highly coloured fluid, such as red wine.

"Place the stem of the funnel in an empty bottle, having first plugged the stem with a good thickness of absorbent cotton-wool, in such a fashion that the flow is limited to a fine stream, or the fluid even emerges drop by drop only.

"With a few preliminary trials and by packing the cotton-wool more or less firmly, you will be able to arrange that the funnel will take ten minutes, fifteen minutes, or half an hour to empty itself.

"Place the apparatus on a table and sit down opposite to it, in a comfortable position, one which you will be able to retain for a long time. You may rest your hands on your knees or on the table, or you may rest your elbows on the table and your head on your hands. The bottle with the funnel should be quite near, at a distance ranging from five to fifteen inches.

"Just before you settle down, fill up the funnel, and the fluid will begin to drip into the bottle.

"Keep your gaze fixed on the upper surface of the fluid in the funnel, never permitting your attention to wander from this surface, or from the curve which represents it. Gently but continuously the level falls, and the curve which represents it insensibly diminishes, until at last it reaches the top of the cotton-wool plug and all the fluid has percolated.

"While the descent is in progress, your gaze gradually lowers moment by moment. You will feel a continuous impulse to close your eyes, but you must resist this impulse. Should it become too strong, and interfere with your sight, open the eyes very widely by lifting the upper lids.

"If, nevertheless, the uneasiness proves too much for you, desist and take a rest. Another time you will be able to continue longer; and in the end you will find yourself able to go on gazing energetically until the close of the operation, until all the liquid has percolated.

"Throughout the sitting, you must do your utmost to avoid noticing the noise which is made by the drip of the fluid into the bottle. This tends to distract your attention, and makes the exercise difficult. If it becomes too importunate, plug the ears with cotton-wool."

After detailing a number of similar exercises, Bonnet concludes as follows:

"The foregoing exercises, in which we have recourse to the sense of hearing and the sense of sight, may unexpectedly eventuate in the involuntary production of the hypnotic state.

"In fact, Braid's fundamental method for inducing hypnotization consisted in fixing the attention by the concentration of thought.

"Now in all the exercises I have been describing, and in all the analogous exercises we can imagine employing for the same purpose, these conditions are realized, or at least the subject attempts to realize them.

"It would seem, therefore, that the operation ought to terminate, or may possibly terminate, in hynotization. . . . There is no harm in that, and the prospect need not greatly disturb us. Indeed, we may rather be pleased, for we can turn it to useful account."

Let us at once point out that the author displays a certain confusion when he is speaking of these exercises. What does he propose to educate? Is it the effort of sustained attention? Or is it, on the other hand, autohypnosis? Bonnet's objective is obviously the effort

of attention. Nevertheless, if the experiment should culminate in autohypnosis (and consequently in relaxation), this matters very little and may even be advantageous. Such confusions throw the pupil off the track. They are the same as those made by the Americans in the use of the word concentration. The error, identical in all cases, lies in considering training in suggestion as training of the will. Hence the contradictions that ensue.

In practice it would be better to know precisely what is the aim of the particular exercise we are to undertake. That is why, in our opinion, the exercises must be simplified; that is why the exercises which keep the attention awake, must be sharply distinguished from those which immobilize it in order to induce hypnosis. Among the former must be classed the exercises in memorization recommended by Herbert Parkyn, and it is these which we advise for the development of sustained voluntary attention. But for the development of autohypnosis, we can use any sort of exercise in fixation. In that case, however, the more the will is in abeyance, the more rapidly is hypnosis likely to ensue.

As a general rule, therefore, let us choose simple exercise. Nevertheless, we do not underrate the occasional value of those of a somewhat complicated character, those for which comparatively elaborate preparations are needed. These seize the imagination, and often impress us in spite of ourselves, just as do old wives' prescriptions. *People are inclined to disbelieve in the efficacy of anything simple;* every doctor is well aware of this truth, and every doctor takes it into account in his advice to his patients. All the same, the retaining of complicated methods cannot be recommended except for simple-

minded persons, who would find it very difficult to understand the true mechanism of autosuggestion. The practice of elaborate exercises substitutes spontaneous suggestion for reflective suggestion, for the patient imagines that the prescription does the work, whereas the real agent is the imagination itself. It is much better to imbue our mind with the simple law which regulates autosuggestion, and to put this law into practice with equal simplicity. But routinism is so prevalent and prejudice is often so powerful that many persons find it difficult to accept the law in all its simplicity.

There is one group of exercises which requires special mention, for they have been recommended in all ages as aids to the "development of mental force." We find them already in the yoga of Hindustan, and we encounter them once more in the teaching of the ultra-modern American schools of autosuggestion. I refer to breathing exercises. Is their historical relationship to autosuggestion a mere chance, a mere matter of tradition, or has it a logical basis?

As most people know, the method consists in the daily practice of deep breathing, which may or may not be accompanied by movements of the limbs. Through training, the subject becomes capable of holding his breath for a longer time, and can maintain an interval between inspirations and expirations. It is recommended that suggestion should be practised simultaneously with the breathing exercise. We may quote Bonnet in this connection:

"Let us suppose that we wish to rid our mind of a feeling of gloom. The opposite of gloom is cheerfulness. The suggestion should bear upon the idea, 'I am cheerful.'

"The phrase is simple. Suppose we desire to use respiratory movements of average depth. The movements of inspiration and expiration have approximately the same duration and are separated by very brief intervals. During inspiration the subject thinks 'I am,' and during expiration 'cheerful.'

"Since this operation entails very little fatigue, it may be repeated as often as you like, twenty times, fifty times, a hundred times, until thought ceases, or turns to something else, or until an almost unconscious mechanism comes into play.

"Deep breathing may likewise be practised with the same associations. But here, since each phase of the complete respiration is greatly prolonged, the entire autosuggestion 'I am cheerful' may be made during inspiration and repeated during expiration. A variant would be to do nothing in the way of suggestion during the respiratory movements, and to reserve the thought 'I am cheerful' for the apparent rest which terminates and follows expiration. In this case the subject must be careful to keep his mind a blank during expiration and inspiration."

There can be no question as to the physiological value of breathing exercises. Whatever promotes bodily well-being must obviously provide a solid foundation for mental vigour, and it will consequently favour autosuggestion. But why, among the numerous methods for developing the physique, should breathing exercises have become specially associated with suggestion?

The reasons, I think, are easy to discover. In the first place the sensation of wellbeing which always follows the drawing of a deep breath, unquestionably favours the working of any ameliorative suggestion. The images

of vigour and health which we desire to evoke find a mainstay in this feeling. Furthermore, by its regular rhythm (of which the exercises make us aware), breathing exerts a stimulus analogous to that exerted by every rhythm that has a lulling influence, a stimulus which immobolizes the attention and tends to induce hypnosis. Finally, the relations between the faculty of attention and the function of breathing are well known. These considerations suffice to explain the suggestive value of respiratory exercises.

Herbert Parkyn goes further, and believes that there is a large element of suggestion in the physiological value of the much-belauded breathing exercises. If this be so, the fact does not render the value any less real. In order to obtain still better results, he recommends that respiratory exercises should be reinforced by the simultaneous practice of reflective suggestion:

"Remember to employ autosuggestion while you exercise, for you would not be taking the exercises unless you expected to accomplish something through them, and the mind is such an important factor in bringing about the results you desire, that you should direct your thoughts systematically and intelligently.

"For instance, if you are breathing to improve your general health, use autosuggestions like the following:

"The air is one of the life essentials. I am now breathing deeply and it feels so good to get this fresh air into my lungs. I know I shall feel better for it. . . . Every deep breath stimulates the heart's action and in this way assures better nutrition to every cell in the body."[1]

My chief reason for analyzing these various exercises

[1] Op. cit., 126-7.

has been my wish to show the reader how he can himself analyze the numerous exercises, respiratory and other, recommended in current manuals of autosuggestion. What these manuals chiefly lack, in most instances, is grasp of principle and knowledge of method. In the advice they give, we always find more dross than gold; there is invariably a quantity of rubbish to throw away. When any particular exercise is recommended, we must ask what useful purposes it can serve (in promoting attention, collection, autohypnosis, contention, or concentration). Relying on the general principles formulated above, we can approximately judge whether and to what extent the exercise is well adapted to attain its end.

Above all, avoid falling into a superstition about exercises; and avoid an undue multiplicity of exercises. We know that the practice of autosuggestion is simple and easy; that it need not occasion any loss of time; that everyone can and everyone should acquire the art. The morning and evening concentration is the basis of the whole thing. Exercises are no more than adjuvants, doubtless of great value. But we must be careful not to overestimate their importance.

CHAPTER SEVEN

EXAMPLES AND SPECIAL RULES

We are now acquainted with the chief rules which must be observed during the deliberate practice of autosuggestion. In addition to morning and evening concentration, we have referred to specialized suggestions which have to be formulated from time to time as need arises, and to detailed suggestions which have to be run through the mind in series as opportunity offers during the course of the day.

The practice of general suggestion is simple enough. As regards particular suggestions, on the other hand, as regards those suggestions of which general suggestion is a condensation, it will be well to enter into some detail and to deal with concrete instances.

First of all, what results are we entitled to aim at?

It may be affirmed that *reflective suggestion is of value in all domains where we have seen spontaneous suggestion at work.* In particular, since the task will often be to uproot harmful spontaneous suggestions, it is well to be aware, as a matter of principle, that *whatever suggestion has done, suggestion can undo.* This is of great value from many points of view. We have seen that in his first awkward attempts, the subject sometimes suggests to himself the very opposite of what he desires. This happens either from excess of effort, which sets the

law of reversed effort in operation; or else because, between the beneficent affirmations, silences intervene during which the converse affirmation is more or less wittingly repeated. Some readers may take fright at this warning, and may at once renounce the idea of handling so dangerous a weapon, which may explode in your face at the breech. But if whatever suggestion has done, suggestion can undo, the difficulty will be surmounted, the danger will vanish, and after a little practice the subject will be able to handle his weapon with perfect safety.

Let us add that the converse of the above principle does not hold good. It would be false to say that suggestion has been the cause of whatever suggestion can undo. We encounter various troubles, some functional and some organic, in which cures are daily effected by autosuggestion although they were in no way caused by an antecedent suggestion.

Whether the cause of the malady be or be not suggestive, the first task of reflective suggestion will obviously be to counteract the evil, regardless of its origin. But in this negative rôle of suggestion we must do our utmost to avoid using negative formulas. We must not say "this or that will not recur"; for in doing so we call up once more the idea of the trouble which is to be dispelled, and tend to impress it on the mind side by side with the idea of cure. Thus, as in the case of effort, there will arise two conflicting suggestions, which may neutralize one another more or less. We should employ by preference a positive and genuinely creative formula. The neurasthenic might say: "No longer shall I be, less and less shall I be, the victim of the gloomy thoughts, of the phobias from which I have hitherto suffered."

But he will do much better to say: "From to-day onwards, and increasingly day by day, thoughts will flow into my mind which will be unlike the old thoughts; they will not necessarily be light thoughts, unduly lively, which would do outrage to my sufferings; they will be ideas of a serious complexion, but ideas full of certitude, confidence, and hope." The tubercular patient might say: "My system is resisting the disease, the microbes are becoming less numerous every day, and are being eliminated; I am not so short of breath, sleeplessness is less persistent, the cough is not so troublesome, there is less blood in my sputum, the night sweats are less frequent and less copious;" and so on. But he will be wiser to say: "Day by day I gain strength and feel stronger; I breathe more easily, more deeply, and with greater freedom; I have better appetite, a large appetite, an irresistible appetite, and I assimilate my food perfectly; I sleep better and better, more soundly, falling asleep directly I put my head on the pillow; my slumbers are unbroken, so that even a thunderstorm cannot wake me;[1] thanks to this improved assimilation, to this sleep, to this spontaneously deep breathing, my health is being reëstablished; my blood grows richer; my white corpuscles become more numerous and are increasingly active. Each day I am capable of a little more muscular exertion, but I never overdo it; after taking exercise I find that my skin remains dry like that of a person in good health. Now I turn to the deeper cause of the trouble; this cause being attacked, the effect will disappear, and *all the symptoms, whatever their kind,* will be relieved, whether I am aware of their existence or not."

To sum up: whenever the mention of details would

[1] All these results have been obtained in tubercular patients.

involve the use of a negative formula, it will be better to rest content with a general formula. To this, therefore, we are often limited in dealing with symptoms.

In other words, if in actual fact reflective suggestion must often be negative, its mode of expression must remain as positive as possible, and the logical distinction between positive and negative suggestions may be ignored in practice. This distinction cannot provide us with a principle of classification. In the examples now to be given we shall avail ourselves of the classification we have already used in the case of spontaneous suggestions, speaking of them as representative suggestions, affective suggestions, and active or motor suggestions.

In the representative domain, every one of us should, from the first, secure appreciable results in the development of the *memory.*[1] We should never say to ourselves: "I have no memory; I am losing my memory; I have reached the age when memory begins to fail." We should affirm that our memory in general is excellent, that the special memory we are in search of is just coming back, that we shall always remember what we wish to remember without any trouble. We shall not allow a failure of memory, or two or three failures in brief succession, to disconcert us, and we shall never permit ourselves to regard them as signs that our memory is decaying. The trend of contemporary psychology is to

[1] In all the examples which follow, the reader will do well to collate them with the descriptions of the corresponding spontaneous suggestions, given in Part I, Chapters III to VIII. For the successful practice of reflective suggestion, we must call up the memory of the mental state that prevails during the initiation of the corresponding spontaneous suggestion, and must realize an analogous condition.

confirm the theory that all our memories are stored up in the subconscious, even those memories which seem to have been utterly lost. In profoundly hypnotized subjects, we are able to observe the revival, the "ecphory" (as the biologist Semon, followed by Auguste Forel, terms it), of buried memories. But that which heterosuggestion can achieve in induced sleep, autosuggestion can likewise achieve to a considerable extent.

All the *intellectual faculties* can be developed by suggestion. Let us be careful to avoid being led astray by fallacious physiological considerations. William James pointed out that the most trivial thought must affect brain structure, inasmuch as it left an imprint on the brain. *Attention,* above all, can be greatly developed and facilitated by suggestion. It is one of the conditions of suggestion, but becomes in its turn an effect of suggestion; thus an alternating cycle is set up, rendering rapid progress possible. If, at the outset, we have an unduly strong tendency towards mind-wandering, regular practice will enable us, by degrees, but easily, to correct this fault.

Nay more. In cases where, in former days, it was considered necessary to make a great effort to fix the attention, as in learning by heart and in other mental work, we now realize that better results can often be obtained by suggestion than by effort. We have seen how the subconscious can solve a problem during sleep. Let us profit by this observation. Practical experience will convince us that, by concentrating the mind on a question, we shall to a great extent spare ourselves, the effort which would otherwise have been requisite. We shall initiate subconscious activities, and the work will then go on spontaneously within us. In what cases and to

what an extent will this substitution be possible? That is a matter for the future to decide.

Artists are aware, by implication at least, that their inspirations come from the subconscious, and to evoke them they encourage conditions of outcropping. But they are apt to leave to hap and hazard the choice of the means by which these states are to be induced. Often they ascribe to the means, an importance which in reality belongs only to the resultant state—a state which might have been brought about by very different means. Hence the fetichism often displayed by artists for tobacco, alcohol, narcotics and intoxicants of all kinds, debauchery. But the desirable thing is not the alcohol, the tobacco, or the debauchery in itself; the real object of their quest is the outcropping of the subconscious which attends the intoxication. Some artists discover this, instinctively or by chance, and are thus enabled to find inspiration without the use of methods that entail physical ruin. These are the greatest of their tribe. The utilization of natural sleep, after a period of mental concentration, is peculiarly fruitful. Victor Hugo was well aware of this, and his mode of life in Guernsey has become famous. He never wrote a line in the afternoon. At this time of day he went for a drive, immersed in profound meditation. Hypnotized, as it were, by haunting thoughts, the poet would let his mind range amid his unfinished visions. Visibly cut off from his surroundings, he would hardly exchange a word with anyone. The work thus initiated went on during sleep. At five in the morning he was seated at his writing-table, ready to record upon paper the poem which was now ready in his mind.

A poet whose days were fully occupied in earning a

livelihood by prosaic means (he was a commission agent) gave me the following account of his methods of work. "The idea of a poem comes into my head: I am careful to make no attempt to write it for the moment. But after six in the evening, when I am back in my own room, I isolate myself, I plunge myself into a kind of hypnosis, I am emotionally stirred, and the condensation of the poetic images begins. I wait another twenty-four hours. On the morrow, when I have a moment to myself, I think of my poem—in the street, as I go about my business. At six o'clock, when I am once more alone in my room, my poem is ready for me, and I write it."

As far as *opinions* are concerned, the rôle of reflective suggestion must be mainly negative. It will be a self-control, a door-keeper to the mind, warding off the intrusion of ready-made opinions. It will aim at keeping reflection and judgment on the alert. It will try to save us from moral contagion, above all during epidemic seasons, during times when strong collective emotion or collective passion favours collective suggestion—as happens during revolution and in war-time, when opinions are so much influenced by suggestion that entire nations, viewed from a detached standpoint, have the aspect of gigantic lunatic asylums, so that experts have with good reason described a "belligerents' psychosis."[1] The worst feature of suggestions of this sort is that, like all suggestions, they have a teleology of their own, so that the suggested opinion generates in the subject's mind excellent reasons for its own justification. Among intellectuals, these reasons are built up into a system, which

[1] See Jacques Mesnil, Note d'un psychiatre (demain, Geneva, 1916); Auguste Forel, La psychanalyse et la guerre (Le Carmel, Geneva, 1917).

has a connected and logical semblance. Like the sufferers from major hysteria, persons holding such opinions lie in perfect good faith. A typical example is furnished by the celebrated manifesto of the ninety-three German intellectuals, issued in 1914. This and similar instances serve to show the extent to which we are all exposed to such epidemics, and how essential it is that a preventive countersuggestion should stand sentry over our judgment. In 1796, a period of intense political ferment, Goethe wrote: "Merely in order to live, I try to escape altogether from the spirit of my time."

The suggestion of representative states wherein is implicit the belief in some particular objective reality (opinions, judgments, sensations), cannot fail, from the point of view of truth, to be positively harmful. As already pointed out, if I convince myself by autosuggestion that the earth is square, it is true that I believe it, but it is not true that the earth is square. Consequently, in this domain, the rôle of suggestion must chiefly be one of countersuggestion, of prevention, of sentry duty. Unless, indeed, we are prepared to admit that certain opinions, though lacking adequate objective foundation, are none the less useful, are necessary to life, and must therefore be autosuggested. *Fiat vita, pereat veritas!* The theory has its interest, but this is not the place for its discussion. Speaking generally, it would seem that truth is a good thing, and that hallucinations and false opinions are undesirable.[1]

In the affective sphere, the rôle of suggestion must

[1] Cf. Paul Emile Lévy: "I suggest to myself that I shall have erroneous ideas. The next day I have them, and my mind is exclusively filled with them, so that I have to discontinue my work."

likewise in many cases be negative. Thus, in all varieties of physical pain, we have to employ it as an *anæsthetic*. We may lay down as a principle that it should always be possible in this manner to obtain a result, total or partial. Certain very keen or obstinate pains, such as toothache [1] and headache, are among those in which complete success may be attained in a very brief time. Having achieved relief from pain, we can then continue the use of suggestion as a preventive, so that the trouble shall not recur either on the morrow or subsequently.

Hunger is easy to control. If we are compelled to fast, we can neutralize the inconveniences of abstinence. Not only can we annul the pangs of hunger, but in addition we can minimize the accompanying symptoms of exhaustion. Should appetite be capricious, we can regulate it by the use of conditional suggestion, affirming that we shall feel hungry whenever we sit down to a meal, regardless of any stress of emotion, such as formerly would cause loss of appetite. When mealtimes come, our hunger will be irresistible, but we shall never be hungry between meals.

If we bear *cold* or *heat* badly, we can suggest to ourselves that we shall bear it better in future, and we can stress these suggestions as winter or summer draws near. We must forbid ourselves to be "afraid" of heat or cold, for to be afraid is per se a noxious suggestion.

With regard to heat and cold, we shall adopt an offensive and independent attitude; we shall no longer consider it necessary to safeguard ourselves against them by cumbersome paraphernalia. We shall be able to wear the same clothing, or nearly the same, all the year

[1] Complete anæsthesia can be secured although the caries persists.

round, and to dress lightly on the whole. This result will be secured by degrees, and will confirm us in the belief that we are far more independent of external conditions than we had fancied. The thought is in itself an excellent suggestion.

We shall master *fatigue*. In the course of hard work we shall postpone from hour to hour the onset of weariness. But we must do this *without effort*, for otherwise we should be heaping up trouble for ourselves, and in the end we should not be simply fatigued but utterly worn out. When walking we can turn to account the regular rhythm of our footsteps as a lulling influence, inducing a slight degree of hypnosis, which will facilitate the suggestion of non-fatigue. A workman engaged at a noisy machine can even use the rhythm of this machine for the same purpose, if the circumstances be such as to permit a moment's immobilization of attention.

We shall easily be able to avoid undesirable *emotions*, such as anger and fear, and also the diminutives of fear known as *phobias*, including bashfulness and stage fright. Even when we have suffered from such emotions almost ever since we can remember, we shall speedily learn how to control them. As previously indicated, the sufferer should direct his attention more especially to the movements that accompany these emotions. If we have been bashful, we shall suggest to ourselves that henceforward we shall be able to look people in the face, to speak without faltering. If we fear the dark, if we are afraid of certain animals, we shall forbid ourselves to shiver from fright at the encounter, or to make any of the other gestures of fear. If, for instance, toads are the enemy, we shall go cautiously. We shall begin by saying that next time we see a toad we shall not turn

away our eyes. On the contrary, we shall look the bugbear fearlessly in the face. When this has been successfully achieved, we shall order ourselves on the next occasion to make several steps towards the toad; to lean over it; to examine it closely. Some persons suffer from phobia of one of the domesticated animals, dogs, cats, or horses. They must set before themselves as the final goal of suggestion (a goal they must only attempt to reach by easy stages) the acquirement of a fondness for the animals which hitherto they could not endure, a pleasure in caressing these animals. When they have gone thus far—and they must persevere till then—they may feel assured that they have made a great step in self-control and a great advance in the practice of auto-suggestion.

But if there are undesirable emotions, there are also desirable emotions. We know that emotion can favour suggestion in one direction just as well as in another. While it may be difficult to arouse emotions by reflective suggestion, since an emotion must be of spontaneous origin, we can at any rate increase our emotional susceptibility, can increase it as much as we think advisable, leaving life to mould out of this plastic material the particular emotions which we have not specified in our formula of suggestion. We may, however, usefully affirm that whatever emotions we feel shall be desirable emotions.

Suggestion can play its part in regulating the whole of our affective life. To a considerable extent, we can arouse in our mind certain *sentiments,* and we can suppress other sentiments. All ethical systems, all religions, prescribe such a regulation of the affective life; but in so far as, in the attempt to carry out the prescription,

we lean on voluntary effort, we are soon convinced of our impotence, and we draw the conclusion: "This cannot be done to order."—It can, however, be done to order, but through the instrumentality of a mental attitude which is based upon suggestion and not upon the will. It is by calling up the good sentiment that we pave the way for its realization; and thereby, at the same time, we invite the bad sentiment to yield up its place. If, when we wish to expel an undesirable sentiment, we confine ourselves to the use of a negative formula, the chances are that we shall fail. *Veni Creator* is, in all respects, a far more potent exorcism than *Vade retro Satanas*. We get rid of evil by filling its place with good.

We summon joy to us; we create joy for ourselves. Goethe knew this, for he wrote: "We must laugh before we become happy; and if joy be not complaisant, we must compel her to yield." In these words, Goethe likewise reveals his realization that the expression of a sentiment calls up this sentiment. It is the counterpart of what he wrote on the same topic in *Werther*.[1]

Is there any need to dwell upon the advantage that may be derived from reflective suggestion in the mastery of our tastes, our inclinations, and our passions? "It

[1] Die Leiden des jungen Werthers, Part I, Chapter V.—Cf. Marden, op. cit., p. 141: "I know of a woman who was prone to fits of depression, of the 'blues,' who conquered them by forcing herself to sing bright, joyous songs, and to play lively, inspiring airs on the piano whenever she felt an 'attack' coming on."—Ibid., pp. 144-5: "A physician, who is a 'nerve' specialist, advises his patients to try to smile under all circumstances. . . . 'Keep on smiling, . . . just try turning up the corners of your mouth. See how it makes you feel, regardless of your mood.'"

is useless to dispute about tastes or about colours'' is a common saying. People seem to imagine that tastes, whether in food or in other things, are inalterable. But we, who have learned the part played in their formation by spontaneous suggestion, know that they are nothing of the kind. There is, in fact, no better discipline in reflective suggestion than to acquire control over all our tastes; to overcome our repulsions until we have taught ourselves to be fond of things which we could not bear to look at even in a picture; to get the better of our little weaknesses for this or that coveted dish. We ought to find no difficulty in liking everything that is edible; our stomachs would be all the better for it. If we are compelled to adopt a strict regimen (which will rarely be necessary when we know how to turn the forces of suggestion to good account), we shall learn to like what is good for us, and to have no longings for anything that will disagree with us. If we have to take a medicine with an unpleasant taste, we shall suggest to ourselves that the taste is agreeable. (In many cases, this victory over ourselves will prove much more profitable to us than the actual taking of the medicine.) In such instances, we can apply the method of special suggestion shortly before the food has to be eaten or the medicine to be swallowed. When the repulsion proves difficult to overcome, we may employ suggestion simultaneously with the taking of the dose which we find so offensive. We must close our eyes so as not to see it, and to help us to attain collection. If what we have to swallow is a draught, we shall drink it down to the accompaniment of reiterated mental affirmations that it is really quite indifferent to us. At a later stage we can teach ourselves to like it. We must not try to get on too quickly.

Passions which have struck deep root in our being are far more difficult to extirpate. I do not mean that suggestion is incompetent to conquer the greater passions. But what must be foreseen is that, after the first success, the subject will be apt to regret that his life has been narrowed. His passion has bulked so largely in his existence that, when its voice has been silenced, he finds himself in a disconcerting and distressing void. He is loath to take another step forward; and even if he should persist in formulating his suggestion, he does so with the secret wish that the suggestion may fail. A safer way is to have a better passion to substitute for the one that has proved dangerous. Still more advantageous is it to sublimate the dangerous passion, to cultivate it while transforming it. Such is the course chosen by the impassioned devotees of art, religion, and duty.

Suggestion is able to overcome the keenest mental pain. But here, too, the sufferer who has been relieved is sometimes inclined to regret the loss of his suffering. He has a sense of vacancy. Previously, his suffering was intense; he longed to be freed from it; he was single-hearted in that longing, and he cast no glance backwards. But now, after deliverance, he regrets the chains that galled him so bitterly, for their very torture made him feel alive, saved him from an emptiness which seems like non-existence. Perhaps the subject has been mourning a lost one. When his grief has been assuaged by suggestion, he feels that the dead is being robbed of the due meed of sorrow. Such a case was seen at the Nancy clinic. Of course, this remorse may be another trick of the subconscious; a new torture substituted for the old, in order to fill the void, which is the worst torture of all.

To sum up, suggestion can assuage mental pain. But is such assuagement always desirable? Here we enter upon a very different question, and it is one which lies beyond the scope of the present work.

To the active and motor sphere belong the suggestions that will be most frequently employed.

We have pointed out the part played by suggestion in the formation of habits. One of the leading rôles of reflective suggestion is the acquirement of good habits and the overcoming of bad habits. For the latter purpose, we must once more, as far as possible, use suggestion in its positive form, by suggesting a new habit to be substituted for the habit we desire to suppress. Let us quote Coué:

"To give you a clear understanding of the way in which suggestion acts in the treatment of moral defects, I will make a comparison. Let us suppose the brain to be a board into which have been driven brads representing the ideas, the habits, the instincts, which determine our actions. If we perceive that in any individual there exists a bad idea, a bad habit, a bad instinct—in a word, a bad brad, let us take another brad representing the good idea, the good habit, the good instinct; let us place its point directly over the head of the bad brad, and strike on it a single blow with a hammer; in other words, let us make a suggestion. The new brad will be driven a little way in, a millimetre perhaps, and the old one will be driven out for a corresponding distance. At each fresh blow of the hammer, at each fresh suggestion that is to say, the new brad will enter for an additional millimetre, and the bad one will emerge to the same extent. After a certain number of blows, the old brad will have

been completely dislodged, and the new one will have taken its place.''[1]

If we attack the bad habit with a negative formula, suggestion must aim at keeping the attention on the alert in case the habit should have become unconscious. For example, one who bites his nails can teach himself by suggestion to become aware of what he is doing directly he raises the fingers to the mouth. Then he can stop himself. To be sure of a successful result, he must also suggest to himself that the bad habit shall become distasteful.

When we treat a bad habit by induced suggestion, we commonly suggest to the subject that he will be totally unable to yield to his inclination. A young man of eighteen, who had been a nail-biter since early childhood, begged me to cure him by suggestion. I suggested to him that throughout the day he would be positively unable to raise his hand to his mouth. In the evening, he wished to pick one of his teeth with his finger. He was unable to do so, and had to use the point of a pencil. From this day forwards he practised autosuggestion; the habit was cured.

Impotence is not a desirable ideal to set before ourselves; nevertheless, in the cases under consideration our suggestions must take this form. We must not say: ''I shall be able to resist temptation in future.'' We must say: ''I shall no longer be tempted. Should I wish to regain a taste for my habit, I shall find that I am unable to do so.'' This form of suggestion economizes effort.

Certain habits are not fully under the control of the voluntary muscles; but the involuntary muscular movements on which they depend are perfectly amenable to

[1] Coué, op. cit., pp. 20, 21.

suggestion. This is the case with tics or habit-spasms, for instance, and with cough. In such cases we need not hesitate to suggest impotence, saying: "My tic will become less frequent; and soon, even should I wish to simulate it, I shall be unable to do so." In the case of cough, we should not say: "Henceforward I shall be able to *check* my cough." We should say: "The cough will spontaneously subside, and in a little while I shall be unable to cough however much I may try to do so; if there should be mucus in the passages which requires to be expectorated, I shall be able to expectorate it without provoking a paroxysm of cough." Such complete mastery over coughing is in most cases easy to secure, even in the advanced stages of consumption. Specialists have long since noted that certain consumptives do not cough. Since, for tubercular patients, cough is always a noxious habit, some doctors forbid their patients to cough. This is quite a mistaken prescription, unless the patient is provided with the means which will enable him to cure his cough, unless he is taught how to practise autosuggestion. Voluntary effort not to cough is an absurdity. There is a German sanatorium in which a Prussian discipline prevails. Here the rules permit the patients to cough once or twice a day; but the consumptives are punished if they cough more frequently. They make convulsive efforts to stifle the paroxysms, and these efforts are quite as exhausting as the cough. But the desired result could easily have been secured by autosuggestion.

When the habitual action is more or less pleasurable, we must not be over-sanguine as to an immediate definitive cure, above all if the habit is of long standing. Benoist-Hanappier puts the case very well when he ex-

plains that if we expect too much in these cases, we are risking a failure; and that every failure is a suggestion of impotence for the future. He writes:

"Do you crave for a cigarette? Say to yourself, 'I shall not light one for half an hour.' And keep your word. Do not attempt to go too quickly. Do not begin by saying, 'I shall wait two hours.' You would be very likely to give way to temptation before the two hours were up. This failure would discourage you, would lead you to distrust yourself, would make you lose ground. Do not imitate those who, training themselves for a long walk, suddenly double their daily distance, and overtire themselves. This is to defeat the object of training, whose method it is to enable us *without fatigue* to take longer and longer walks."[1]

We have seen how suggestion can command the events which make up our destiny, can command them through the instrumentality of the sayings and doings inspired by the subconscious. We have learned in what sense it is true that our star is within us.

O. S. Marden writes (op. cit., p. 158): "Your whole thought current must be set in the direction of your life purpose. . . . Our mental attitude, our heart's desire, is our perpetual prayer which nature answers. . . . He alone is inferior who admits inferiority, who voluntarily accepts a position of inferiority, because he thinks himself unlucky. The world belongs to him who conquers it. Good things belong to those who make them their own by the strength of their desire, by the firmness of their will."

Our only criticism of the American evangelist's pre-

[1] Benoist-Hanappier, professor at the university of Nancy, En marge de Nietzsche, Figuière, Paris, 1912.

cepts is that his use of the words "desire" and "will" betrays inadequate analysis. We may desire and will, but we shall do so vainly if we imagine or fear ourselves to be unable. Our imagination and our thought must tend in the same direction as our desire and our will. Now this depends on ourselves, on the suggestions we make to ourselves.

But it is above all in the treatment of disease that insufficient appeal has hitherto been made to the power of suggestion. For a considerable period it has been usual to employ heterosuggestion to regularize the bodily functions, to relieve constipation, to promote sleep, to cure amenorrhœa, to help digestion, to prevent nervous palpitation. This is often supposed to be the last word in psychotherapeutics. In some instances, good results have even been secured in organic disease. The general belief is, however, that, as far as organic disease is concerned success is quite exceptional. It is thought that there are, after all, not many cases for which treatment by suggestion is advisable.

This would be true if we had no resource but heterosuggestion. But autosuggestion, as we have seen, produces modifications as profound and lasting as those that have hitherto been produced by heterosuggestion. By the methodical use of autosuggestion we may hope to attain results greatly surpassing the "marvels of hypnotism." This is no mere hypothesis. Or, if it be a hypothesis, it is one which is daily being verified. The observed cures have been obtained by the regular practice of autosuggestion. It is true that the starting-point has been a heterosuggestion made by the practitioner. That is why we reserve the description of these cases for Part III, which treats of Induced Suggestion. There

we shall describe the methods employed in the Nancy clinic. But successful results are only secured *when the subject regularly practises autosuggestion.* Induced suggestion, as we shall explain, has served merely to train the patient in autosuggestion. It is to the influence of the latter that success must be ascribed.

Moreover, there are persons who, having attended a single lecture or a course of lectures, having read a well-written pamphlet, or having witnessed a sitting, have grasped the principle, have put it into practice, and thereupon (without being subjected to preliminary heterosuggestion) have secured results parallel to those we shall describe.

Everyone can verify the efficacy of the method for himself by applying it in minor troubles, thus ascertaining if he has grasped the correct procedure. You wish to stop a hæmorrhage, nose-bleeding for instance? If this nose-bleeding ordinarily lasts a quarter of an hour, with intermissions, you should readily be able to secure the formation of a good clot and the arrest of the hæmorrhage within two or three minutes. Attain collection, and make use of some form of special suggestion. You can place a watch in front of you and keep your eyes on the second-hand, having fixed a time in your mind when the bleeding is to stop. You *ought* to be successful; and if you fail, it will be because your method is still faulty, because you have overlooked some detail. In like manner, if you are subject to colds in the head which usually last a week suggest to yourself that the trouble will pass over in four days. At a later stage you can forbid the catarrh to develop at all. You can dictate to an abscess the moment when it is to burst. *Without any other treatment than* autosuggestion, you can cure

pimples, warts, varicose ulcers, eczema. The first results will encourage you, and will induce you to apply suggestion in more and more serious troubles, never allowing yourself to be discouraged by a failure. You will say to yourself that *no one knows the limit to the power of suggestion; that suggestion has cured cases supposed to be incurable;* that it must be tried in positively all cases.

The regulation of *sleep* is a most valuable exercise, for sleep is exceptionally responsive to suggestion. Since it is a relaxation, it can only be hindered, not favoured, by any *effort* to promote it. Sleep is very ready to obey suggestion. If we fail to summon sleep at will, there must be something wrong with our method. Perhaps we are making an effort at the time we formulate our suggestion. As soon as we are successful, we may be sure that we have done away with effort, and that our method is now correct.

Henceforward we shall be able to go to sleep almost instantaneously. We shall accurately prescribe the hour of waking. We shall prohibit nightmare. We shall even be able to direct the course of our dreams. We shall forbid ourselves to be awakened by any noise, however violent, unless a real danger threatens. On the other hand, we can suggest to ourselves that we shall awaken in response to stimuli which ordinarily are insufficient to rouse us; that we shall be wakened by the slightest cry of a child or by the least sound from a sick person (one who need not actually be watched, or rather one whom we can watch even when we are asleep); that we shall be awakened by a dream, by some thought that comes during sleep, in response to a question formulated overnight. In a word, nothing is more sensitive to suggestion than sleep. It is precisely for this reason that

we have to walk warily. If our method be faulty, we shall readily initiate a countersuggestion, and the result will be the very reverse of what we desire. If we suggest to ourselves that we shall sleep soundly and shall awaken at a definite time, with the half-acknowledged thought that this waking will require a continued effort of attention, our sleep is likely to be troubled, and we may repeatedly awaken before the time. But if we can suppress the half-acknowledged thought, we shall sleep soundly and shall awaken at the appointed hour, without any fatigue. It is obvious that the regulation of sleep is preëminently a matter in which attention to minor shades of detail is of the first importance. That is why it is such excellent practice to acquire the mastery of sleep. When we have done so, we can expect great things from ourselves in the way of suggestion.

For the attainment of the results above described, and of others yet more striking, it is not necessary to have been subjected to induced suggestion. An intelligent person, one able to throw off the routinist scepticism of his everyday environment, can do all that is requisite alone and unaided.

A man named Jacquemin, a chemist at Malzéville near Nancy, had suffered for a long time from chronic rheumatism. Coué, who did not know him personally, though he had treated Jacquemin's daughter, received from him one day the following letter: "I have had a wonderful success in the use of your method on myself. I suffered from rheumatic pains in the legs, so that it was difficult for me to get about. I treated myself by saying several times a day, and at night just before going to sleep: 'There is nothing the matter with me; I can walk quite well; etc.' I at once began to improve, and in a few

days I had completely recovered. I should tell you that I was theoretically convinced of the value of autosuggestion, so that this good result did not come to me as a surprise.'' The case is by no means exceptional. I have chosen it because the rapidity of the cure is peculiarly typical; and because the patient's profession is a guarantee of his power for accurate observation.

CHAPTER EIGHT

AUTOSUGGESTION AND MORAL ENERGY

From all that we have said concerning the practice of reflective suggestion, one essential idea must have emerged. It is that autosuggestion must not be confounded, as it is so often confounded, with the will. This is not merely a theoretical error, it is a practical error as well; for autosuggestion will not bear its full fruit unless it is formulated with a minimum of effort. Here we have the chief discovery of the New Nancy School.

I do not wish to imply that the earlier manuals of autosuggestion, those that have failed to grasp this principle, are for that reason devoid of value. But the most fertile pages in such books are those in which the author, breaking the rigidity of his erroneous system, resumes contact with the reality, even at the risk of self-contradiction. Bonnet, for instance, in his *Précis d'autosuggestion volontaire*, writes incidentally as follows:

"If it were not, for certain persons, an invitation to laziness, we might advise people to work little and to rest a great deal."

This is but the paradoxical expression of the truth on which we have to insist. The work of suggestion goes on *in the subconscious*, and has nothing to do with the *conscious* effort which presides over the will. We may say that suggestion is a form of will, but of *subconscious will*.

Proportionally to its results, this subconscious labour seems to induce much less fatigue than the work which is the outcome of conscious effort—unless, indeed, in the

former case, astonished by the results, we fancy ourselves to have been wearied by the stupendous task which seems to have been performed. As a general rule, suggestion appears to fatigue us no more than sleep with its dreams fatigues us. Yet sleep with its dreams represents a considerable amount of work; but work in which voluntary effort is reduced to a minimum, as in suggestion itself. This harmonizes with the teachings of contemporary physiology.

"In reflex contractures, there is no perceptible fatigue. In hysterical patients, such contractures may last for an indefinite period, without the patient being aware of any feeling of fatigue. . . . The cause of fatigue is voluntary effort, and not the mere muscular contraction."[1]

Our state of mind at the moment when we perform an autosuggested action is not a state of volition, not a state of tension. The suggested act surges up from the depths of our being, whereas the voluntary act emanates from the superficial strata of consciousness. The condition must rather be compared to what Beaunis terms "somnambulist vigil," the state in which a posthypnotic suggestion is carried out. As an exercise in autosuggestion, we may tell ourselves overnight that on the morrow, at some specified hour, we must without fail perform one or more of those trifling actions which we are apt to forget owing to their lack of interest—things which people try to remind themselves to do by tying a knot in the pocket-handkerchief—the purchase of a box of matches, the trying on of some new clothes, and the like. We shall really have succeeded in conveying the

[1] Charles Richet, Physiologie des muscles et des nerfs, Paris, 1882.

desired suggestion if, next day at the appointed hour, the idea of the proposed action suddenly comes into the mind as if someone had whispered it to us. Still better will it be if, when we are out walking, we find ourselves, *without having consciously willed it,* at the door of the right shop.

Autosuggestion, therefore, may be said to be practically at the antipodes of the ordinary will. Does this imply that it is "an invitation to laziness"; that it turns us away from healthy activity; that it slackens our energy? Nothing of the kind.

Abramowsky, head of the laboratory in the Warsaw Psychological Institute, has conducted a series of interesting experiments from which he concludes that *the energy manifested by anyone during life is in direct ratio with his power for plunging himself into a condition of autohypnosis.*[1]

In these experiments the subject has, as far as he is able, to inhibit the psychogalvanic reflex. His hand is so placed that the slightest muscular movement will lead to the passage of an electric current and the consequent deflection of a galvanometric needle. The stronger the movement, the greater the deflection of the needle. A sudden noise, such as a gunshot or a shout, or a flash of light, will arouse an emotion, and the galvanometer will measure the intensity of this emotion. In a first series of experiments, the subject is asked to yield to his impulse. In a second series, he is asked to resist, to control his emotion, to inhibit his reflex muscular response. A comparison is made between the galvanometric record in

[1] Abramowsky, Etudes expérimentales sur la volonté, Journal de psychologie normale et pathologique, 1915.

the former case and in the latter. In certain subjects, the amplitude of the deflection is always considerably less when voluntary inhibition has been at work; and we may say that in such persons inhibition has been successful, that they are really masters of themselves. Abramowsky questions them as to their mental state during the experiment, and he finds a general agreement as to the replies. The subject isolates himself in the thought of the test, in the thought of its successful performance; he makes a mental void round this idea. In a word, he is in a state of autohypnosis and concentration. Now, it appears that in ordinary life these same persons are peculiarly energetic, exceptionally gifted in respect of self-mastery.

In other subjects, on the other hand, in those who display a feebler morale in ordinary life, there is no marked difference in the amplitude of the galvanometric deflection in the two series of experiments. Nay more, *it sometimes happens that the amplitude of deflection is regularly greater in the second series of experiments than it was in the first.* Some of the subjects, therefore, do the very reverse of what they wish. Desiring to inhibit the muscular reaction, they increase it. It seems to me that Abramowsky has paid less attention to this singular fact than it deserves. The experiments ought to be repeated with the special aim of elucidating the matter. I am confident that here will be found an experimental verification of the law of reversed effort, and a way of measuring its effects. What we already know of the working of this law justifies the inference that those who came badly out of the test must have made a great effort to succeed, but must have been full of fear that they would fail.

Abramowsky's experiments are of great interest as far as they go, for they show that those who can best realize autohypnosis (the optimum condition for autosuggestion) are likewise the most energetic.

Furthermore, the same phenomenon is verified every day by persons who practise autosuggestion with intelligence.

In this connection, let me quote the autobiographical record penned by a young woman at the Fontenay aux Roses training college to whom Coué had taught autosuggestion:

"It is above all in the mental sphere that I have been able to note such marvellous results. I am now far less subject than of old to lassitude, low spirits, despondency. Sometimes these moods return, for one often cherishes gloom, though one knows it to be harmful and depressing. That is why I think it difficult to act upon oneself as far as this matter is concerned. A word from another has far more effect, and is practically indispensable.

"Turning to a different subject, I can without fatigue do twice as much work as before. During the vacation I have been able to get through two quite extensive tasks, such as a year ago I should never have attempted. This year I systematized my work, and said: 'I can do it all; what I am undertaking is materially possible, and must therefore be morally possible; consequently I ought not to experience, and shall not experience, discouragement, hesitancy, annoyance, or slackness.'

"Having thus persuaded myself, I found myself in the condition ordinarily described in the books as the outcome of suggestion, the condition in which a stronger will acts upon a weaker.

"Nothing could stop me, nothing could prevent my

doing what I had planned to do; you might almost have said that things were done by themselves, without the slightest effort on my part. If, through some accident, I was unable to get to work until a few minutes past the appointed time, I felt a discomfort which did not pass off until I could begin the allotted task. I am still quite astonished at myself. When I return to college, I shall be able to resume my studies there to the greatest possible advantage."

A few weeks later, she wrote again:

"I cannot postpone writing to you once more. I feel that I must let you know how deeply I am indebted to you. During the holidays you initiated me into the practice of your invaluable method. When I left you to come here, and to finish my studies, my rebellious memory was a trifle improved. But above all you had restored my self-confidence. You had set me free!

"I have an indomitable will, and I have hitherto succeeded in whatever I have undertaken, but at the cost of how much mental tension! I have just delivered two lectures, and much of their success is owing to you. When preparing them, I was able to retain a calmness of mind which was practically unknown to me in similar circumstances before. You have set me free in relation to myself, and you have thus enabled me to realize my life better, to make it what I wish it to be. I used often to say to myself: 'What is the use of this scholastic life, when compared with real life with its difficulties and its serious problems? Why should one bother one's head with all this bookish stuff?' And yet, I could not help worrying. Naturally, I worried the more, the more I tried not to.

"You have set me free because, despite my best efforts

(or rather, because of my efforts), I did not know how to live in the present. I was continually endeavouring to look ahead, to strain my will that I might foresee difficulties and go out to meet them. I could never think of those I love without dreading that they might be taken from me prematurely, and might die any day. I was intensely distressed at the inadequacy of my attempts to help those with whom I lived in close association. But you have given me the wisdom I lacked; or, at least, have shown me how to acquire it by degrees. I feel that I am more fully mistress of myself. Above all, I have been able to instil into two of my companions the wisdom that is so essential to a useful and harmonious existence. As for my memory, it remains untrustworthy, and rebellious at times. But I suffer less and less in this way, and I can be patient.

"Doubtless you have treated and cured cases just as serious as mine. But persons whose heart is in their work find pleasure even in small results. The least thought that they have been helpful to others entitles them to noble and pure-minded gratification. That is why I venture to trespass on your valuable time in order to express my feeling of all that I owe to you.

"P. S.—There are few Mondays and Fridays when I fail to recall your long days of devotion. You can hardly believe how greatly I am comforted and strengthened by your example."[1]

Here are some additional instances:

At Neufchâteau, Vosges, I had occasion to teach autosuggestion to two sisters, one sixteen years of age, the

[1] Letters published in the Bulletin Ecole de Nancy, 1913 and 1914.

other seven. They continued to practise the method after I had gone away, and recently I received the following letter from their mother:

"She [the elder girl] wanted to get her certificate of competence in English. I thought that the happenings of the moment[1] would weaken her resolve, or would at least induce her to postpone its execution. Nothing of the sort. We were informed that there was practically no risk in the sea passage, and she preferred to go now, rather than wait for a few months before attaining the desired end. Her courage and energy have been a great comfort to me. This is the opposite of what should have been, for she was the consoler. . . .

"As for Titite [the younger sister], on Sunday we were out walking with some friends. She was careless enough to tear her hands rather badly on a barbed wire fence. Both of them were streaming with blood. She ran back to us laughing—not a tear, not a cry. The wounds were serious enough to need a dressing which was kept on for a whole week."

These examples, especially the latter, where the subject was a little girl of only seven, show that the practice of autosuggestion, far from reducing energy, is capable of raising it to an unprecedented extent. Let me add that in the cases just recorded no special suggestion of energy had been formulated. The energy made its appearance as a natural outcome, not preconceived, not experimentally manufactured, of the actual *practice* of autosuggestion.

[1] The reference is to the war, and to the risks of crossing the Channel. The letter dates from the end of 1915.

PART THREE

INDUCED SUGGESTION

CHAPTER ONE

AUTONOMY OF THE SUBJECT

BERNHEIM has said: "There is no hypnotism, there is only suggestion." Coué would require very little persuasion to induce him to say: "There is no suggestion, there is only autosuggestion." The significance of this would be that even when the personality of a suggester may appear to substitute itself for the personality of the subject, the latter is still in reality the chief factor. The suggestion remains intra-individual.

The cases to which allusion is made in the above paragraph are, as the reader will doubtless have realized for himself, those of *profound hypnosis* or *induced sleep.*

Even in this condition, the dependence of the subject on the hypnotizer is more apparent than real. Auguste Forel insists again and again on the large share in the phenomena which must be ascribed to the personality of the subject.[1] For, in the first place, the fact that, of all sick persons, the insane are those in whom suggestion is least successful, suffices, in Forel's opinion, to prove that the core of the phenomenon remains in the mind of the hypnotized subject. Moreover, he shows how the subject completes the suggestions made to him, completes them with the aid of elements borrowed from his own personality. From this outlook, Forel considers that suggested hallucinations furnish a decisive example. In

[1] Op. cit.

fact, if to a subject in the somnambulist state we propose a negative hallucination (that is to say, if we suggest to him that he is unable to see a real object), there ensues a hiatus in his visual field, and he invariably fills in this hiatus in some way, with the aid of a positive autosuggested hallucination. In like manner, we cannot induce a positive hallucination without this involving for the subject the production of a negative autosuggested hallucination indispensable to the occurrence of the positive hallucination. Forel explains this as follows: "We cannot see a gap in the visual field without filling it in with something, be it only with a black background. Conversely, we cannot be affected with a positive hallucination unless a portion of the visual field is covered with the hallucinatory object. If the appropriate portion of the real background be not absolutely blocked out by the hallucinatory object, it is at least rendered hazy, as happens in the case of transparent hallucinations. The same thing occurs in the case of many hallucinations of hearing and of tactile sensation. . . . One who, when lying in bed, has the hallucination that he is lying on a pincushion, can no longer feel the soft mattress."

In this domain of hallucinations (always the one which seems most impressive to the onlookers), simple experiments can be devised to prove that in ultimate analysis we have to do solely with autosuggestions. The following is Coué's favourite experiment for this purpose. He suggests, for instance, to the subject an apparition clothed in white, seen on the right-hand window pane. As he makes this suggestion, he thinks of the upper pane on the right side. The subject will see the apparition on one of the right-hand panes, but it will in most cases be on the lower pane, the one through which we usually look

out. If the suggester, though he has said "right-hand pane," has wrapped tnis up in a number of details so that the right-handedness may readily be overlooked, it is quite likely that the subject will see the apparition upon a left-hand pane. As for the aspect of the apparition, each subject will describe this according to his own fancy. The experiment may be varied in countless ways. It proves beyond dispute that what is realized is not the thought of the hypnotizer. The subject has heard the latter's words, and has interpreted them as would a person in the waking state. A mental image has been called up by these words, and it is this image which transforms itself into a suggestion. He sees what he has thought, not what the hypnotizer has willed. There is no question of the conduction, as by invisible wires, of the operator's thought into the subject's brain.[1] If we may say so, the subject's own thought is conducted by the subject's own nervous system.

As a general rule it is agreed that induced sleep "increases suggestibility," this signifying that in the hypnotized state the subject obeys the operator's orders better than he would obey them in the waking state; that suggestions proposed by the operator, whatever these suggestions may be, have more chance of being realized than if they were proposed to the subject in the waking state. But nothing is more liable to variation. Every practitioner has come across subjects who are less obedient in induced sleep than they are in the waking state. Those even who are most docile in the hypnotic state, none the less quite unexpectedly impose a plea of excep-

[1] The question of telepathy involves very different considerations. This problem is not raised by the ordinary manifestations of hypnotism.

tion to certain suggestions. These facts, ostensibly contradictory, are perfectly explicable on a theory of autosuggestion. Indeed, on such a theory, it is the contrary which would surprise us. The operator's suggestion can be realized solely on condition that it is accepted by the subject's mind and transformed into an autosuggestion.

Now what does this *acceptation* involve? The question is far from simple. We may say that the acceptation is not a conscious and deliberate act of will. It would be better to compare the subject's mind to a soil which may be sometimes suitable and sometimes unsuitable for the implanting of the seed of suggestion sown by the operator. In most instances, the soil has been prepared by an earlier spontaneous autosuggestion. If the subject allows himself to be hypnotized with the preconceived idea that, though he will go to sleep, the operator will be able to do nothing with him, the probable result will be (since, by a law with which we are perfectly familiar, this idea dominates his mind throughout the induced sleep) that the suggestions proposed to him will fail to take effect. Especially will this failure ensue when the subject is extremely suggestible, for then the idea which was in his mind when he was hypnotized will infallibly dominate him. On the other hand, it has often been noted that those who were absolute sceptics before they were hypnotized, those who did not even believe in the reality of the hypnotic sleep, are sometimes exceptionally docile in the hands of the hypnotizer. We might even contend that when it has proved possible to hypnotize a sceptic, this sceptic will then be an excellent subject. The very fact of feeling sleep take possession of him has abruptly refuted his scepticism. He has been alarmed at finding his freewill escaping him—above all

if there has been a wager, and if his vanity is also at stake. It would seem that from the first onset of the symptoms of hypnosis (indistinctness of vision, sense of weight in the eyelids), such persons are seized with alarm. This emotion hastens the onset of sleep, and all the more when the subject makes adverse voluntary efforts, for these efforts are promptly reversed. Those who fancy beforehand, without always acknowledging it to themselves, that they will become mere puppets of which the hypnotizer will pull the strings, those who tremble at the thought of what they will become, are very likely to become what they dread. Such, it would seem, are the only cases in which this puppetdom actually arises. It is not a phenomenon of hypnotism, but of autosuggestion. It is not a characteristic of profound hypnosis.

When a subject who is customarily docile opposes a plea of exception to some particular suggestion, we must not attempt to explain this refusal as a deliberate exercise of will. The question is always one of the soil on which the seed has fallen. We shall find, on close examination, that the suggestion has involved some infraction of the subject's deeply-rooted tendencies, that it conflicts with his character, with his inveterate habits. If, for instance, we propose some bad action to a good man, conveying it in the form of a posthypnotic suggestion, at the appointed time the idea of performing this action will come into his mind, but he will probably have no difficulty in rejecting the prompting, just as he habitually represses other bad ideas that arise in his mind from time to time.

Speaking generally, indifferent suggestions, and those which the subject knows to be useful to him, are ac-

cepted; repugnant suggestions are spontaneously rejected. This seems to be the rule.

We must add that a very important element in this connection is the affective relationship between the subject and the operator. The subject will more readily accept suggestions from a person whom he loves, or from one in whom he has perfect confidence. Fear, like fondness, may lead to results; but these results commonly lack uniformity and are apt to be unstable.

In any case it is undesirable that the subject should become a puppet in the hands of the operator, or should imagine that he must become a puppet. Those who witness certain hypnotic séances (real or simulated) cannot fail to be struck with the precision with which certain suggestions are carried out, and the idea of the subject's absolute dependence then germinates in the mind. Or a person may have listened to an account of the "marvels of hypnotism," may have read newspaper articles or trivial stories in which the hypnotist has been represented as all-powerful. If such a person subsequently allows himself to be hypnotized, he may exhibit a state of absolute dependence; but the dependence is an autosuggestion, the outcome of a superstition about hypnotism.

The question is often mooted, "Can persons be constrained by hypnotism to the performance of a bad action?" From what has been said above, it will be obvious that in the writer's opinion the correct answer is, "Yes, if the subject imagines this to be possible." It is, therefore, of considerable importance that the superstition should be destroyed. Books that point out the dangers of hypnotism are far more dangerous than hypnotism itself.

For us, heterosuggestion, even during induced sleep, is still an autosuggestion. But we must not be interpreted as implying that this autosuggestion is an act of will on the subject's part. By now the reader will know enough about autosuggestion to realize that the imagination from which it arises is as far as possible removed from the will.

If autosuggestion be the only force at work even in induced suggestion, there follows a practical consequence of the utmost importance. Induced suggestion must not be performed by the operator for its own sake; he must regard it as *the education of the subject's power of autosuggestion.* For though the practitioner may secure brilliant or strange results by heterosuggestion, we find, whenever we probe the matter to the bottom, that he has done nothing more than liberate the subject's autosuggestions. If, however, the practitioner does not give the subject the key to autosuggestion, the latter will believe that the former's influence is the cause of everything, and the results will be apt to prove extremely fugitive. When left to himself, the subject will find that these results tend gradually to disappear. This happens all the more when, during the induced sleep, strange phenomena have occurred. In reality the phenomena of heterosuggestion are less remarkable than many spontaneous autosuggestions, but the subject ignores these latter. On the other hand, the hypnotic phenomena which he has seen produced in others and which he knows to have been produced in himself, reveal the laws of suggestion by isolating them in a way which cannot fail to strike the imagination. In like manner, electricity is now everywhere at work, and is taken as a matter of

course; but the first time a child is shown electrical experiments in the physical laboratory he feels that he is witnessing marvels. Our subject, then, believes that the hypnotizer is endowed with wonderful powers. To these powers he attributes the result, and imagines that in the absence of the cause (the hypnotizer) there can be no effect. This partly explains why profound hypnosis, in which suggestibility is apparently increased, has less marked and less lasting results than spontaneous suggestion.

There are additional reasons for dispensing as far as possible with the use of induced sleep as a general method of treatment. When we attempt to hypnotize a new patient, we rarely find that profound hypnosis, the genuine induced sleep with amnesia after waking, can be brought about on the first occasion. In many subjects, it is never perfectly attained during the whole course of treatment.[1] As a rule, we shall bring about slight or medium hypnosis (somnolence, hypotaxia); and when this has passed off the subject will remember everything that has been said and done. More or less consciously, he will then be apt to reason as follows: "The doctor was not able to put me to sleep; but he wanted to send me to sleep in order that he might cure me; therefore he will not be able to cure me." This autosuggestion becomes firmly fixed in the patient's mind, and partly or wholly

[1] I have seen a number of Bernheim's old patients. Most of them said: "I never went to sleep at all"; or, "I was still wide awake in the hypnotic sleep"; or, "I slept without sleeping"; or, "I am not sure if I was really asleep"; or, "To please him, I told him I had been asleep."—As regards the last phrase, we know that this is generally an illusion on the part of the subject; but its existence shows that the sleep, though real, was not very profound.

neutralizes the good effects of the treatment. Perhaps the practitioner will take the precaution of telling the patient that profound sleep is not necessary. But if, none the less, the practitioner makes use of methods which aim at inducing as profound a sleep as possible, if he sends all his patients to sleep in so far as he is able to do so, the subject will be likely to say to himself that somnolence is a mere makeshift, that profound hypnosis is what really counts, and that in its absence the results will be unsatisfactory.

On the other hand, when profound hypnosis ensues, the subject has no remembrance of the condition; and when we tell him to make autosuggestions through inducing an analogous condition for himself, the advice is a dead letter. Profound hypnosis, therefore, is not our ideal, when our aim is to educate autosuggestion.

These considerations, the fruit of clinical experience, and confirmed by time, have led Coué to abandon profound hypnosis as part of a general curative system. His method is now wholly based upon slight hypnosis, so slight that it can hardly be distinguished from the waking state. In the great majority of instances the method gives better results than one wholly based upon profound hypnosis. If, in exceptional cases, the induction of profound hypnosis seems indicated, it should not be exclusively employed, but should be alternated with slight hypnosis, for in the latter condition we can educate autosuggestion by making suggestions to the subject in the waking state.

This evolution of the method, which has culminated in the abandonment of profound hypnosis for all but exceptional cases, must not be identified with a parallel development realized by Dubois and Déjerine. Accord-

ing to these authors, hypnotism must be abandoned. Suggestion is to be replaced by "persuasion." The reader might suppose the distinction to be purely verbal, but there is more at stake. Dubois[1] and Déjerine[2] claim to address persuasion to the subject's *will* and *intelligence*, to his superficial consciousness. Suggestion, in their view, is dangerous, because it addresses itself to the subconscious, because it tends to be "an education in automatism." What their movement has in common with the New Nancy School is that it proposes to render the subject both master and author of his own betterment, to make him more independent of the practitioner. In this aim we are at one with Dubois and Déjerine. But the means they would employ for its attainment shows that their psychology is at fault. We are controlled by the subconscious. The fact is proved by the phenomena of spontaneous suggestion. It is impossible for us, in our turn, to exercise any control over the activities of the subconscious unless we enter into relations with it. Coué's autosuggestion is a means for opening up relationships of this kind; Dubois' and Déjerine's persuasion is not. In earlier pages I referred to the well-known powerlessness of reason and will in the struggle against passion. "Persuasion" can make its way no further than into the superficial strata of the mind. It does not bore deep enough to tap the subsoil waters, and yet its advocates claim that it can provide us with refreshing draughts. It is undeniable that Dubois and Déjerine have secured excellent results in

[1] Dubois, Les psychonévroses et leur traitement, Masson, Paris, 1904.

[2] Déjerine, Les manifestations fonctionelles des psychonévroses. Leur traitement par la psychothérapie, Masson, Paris, 1911.

actual practice; but their successes doubtless depend upon their personality, their sincerity, their devotion, which have awakened confidence in their patients and have initiated beneficial autosuggestions in the minds of these. Here, the *intelligence* plays no more than a secondary part. As for the *will*, the appeal to this faculty, as we have shown, is a disastrous error. Finally, the method of "persuasion," even in the view of its founders, has a very limited field of application when compared with the method of autosuggestion as perfected by the New Nancy School.

CHAPTER TWO

PRELIMINARY EXERCISES

THE first step in the subject's autosuggestive education is to show him, by simple experiments, how readily an idea can realize itself, provided that it exclusively occupies the mind. The subject will first see these experiments performed by others. In the next stage he will do them himself, and thus, from being mere *experiments*, they will become *exercises*.

The series of elementary exercises which I now consider most valuable, so that I have come to make a methodical use of them whereas at first I regarded them as no more than supplementary illustrations, are carried out with the aid of *Chevreul's pendulum*.

These experiments with Chevreul's pendulum occupy, in the theory of autosuggestion, the place occupied in electrical theory by the electrical pendulum—the ball of pith suspended by a silk thread. It is merely requisite to explain to the pupil that the more complex and more important phenomena of autosuggestion are no more than applications of the principle deducible from the working of Chevreul's pendulum.[1] This will enable him to grasp the whole bearing of the principle in question.

[1] M. E. Chevreul, op. cit.—In 1830 this distinguished chemist became director of the Natural History Museum in Paris. Born 1786, died 1889. Perhaps the only man of world-wide fame whose centenary has been celebrated during his lifetime.—TRANSLATORS' NOTE.

Chevreul, it will be remembered, had had his interest awakened by the "exploratory pendulum" used in his day by clairvoyants and in drawing-room séances. This pendulum, held in the medium's hand, consisted of a ring suspended by a hair. The ring hung down into a tumbler or wineglass, and answered questions put to the medium by tapping against the side of the glass, once or oftener as the case demanded. Chevreul satisfied himself that the person holding the pendulum was unaware of imparting any movement to it, and he asked himself whether the idea or simple image of a movement would not suffice to bring about this movement. A theory was current that the oscillations of the pendulum were ampler when the ring was suspended over mercury. Chevreul had little difficulty in proving that the mercury had no influence whatever. He demonstrated that the subject's thought (not his will) was the sole cause of the oscillations. This thought acted through the intermediation of imperceptible movements, which were involuntary and unconscious (subconscious).

Starting from Chevreul's classical experiments, I have devised the following exercises, and every one of my new pupils has to perform them.

Materials. In the middle of a sheet of white paper draw a circle, O. Draw a line AB passing through the centre of O. Draw another line CD, perpendicular to AB, likewise passing through the centre of O. These must stand out very distinctly on the white surface. Place the sheet on the ground or on the table in front of the subject, so that the line AB runs from left to right across his field of vision, while the line CD runs from near to far. Give the subject the pendulum, which resembles a miniature fishing rod and line, the pendant be-

ing a *small, heavy,* and preferably *shining* body. The rod and the line should each be about eight inches in length. An ordinary pencil will serve for the rod. The bob of the pendulum should weigh about as much as a new shilling piece. The pupil takes the rod in his hand, and is asked to hold himself upright, but not to press the elbow nervously against the side. It would be a mistake for him to assume a position which would hinder his freedom of movement. The bob of the pendulum will be set in motion, not by any mysterious currents, but by the pupil's own movements, real though imperceptible. These movements must take place *quite independently* of his will. He must be unaware of them or rather, must become aware of them only after they have taken place, so that he regards them objectively, as spectator and not as actor.

First Exercise. The pupil is requested to hold the pendulum in such a way that the bright bob occludes the centre of the circle. The pendant will not be vertically above the centre, but somewhere on the straight line between the centre and the pupil's eye. To get the correct position, the pupil may close one eye. He is now asked to let his mind dwell on the line AB, following it mentally from one end to the other. He is not to make any attempt to swing the pendulum, but is on the contrary to aim at keeping it motionless. We add that there is no difficulty in "thinking well" about the line. It must be done without effort. Enough, we say, to look at the line without losing sight of the bob. In these conditions, we inform him, the pendulum will begin to swing in the direction AB, so that the bob will pass to and fro along this line. It may be well at the same time to sketch out somewhere in the pupil's visual field, with

the finger, with a ruler, or with another pendulum, on a line parallel with AB, a to-and-fro movement which will help to call up in his mind the idea of the expected movement of the pendulum he holds. (This is an accessory, often useful in the early stages, but needless when the experiment has become familiar.) In these circumstances, after a few seconds, or after a few minutes at the outside, the pendulum begins to swing. The amplitude of the oscillations rapidly increases, so much so that some persons feel that the devil must be at work, and drop the bewitched pendulum as if it burned their fingers. But of course this alarm is rare. The very reason why I select the experiment for the initiation into autosuggestion is that it does not seem overwhelmingly marvellous, and is none the less surprising enough to arouse in the pupil an emotional state extremely favourable to suggestion. Children, in especial, do not take fright. They are astonished at first, then amused, and they seldom fail to make a pendulum of their own, so that they can renew the exercise for themselves. This, indeed, is an additional advantage of the experiment. Everyone can easily reproduce it at his own time and pleasure, thus convincing himself that the master's will has nothing to do with the causation of the phenomena, and that they are really the outcome of autosuggestion.

There is yet another good point about this exercise. The shining bob and its regular oscillations tend imperceptibly to induce a slight degree of hypnosis, and this favours suggestion. Spontaneously, therefore, the pupil has learned what is the condition into which he must pass if he is to make effective suggestions to himself.

Finally, when the experiment above described has been perfectly successful, we can easily convince the

pupil, by drawing his attention to the matter, that the more he tries to keep the bob at rest the more ample are its oscillations. This will reveal to him the law of reversed effort.

Second Exercise. The foregoing exercise may now be varied so as to show the pupil how accurately thought transforms itself into visible reality.

While the pendulum is swinging vigorously to and fro along the line AB, we ask the pupil to transfer his thought to the line CD, telling him that the pendulum will spontaneously vary the direction of its swing. If this result be slow in coming, it will be because the subject is hampered by the visual obsession of the movement AB. In that case it will be necessary to put the pendulum at rest. But in most instances this will be superfluous, and the change in the direction of movement will take place without any difficulty.

How does the change occur? Sometimes, the oscillations AB grow less and less extensive, the pendulum becomes motionless, and a moment later the swing in the new direction begins. In other instances, the oscillation AB becomes rounded into an ellipse, with its foci lying over the line CD; gradually this ellipse grows longer and narrower, and is ere long reduced to a line coincident with CD. In yet other cases, the bob continues to swing in a single plane, but the line representing that plane rotates gradually on the centre of the circle O until the line of swing has moved from AB to CD.

If, however, we ask the pupil how it is that a change has ensued in the direction of the oscillation, he is usually unable to answer. His awareness of what has been going on in his mind has been minimal. This fact enables us to reveal to an intelligent pupil the law of subcon-

scious teleology. He has thought the end, and nothing but the end, and his subconscious has devoted its ingenuity to the finding of means (any means will serve) for the attainment of that end. We add: "All healing, all improvement, depends upon the production of movements in one part of the body or another, but it is needless for you to know what these movements are in order that you may bring them about. You need merely think of the end, the cure. You have just learned that your subconscious is a clever physicist. He is just as good a physiologist, and he will find the mean for the fulfilment of the end of which you think he will find them without your knowing anything about the matter."

Third Exercise. Ask the subject to think of the circle, and the movement will become circular. The change may take place by way of motionlessness or by way of an elliptical swing. In a sense this exercise is intermediate between the two foregoing, and we may therefore transpose No. 2 and No. 3. But in passing directly from AB to CD we get a more obvious demonstration of the law of subconscious teleology, for here there is more variety in the choice of means.

Whereas in the linear oscillations there are two points of rest alternating with the motion of the swing, the circular movement is continuous. It may therefore acquire such speed and amplitude that the thread rises nearly to a horizontal plane. When the experiment has reached this stage, the pupil is quite able to isolate himself in a thought. In that case, instead of drawing his attention post factum to the law of reversed effort, we may demonstrate this law by a special exercise, as follows:

Fourth Exercise. Without stopping the movement of the pendulum, we ask the subject to think: "I cannot

stop it." At the same time he is to make efforts to stop it. It will then become apparent that such efforts serve only to increase the activity of the movement, which may become so rapid that the bob ceases to be visible. But directly the pupil discontinues these efforts and lets his thoughts dwell on immobility, the movement grows slower and its amplitude diminishes.

Fifth Exercise. The pupil still holds the pendulum by the handle. In front of him we place an upright placard on which are drawn several letters of the alphabet, ranged along a single horizontal line. The shining bob must be at the level of the letters, and at such a distance that it can strike them in its swing. We begin by asking the subject to think of the fore-and-aft direction. As soon as movement in this direction has been established, we tell him to think of a letter. Without the handle having been displaced in any way, the pendulum changes its plane of oscillation in order to touch the letter thought of. When facility in this exercise has been gained, the placard may have the entire alphabet written on it, still in a single line, and therefore rather small. The pupil must now mentally spell a word, and thereupon each letter as he thinks of it is successively touched by the bob.

One of the most interesting features in this series of experiments is the precision displayed by the subconscious. It often, in this respect, shows greater skill than is seen in the subject's voluntary movements. We take the opportunity of explaining to the pupil that what he has just witnessed and realized is not an exceptional experience, but the manifestation of a general law. We give him typical and concrete instances of spontaneous suggestion, emphasizing at the same time the law of reversed

effort. These explanations must be adapted to his intellectual attainments.

In suitable circumstances, the experiments with Chevreul's pendulum may be supplemented by a demonstration of the well-known phenomena of *cumberlandism.* The pupil is asked to hide some object. He then holds your hand—you, of course, not knowing the hiding-place. He is to concentrate his mind on the thought of this hiding-place. Thereupon, thinking of a direction, he unconsciously impresses on his whole frame, and upon his hand in particular, movements in that direction. You have merely to allow yourself to be guided by these movements in order, in due course, to be able to put your fingers on the hidden object.[1]

Obviously the experiment must be explained to the pupil, if it is to bear fruit in his mind. He must not be allowed to suppose, after the manner of those who witness such feats at fairs or in drawing-rooms, that the discovery of the hidden object is effected by thought-transference. What we have to show him is that as soon as we think sufficiently hard of a movement, our whole body begins to make this movement.

This may serve as an introduction to some account of the way in which our sayings and doings continually reveal what is going on in our subconscious, and to a demonstration that our mental attitude is in the end supreme over events and over what are termed chance happenings.

A good exercise, less new in principle than those with

[1] This experiment is certain to be successful with persons who have had good results with Chevreul's pendulum, and have thus shown themselves extremely sensitive to the ideoreflex force.

Chevreul's pendulum, but well fitted to succeed them, is that of *falling backwards and forwards.*

You ask the pupil to stand upright, the body as stiff as a poker, the feet in close apposition (toes as well as heels), but the ankles being kept flexible, like a well-oiled hinge. Tell him that he is, in fact, to stand like a plank jointed to the floor by hinges, but balanced in an upright position. Point out to him that if such a plank be pulled very gently either forwards or backwards, after it has moved a fraction of an inch it will fall as a rigid mass, unresistingly, forwards if it has been pulled forwards, and backwards if it has been pulled backwards. Tell him you are now going to draw him back by the shoulders, and that he is to allow himself to fall backwards into your arms, unresistingly, turning on his ankles as if they were hinges, while his feet remain motionless as if nailed to the ground.

As soon as he has carried out these orders successfully, you go on to inform him that in the state of unstable equilibrium in which he is now placed, the material impulsion which you communicated to him when you drew his body backwards may perfectly well be replaced by the impulsion of a *thought.* The pupil will merely have to think, "I am falling backwards. I am falling backwards," without meditating in the least as to the consequences of the fall, and he will actually feel himself falling into your arms.[1]

[1] This is advised by Coué as a preliminary experiment. But of late he has dispensed with it, and has contented himself with the experiments to be subsequently described. He finds that the subject is in most cases sufficiently prepared by the emotional atmosphere of the collective sittings—and by the preliminary suggestion exercised by the practitioner's reputation.

To bring this experiment to a successful issue, the experimenter will find it well, as a rule, to sketch out a movement which will help to impress on the pupil's mind the idea, "I am falling backwards," just as in the practice with Chevreul's pendulum it was well for the instructor to move his finger in the direction indicated by his words. The procedure, then, is as follows. Having requested the pupil to hold his head erect and to close his eyes, you will apply your right fist to the back of his neck and your left hand to his forehead. Saying to him several times, "You are falling backwards," or, "Think, 'I am falling backwards,'" you gently draw the left hand backwards over the pupil's temple, without exercising the slightest pressure, and at the same time you slowly but continuously withdraw the right fist.

These manipulations are superfluous in the case of persons who are exceptionally sensitive or who have already had considerable practice in the exercise.

The experiment is likewise practised in the inverse way. The pupil, still in the same attitude of unstable equilibrium, is asked to think, "I am falling forwards," and he actually does begin to fall forwards. This time, since you are facing the pupil, you can tell him to keep his eyes fixed on yours, while you reciprocate. In this manner you will induce a moderate degree of hypnosis, which will be an aid to suggestion.

Another experiment, more striking, which will succeed at the first trial with everyone who has proved very sensitive in the foregoing experiments, is that of the *chair*.

The pupil stands upright behind a chair. He places his hands horizontally on the upper edge of the back, with his thumbs strongly applied to the posterior surface

of the back. He then concentrates his thoughts on the idea: "The chair is rearing up on its hind legs, the chair is pushing me, the chair is rising." At the same time he stares hard at the back, between his thumbs, and presses with the thumbs strongly as if to resist the attempted movement of the chair. But the stronger his resistance, the more rapidly does the chair rear on its hind legs, sometimes with such force that I have seen the subject actually *thrown backwards to the ground.* (It is a wise precaution, therefore, to stand behind him.)

What has happened? Dwelling on the idea that the chair is going to rear, the subject has unconsciously, with the palms of his hands as fulcrums, and in opposition to his conscious efforts with the thumbs, performed all the muscular movements requisite to make the chair rise on its hind legs.

This last exercise will only succeed, as a rule, in persons who have had a certain amount of training. Moreover, there are some subjects who find a difficulty in grasping the state of mind it implies. But the earlier exercises, those with Chevreul's pendulum, and the falling backwards and forwards, are easily performed by everyone.

The pupil should be asked to reproduce them unaided, not merely for practice, but also that he may convince himself that the active force is really that of autosuggestion. The exercise with the pendulum is a good one to repeat before making suggestions to oneself. It may be classed among "exercises in concentration." Moreover, it is excellent for persons who have never witnessed a sitting, and who wish unaided to train themselves in reflective suggestion.

CHAPTER THREE

COUÉ'S PRACTICE

FROM the exercises above described, or from some of them, the pupil may pass to experiments in contracture and inhibition, such as are more familiar to the practitioners of classical hypnotism. At the present time, Coué begins and ends with these. In the conditions under which he operates, they seem to him sufficient. We shall now, therefore, describe the working of Coué's clinic.

It will be well to use his own words in most instances. He describes in the following terms the principle of the experiments in contracture and inhibition:

"Request the subject to clasp his hands and to do so as firmly as possible, until slight tremor ensues. Look fixedly into the subject's eyes, as in the last experiment.[1] Place your hands on his, with a gentle pressure, as if you were going to press more strongly. Tell him to think he is unable to unclasp the fingers, that you are going to count up to three, and that when you say 'three' he must endeavour to separate his hands, thinking all the while, 'I cannot, I cannot, etc.,' and that he will find it impossible to do so. Then count, 'one, two, three,' very slowly, and immediately add, spacing out the syllables, 'You can not, you can not, etc.' If the subject lets his mind

[1] Falling forwards.

dwell adequately on the thought, 'I cannot,' not merely will he be unable to unclasp the hands, but they will grasp one another the more firmly the greater the efforts he makes to separate them. In fact, he will arrive at a result the exact opposite of that which he wishes to attain. After a few seconds say to him, 'Now think, "I can," ' and his fingers will become unclasped.

"Keep your gaze continually fixed on the root of the subject's nose, and do not permit him to turn his eyes away from yours for a moment.

"If the experimenter finds that the subject can unclasp the hands, the experimenter must not think that this is his own fault; it is the subject's fault. The subject has not thought well 'I can not.' Tell him so in confident tones, and repeat the experiment.

"Always use a tone of command, the accents of one who will not tolerate disobedience. I do not mean that the voice should be raised. On the contrary, it is better to speak in your ordinary diapason; but you should space out the syllables in a dry and imperative manner.

"When this experiment has been successful, success will readily be obtained in all the others, provided the experimenter conforms strictly to the instructions given above.

"Some subjects are extremely sensitive, and those of this type can be readily recognized from the ease with which contracture of their fingers and of their limbs can be induced. After two or three thoroughly successful experiments, it is no longer necessary to say to them, 'Think this, think that.' It suffices to say in the commanding tone employed by every good suggester: 'Clench your fist; now you can't unclench it'; or, 'Close your eyes; now you can't open them.' Thereupon, try

as he may, the subject will be unable to unclench his fist, will be unable to open his eyes. A few seconds later say, 'You can,' and the contracture instantly passes off.

"These experiments can be varied as much as you please. Here are some of the variations: the subject places his hands in apposition, and you suggest to him that they have stuck together; he lays his hand on the table and is told that it has adhered to the surface; you tell him that he is glued to his chair and cannot rise; you make him stand up and then tell him he is unable to walk; you show him a penholder lying on the table, tell him it weighs two hundredweight, and that it is therefore too heavy for him to lift; and so on.

"I cannot insist too often upon the fact that in all these experiments the phenomena are not due to *suggestion* properly so called. They are the outcome of the *autosuggestion* which, in the subject's mind, ensues upon the practitioner's suggestion."[1]

Such experiments, as we have said, are familiar to everyone who practises hypnotism. But it is necessary to insist upon the original features they exhibit as performed in Coué's practice.

1. In the first place they are put before the pupil as exercises in autosuggestion, and not as experiments in suggestion. The practitioner begins more or less as follows: "You have come here in search of someone who can cure you. You are on the wrong track. I have never cured anyone. I merely teach people to cure themselves. I have taught many persons to cure themselves, and that is what I am going to teach you. The experiments in which you are about to participate will

[1] Emile Coué, De la suggestion et de ses applications, Barbier, Nancy, 1915, pp. 13 and 14.

always succeed, even if they should seem to fail. For I have never claimed that my thought can realize itself in you. My claim has always been that each person's own thought realizes itself in himself. If, therefore, at the moment when I ask you to think, 'I cannot unclasp my hands,' you think, on the contrary, 'I can,' you will inevitably be able to unclasp them. You may imagine that you have convicted me of error, but in reality you will have proved the soundness of the principle of autosuggestion."

Apart from the educative value of this method of procedure, it has an immediate practical advantage. If an experiment fails, the pupil attributes the failure to his own unskilfulness, and not to the practitioner's impotence. Consequently, he does not lose confidence in the latter.

2. These considerations serve partly to explain the second characteristic whereby Coué's practice is differentiated. I refer to the fact that in his clinic the experiments in contracture are carried out when the subject is in the waking state (or, if you will, in a condition of very slight hypnosis), and that they nevertheless are almost invariably successful, if not at the first attempt, at least after a few trials. Moreover, as has already been hinted, for an explanation of this astounding facility, we must take into account certain causes foreign to the actual procedure. These causes will now be enumerated.

The Nancy sittings are collective. On the average about thirty persons are present at each. While a sitting is in progress, a great many patients are waiting their turn in the garden or in an adjoining room, each with a numbered ticket allotted to him on arrival.

Everyone knows the reputation of the clinic. To the simple-minded it is a place where Coué works miracles. For the first time in the history of mankind, a genuinely scientific practitioner is the object of a collective faith analogous to that inspired in earlier days by certain mystics and charlatans. *The public on which Coué acts by suggestion is a public on which suggestion has already been at work.* It is not surprising that, with such a public, he has no need to employ preliminary exercises.

Furthermore, the sitting itself is methodically utilized to superadd the force of example to the force of this preliminary suggestion based on reputation. The newcomers sit among persons who have already attended numerous sittings, and who make no secret of their progress towards health. From sitting to sitting, each patient can see how the others improve, can see how paralytics walk, how the deaf hear. Besides, the exercises are repeated by the old patients under the eyes of the new; and not until then do the new patients make trial for themselves. In these conditions, in such an atmosphere, it is natural that experiments in the production of contracture should almost invariably succeed after Coué has looked the patient in the eyes for a few seconds. We can understand why he has found it possible to discontinue the preliminary exercise of falling backwards or forwards.

In my own view, exercises in contracture should not be invariably prescribed as preliminary exercises. It is from necessity rather than on account of their intrinsic value that Coué has chosen them for this purpose. They can be realized more speedily than others, and speed is of the first importance to one who has to convey suggestions to a hundred persons or more daily.

Nevertheless, as preliminary exercises, these exercises in contracture are not free from drawbacks. Although they are rendered more acceptable to the pupil by the idea that their essential cause is autosuggestion, none the less there remains in his mind the feeling that a suggestion of impotence has been conveyed, that in greater or less degree there has been an attempt to limit his free-will. To many persons this is distasteful. Even when the experiment succeeds, their vanity sets repression to work, and they persuade themselves that there was little success or none. To a large extent this conviction is illusory, like the familiar belief, on the part of the subject who has been completely hypnotized, that he did not really go to sleep. But the illusion suffices to neutralize the good effects of the experiment. Were it not that the pupil's confidence is reanimated by the contagion of example, by the sight of the cures worked upon others, it is probable that the results would be unsatisfactory.

That is why I consider it preferable, as a matter of principle, to begin with *exercises which give the subject the feeling that he is increasing his own powers,* rather than with those which suggest impotence. Then there will be no unavowed thoughts. Particularly valuable in this respect are the exercises with Chevreul's pendulum, where the subject is amazed and delighted to find that, by his thought, he gives movement, and, so to say, life, to an inert object.[1]

[1] Children who perform this experiment have the feeling that the bob of the pendulum is alive. That is why they find the experiment so fascinating. A little Russian boy said to me: "I speak to my bob; I say to it, 'Go to the right, turn in a circle, stop.' And I speak to it in Russian, for it understands Russian better than French."

On the other hand, we are so much accustomed to do whatever we like with our hands, that experiments tending to produce contracture of the hands are apt at first to seem incredible. For this reason, they may fail. Even if they succeed, we are very ready to think we have deceived ourselves. But when some apparatus with which we are entirely unfamiliar, such as Chevreul's pendulum, is put into our hands, we are unprejudiced, and are quite willing to expect novelties from its use.

I must not be understood to imply that Coué's methods, as above described, ought to be abandoned. Their very inconveniences have, as obverse, advantages which are no less real. Their incredibility, once the pupil has recognized that these marvels actually happen, serves but to heighten conviction and to impress the imagination. As for the suggestion of powerlessness, it is an excellent means for throwing into relief the law of reversed effort. This is why Coué, for whom this law is the chief guiding principle, prefers the methods he has chosen.

Whatever may be the rights of the matter, I opine that in ordinary practice it will be better to begin with other exercises. These will very likely suffice. Experiments in contracture may be reserved for especially sensitive subjects, in whom they are certain to succeed. For the rest, we should assure our pupils that *all the exercises have the same educative value,* and that it matters little which particular group is chosen for practice.

Having made these reservations, I will return to the exposition of Coué's methods, and will once more allow him to speak for himself.

"When the subject has passed through the foregoing experiments, he is ripe for curative suggestions. His

mind is tilled soil, in which the seed can germinate and grow to maturity. Before, it was uncultivated ground, where the seed would have perished from drought.

"Whatever the patient's trouble may be, whether bodily or mental, the same procedure is applicable, and the same formulas are employed, with trifling individual variations.

"You say to the subject: 'Sit down and close your eyes. I shall not attempt to put you to sleep, for it is needless. I ask you to close your eyes for the simple reason that I do not wish your attention to be distracted by the objects within your field of vision. Now say to yourself earnestly that all the words I am going to utter will fix themselves in your mind, will be graven there, that they must always remain fixed and graven there, permanently impressed, so that, without any exercise of will, without your knowing anything about the matter, quite unconsciously on your part, your organism and yourself will have to obey them. I tell you first of all that every day, three times a day, morning, noon, and evening, at mealtimes, you will be hungry, that is to say, you will experience that pleasant sensation which makes us think and say, "Oh how I should like something to eat!" You will, in fact, eat with great satisfaction, but you will never overeat yourself. You will eat enough, neither too much nor too little, and you will know that you have eaten enough when something says within you, "You have eaten enough." Then you will stop, for you must eat no more. In these conditions, having eaten with appetite, and having eaten no more than you should, you will digest well, that is to say, you will have no discomfort whatever, either in the stomach or in the bowel, no uneasiness or pain of any kind. Assimilation will be

perfectly performed, and your organism will make the best possible use of the food to form blood, muscle, strength, energy—in a word, to create life.

" 'Since you have digested well, the excretory functions will be well performed. Every morning, on rising, you will feel a desire to go to stool. Without the use of laxative medicines, and without recourse to any other artificial means, you will have normal and satisfactory evacuations.

" 'Every night, as soon as you wish, you will go to sleep, and you will go on sleeping until the time at which you wish to wake next morning. You will sleep calmly, soundly, quietly. You will have no nightmare. When you wake up you will always feel well, cheerful, thoroughly fit.

" 'If you have sometimes been melancholy, gloomy, out of sorts, filled with forebodings, henceforward you will be free from such troubles. Instead of being moody, bored, unhappy, anxious, you will be cheerful, thoroughly cheerful, happy with no good reason for it perhaps, but then in the past you may often have been unhappy with no good reason for it. Nay more, even if you have serious cause for unhappiness, for melancholy, you will have no such feelings.

" 'If, at times, you have been impatient or angry, you will no longer be anything of the kind. On the contrary, you will always be patient, and henceforward the happenings which used to irritate you will leave you perfectly unmoved.

" 'If you have occasionally been haunted by evil and unwholesome ideas, by fears or by phobias, I assure you that these ideas, these fears, these phobias, will gradually cease to trouble your imagination; they will seem to

melt away, to pass into a distant cloud where everything vanishes.

"'I add that all your organs work perfectly. Your heart beats normally and the circulation goes on as it should. The lungs act well. The stomach, the intestine, the liver, the gall-bladder, the kidneys, the urinary bladder—all do their duty. If any one of the organs named is actually out of order, the disturbance will lessen day by day, so that within a brief period it will have entirely disappeared, and the normal function will have been restored.

"'If, in any organ, some structural lesion should exist, this physical disorder will rapidly be relieved, and a complete cure will speedily ensue.' (I should mention that we can cure an affected organ without knowing that it is actually out of order. Under the influence of the autosuggestion, 'the affected organ will be restored to health,' the unconscious, which knows what organ is involved, will do all that is required.)

"To these general suggestions, which may seem perhaps a trifle tedious, and which to some may even appear childish, but which are *indispensable,* must be added those which apply to the special case of the individual subject you are treating.

"All these suggestions must be made in monotonous and soothing accents, with due stress on the more essential words. Your tone should invite the subject, if not actually to fall asleep, at least to grow somewhat torpid, so that his mind becomes a blank.

"When the list of suggestions is finished, you address the subject as follows: 'To sum up, I mean that in all respects, alike physically and mentally, you will henceforward enjoy excellent health, better health than you

have hitherto enjoyed. Now I am going to count up to three. At the word, "three," you will pass out of the condition in which you now are, will pass out of it quite quietly. When you do so, you will wake up thoroughly; you will not feel drowsy or tired; on the contrary, you will feel strong, alert, fit, full of life and vigour; furthermore, you will feel bright and cheerful, will feel well in every respect. "One, two, three." '

"At the word 'three,' the subject opens his eyes, smiles, and has an expression of contentment and well-being.

"Sometimes, though this rarely happens, he is cured on the spot. More often, he is better, his pain or his distress of mind has wholly or partly disappeared, but only for a season.

"In any case, the suggestions must be renewed from time to time. The requisite frequency varies in different subjects. Always, as improvement is more marked, the intervals between the sittings can be extended, until the time arrives when the treatment can be completely discontinued—this of course being when cure has taken place.

"Before dismissing the patient, tell him that he carries within him the means of cure; that you yourself are merely an instructor, who can teach him how to use this means; and that he must aid you in your task.

"Every morning, therefore, before rising, and every evening as soon as he has gone to bed, he is to close his eyes and to imagine himself in your presence. Then he must repeat fifteen or twenty times the phrase: *'Day by day, in all respects, I get better and better.'* As he does this he must mentally underline *'in all respects,'* since this includes every kind of trouble, mental as well as

LEGISLATIVE LIBRARY ONTARIO

bodily. Such general suggestion is more potent than particular suggestions.

"From what has been said it is easy to grasp the rôle of the suggester. He is not a master who issues orders; he is a friend; he is a guide who conducts the patient, step by step, along the road to health.

"Since all the suggestions are made in the patient's interest, his unconscious asks no better than permission to assimilate them and to transform them into autosuggestions. When this has been done, cure follows more or less rapidly."[1]

At collective sittings, the general suggestions, which are the same for all the patients, are formulated once only. When the time has come for individual suggestions, the practitioner goes up to each patient in turn, touches him, and speaks to him of the topics with which he is specially concerned. Veiled terminology can be employed in relation to any matter to which open allusion might be indiscreet. While these individual suggestions are in progress, the patients who are not at the moment engaging the practitioner's attention remain motionless, with eyes closed and muscles relaxed. The monotonous tone of the operator is intended to exercise a soothing influence, and does in fact lull the patients. This is the only hypnotizing factor, and it proves sufficient, without arousing alarm in anyone. The hypnosis thereby induced, commonly the slightest degree of hypnosis, is just as natural as that brought about by a cradle-song, or that due to the rustling of branches in the breeze which lulls you to sleep as you lie beneath a tree. We are at the very antipodes of the barbarous methods of the Salpêtrière school.

[1] Coué, op. cit., pp. 14-17.

CHAPTER FOUR

CONCRETE RESULTS

(*Suggestion and Psychoanalysis*)

Liébault and Bernheim declared that they succeeded in conveying effective suggestions to at least 90% of their subjects. Vogt and Forel speak of successes with 97%. Coué claims to have exceeded the latter percentage by a few tenths. He considers, in fact, that only two classes of persons are permanently rebellious to the exercises, and consequently refractory to the method. In his own words, these classes are composed of:

"1. Persons whose mental development is so backward that they cannot understand what you say to them.

"2. Persons whose level of intellectual culture is high, but who are so fickle-minded that they are incapable of *consciously* devoting their attention to a single idea for the space of a few seconds."[1]

He adds that these two classes, taken together, "represent barely 3% of the population."[2]

Let me add that, in my own view, persons in the second class ought not to be abandoned without a trial. Moreover, as I have shown, certain persons are rebellious to contracture experiments for reasons very different from inconstancy of mind. In any case, by the use of the pendulum experiments we can unquestionably increase the proportion of persons found amenable. Provisionally I feel entitled to speak of about 98% of the population as susceptible. Future experience will enable us to obtain more precise statistics.

[1] Op. cit., p. 11. [2] Op. cit., p. 17.

If by the new methods we can secure but little increase in the proportion of *persons* amenable to suggestion (and, indeed, above 97% there is not much scope for increase), it might none the less seem that we could hope to secure a considerable increase in the proportion of *cases* amenable to suggestive treatment. Unfortunately a "case" is a less definite entity than a person, and percentages here would be artificial. But this much can be asserted. The method expounded in the present work has secured incontestable results *in cases alleged to be incurable, in patients given up by practitioners employing only the conventional methods of treatment.* The statement conflicts with received ideas, but we must bow before the facts. There are, of course, systematists who persist in denying facts in the name of principle—as if a principle were anything more than a formula synthetizing a certain number of known facts; as if a principle could refuse to grant new facts the right to contradict it. Those who will deny a fact in the name of a principle are like a child which, having seen lions only in cages, denies a priori that lions can exist free. As Arago said, he is a rash man who pronounces the word "impossible" anywhere outside the sphere of pure mathematics.

Let us dismiss theory for the nonce, and let us examine the facts. These facts have been observed under conditions which give guarantees for all desirable accuracy of observation.

In the psychonervous domain, the methods of the New Nancy School have given remarkable results in cases where ordinary psychotherapy had failed. Here are two striking instances:

1. Y., of Nancy, neurasthenic for some years past, suffers from phobias, from terrors. The gastric and intestinal functions are badly performed. He does not sleep well. He is gloomy, and is troubled with thoughts of suicide. He sways like a drunken man when he walks. His mind dwells unceasingly on his symptoms. *Treatment has hitherto proved unavailing, and he continually grows worse. A month at a special institution did him no good whatever.* The patient consulted Coué in the beginning of October, 1910. The preliminary experiments were fairly easy. The practitioner explained the autosuggestive method, the existence of the unconscious, etc. Suggestion. For two or three days Y. found these explanations rather difficult to follow. Then the light broke in upon him. "I understand," he said.—Suggestion, followed by daily autosuggestion. Improvement was slow at first, but soon became more speedy. *A complete cure was effected in six weeks.*[1]

2. R. de B. has suffered from neurasthenia for *more than twenty years.* Has consulted celebrated specialists in Nancy (Bernheim), Paris, Strasburg, Berne (Dubois), etc. Has paid long visits to some of these specialists, but the results have always been negative. Came to consult Coué in July, 1915. Improvement followed the very first visit. After each consultation a further advance could be noted, and at the end of three months the patient declared himself "well, and indeed very well"—the bombardment of the city notwithstanding.[2]

The cure of neurasthenia is often unexpectedly rapid. Let me give another of Coué's cases, which is typical:

A lady came to consult him. Her sister had suffered

[1] Op. cit., p. 24.

[2] Unpublished.—Privately reported to Baudouin by Coué.

from neurasthenia complicated with various functional troubles, and had been cured by the Nancy method. The new patient likewise suffered from neurasthenia, in an extremely aggravated form. She spent quite half her time in bed, utterly unable to get about or to do any work. She had a bad appetite, poor digestion, low spirits.—Cure followed a single sitting.—The case was followed up for two years, during which time there was no relapse.

It is impossible to find room for cases of all functional and organic diseases. The reader must be content with a record of instances where the results have been exceptionally striking or peculiarly novel.

I

In the study of spontaneous suggestion, special mention was made of the action of the mother's brain upon the fœtus, of the action of the mind on the mechanisms of pregnancy, childbirth, etc.—Induced suggestion has been proved to exercise a notable influence upon the female pelvic organs.

Coué has repeatedly found that, on the average, his method will cure severe metritis in six weeks. Here are some examples:

1. Woman suffering from metritis and salpingitis. Considerable relief was noted after the first sitting. Complete cure in five weeks, confirmed by the patient's regular medical attendant. (1915.)

2. Woman aged 30, metritis of six years' duration. Her doctor considered operation indispensable. Dreading this, the patient wished to try suggestion as a last resort. Cure was instantaneous, the success being doubt-

less due in large measure to the emotional state arising from the fear of operation. Kept under observation for six months, during which there was no relapse. (1915.)

3. Woman aged 28, metritis and salpingitis of long standing (several years). Same result. (1915.)

4. Woman aged 60; metritis for the last twenty-four years; grows steadily worse. Operation thought indispensable. Complete cure in six weeks from suggestive treatment. Confirmed by the surgeon who had been going to operate. (1915.)[1]

These examples of recent date have been chosen because of their striking characteristics. Earlier instances, which it is needless to record, show that the cures are lasting.

The New Nancy School has to its credit several cases in which typical fibromata have completely disappeared under treatment. This phenomenon does not differ in essence from the disappearance of a wart. As Coué has well said, the process is explicable in the same way as is the arrest of hæmorrhage by suggestion. We must assume in both cases that the vasoconstrictor system is at work. The difference lies in the duration of the suggestive action, and in the magnitude of the result.

II

We have likewise seen spontaneous suggestion at work in the cure of tuberculosis, and we have examined some of the statistics Louis Rénon has published, statistics which clearly prove the reality of this action. Since,

[1] Cases 1 and 4 were published in the Bulletin Ecole de Nancy for the year 1915. Cases 2 and 3 were privately communicated.

however, in the Nancy cases, autosuggestion is systematically employed, we need not be surprised to find that Coué's results are yet more remarkable than those recorded by Rénon. (Supra, pp. 114 et seq.)

Some of his cases tend to revolutionize our views.

1. Woman of thirty, in the third stage of pulmonary consumption. Increasing emaciation, notwithstanding hyperalimentation. Cough, shortness of breath, expectoration; seems to have only a few months to live. Preliminary experiments indicate great sensitiveness. Suggestion, immediate improvement. From the next day, a decline in the morbid symptoms begins. Improvement continues from day to day; the weight increases rapidly, though hyperalimentation has been discontinued. After a few months the cure seems complete.—This patient lived at Troyes. In May, 1910, Coué finally left Troyes for Nancy. On January 1, 1911, Madame D. wrote him a letter of thanks, informing him that she was pregnant, and was in splendid health.—A later report showed that there had been no relapse.[1]

2. A lad of fifteen has a swelling of tubercular origin on the right arm. It is four inches long, two inches wide, and one inch in thickness. Completely cured at Nancy in four months.[2]

3. I was able to observe a similar case in Geneva. A little girl aged 11, suffering from tuberculosis, was brought to me at the Jean Jacques Rousseau Institute in November, 1915. On the temple was a tubercular ulcer, the size of a florin. It dated from four months back, and had obstinately refused to heal under treatment. The child proved sensitive and confiding. Suggestion. Autosuggestion carried out by the patient conscien-

[1] Coué, op. cit., p. 23. [2] Privately communicated.

tiously every morning and every evening. Great was my astonishment, and equally great was the astonishment of my pupils, when the girl returned a week later with the ulcer already cicatrized. The epithelium covering the surface was still diaphanous, and pink in colour. A few weeks later the appearance was almost normal. Within a month from the date of the first suggestion the cough had completely disappeared, although the time was the middle of winter. Next month a slight bronchitis supervened, and was cured without difficulty. Appetite had become normal; sleep was uninterrupted, lasting from eleven to twelve hours. Rabinovitch, who has kept this case under observation, tells me that the improvement has continued, although the patient (whose family is in humble circumstances) lives in a damp ground-floor tenement and in hygienic conditions otherwise unfavourable.

4. In view of the results above recorded, it will not surprise the reader to learn that two cases of Pott's disease (tubercular curvature of the spine) have been benefited by treatment at Nancy.

III

Having dwelt on two classes of cases, uterine inflammation and tubercular disease respectively, let us now consider certain isolated examples which show how various are the disorders to which the method is applicable. The first case is quoted from Coué (op. cit., p. 23).

1. A. G., of Troyes, has for a long time suffered from an intractable enteritis. Mental condition bad. The patient is low-spirited, gloomy, and unsociable. He is much troubled with ideas of suicide.

Preliminary experiments easy; followed by sugges-

tion, the results of which were appreciable from the very first day. Suggestion practised for three months, daily at first, and subsequently at increasing intervals. At the end of this time the cure was complete, the enteritis having entirely disappeared, and the mental condition being all that could be desired. The cure dates from five years ago, and there has never been the slightest tendency to relapse. The patient is a conspicuous example of what can be done by suggestion, or rather by autosuggestion. The suggestions bore upon the mental condition as well as upon the physical, and both kinds were accepted with equal facility. Thus he acquired increasing self-confidence. Being an excellent workman, and wishing to earn more money, he wanted to have a hosiery frame in his own house, so that he might work at home for an employer. After a while, a manufacturer who had seen him at work, entrusted him with the frame he coveted. G. was so skilful that he was able to turn out far more from his frame than other workmen were able to produce. Delighted with this result, the manufacturer entrusted him with another frame, and then with a third. Now G., who would have remained an ordinary workman but for suggestion, is the master of six frames, which bring him in quite a considerable income.

Within a few years (as I prophesied to him three years ago) G. will have become one of the leading manufacturers of Troyes.

2. A woman of Nancy had suffered for three years from an intractable eczema of the hands. Cure was effected by suggestion in a few sittings. (1914.)[1]

3. Jacqueline G., aged 7; of Neufchâteau (Vosges), where I was living in 1915, was brought to me by her

[1] Bulletin Ecole de Nancy, 1914.

mother on the advice of an elder brother who had been cured of stammering by autosuggestion.

The child had suffered from typhoid when 14 months old. Since then she had been totally deaf, and she was able to produce nothing but inarticulate sounds, comprehensible only to her habitual associates. The medical opinion was that there was no hope of cure, and it was proposed to send her to a special institution for the training of deaf-mutes. An idea of the intensity of the deafness may be derived from a picturesque phrase of her own, "I hear the piano with my feet," meaning that she could feel the tactile vibrations transmitted through the floor from the instrument, but could not hear any sound. Intelligent, full of vitality, and very sensitive to suggestion.

After six weeks' treatment, during which she had sittings twice a week, she was able to utter all the sounds of the alphabet. The only consonants she had any serious difficulty with were ch, j, s, and z. She learned several new words every day, fixing them in her memory by writing them down. She could sing, with the words, an air which had been sung before her with a pianoforte accompaniment.

It is well to point out that the child religiously formulated her daily autosuggestion. For this purpose she buried her head beneath the bedclothes, and would allow nothing and nobody to distract her attention.

4. B., sometime clerk of the civil court in Nancy. Has suffered for twenty-five years from an affection of the frontal sinuses; has had *eleven* operations, which have failed to cure. Physical condition deplorable; mental state even worse. Cannot read for ten minutes a day, is fatigued by the slightest movement, suffers

LEGISLATIVE LIBRARY ONTARIO

from insomnia, has severe and almost constant pain in the head, is incurably low-spirited. This patient came to consult Coué on the recommendation of R. de B. (see above, p. 273). The first four sittings seemed to have no effect. During the fifth sitting improvement was obvious, and became more conspicuous sitting after sitting. After three months the patient said to Coué: "I passed such a day yesterday as I have not known for years. I was entirely free from headache; I took a long walk without feeling the least bit tired; I was able to read without difficulty for four hours." He was cured. There was no relapse. (1915.)[1]

Enough cases have been enumerated to prove our point.[2]

As a rule, even when at the first sitting the subject has shown a satisfactory grasp of the mechanism of autosuggestion, we shall facilitate his progress by asking him to attend further sittings, twice a week at first, then once a week, and thenceforward once a fortnight or once a month for a time. As when swimming is being taught, the pupil must not be left to himself too soon.

Most people, in fact, are greatly influenced by what is said and thought by those with whom they associate. The arguments of routinists and professional sceptics end by shaking their nascent confidence, above all when these arguments are dinned into their ears day after day, or are presented in an elegant and logical form by a man who is cultivated though superficial. Those only who can think for themselves, those who do not estimate the truth of an idea by the number or the vivacity of the

[1] Privately communicated.

[2] A detailed register of cases is kept in the archives of the Jean Jacques Rousseau Institute at Geneva.

tongues that defend it—and such persons are rare—can readily dispense with lessons in suggestion. The others, the majority, will do well to steep themselves from time to time in the atmosphere of the sittings.[1]

Moreover, in the sitting, the ideas which form the object of suggestion are proposed to the subject without any effort on his part, for they are formulated by another. (Theoretically, a phonograph might do this as well as a living person.) All that the subject has to do is to watch the flow of ideas as he watches the succession of pictures on a screen; whereas in autosuggestion in the strict sense of the term the ideas must be initiated by the subject himself, and this requires at least a minimum of effort. At the outset, there is a risk that the subject will exaggerate the effort. When suggestion is induced by another, effort can be entirely relinquished, and it is therefore easier for the subject to realize the state of relaxation requisite for the working of autosuggestion. We know, indeed, that autosuggestion is fruitful precisely in proportion as it is distinguished from voluntary effort.

The number of sittings requisite for cure will obviously vary, in different subjects, and still more in different cases.

From this point of view, cases of peculiar interest are those in which *the morbid state is autosuggestive in origin and simulates a bodily disorder.* Here a counter-suggestion sometimes brings about immediate cure. Such a cure may even be regarded as a criterion on

[1] From this outlook, the reading of a manual may take the place of sittings. The author hopes that his book may serve such a purpose.

which we can base the assertion that the trouble was solely due to spontaneous autosuggestion, that there was no organic lesion whatever, that the whole thing was due to unconscious simulation. (See Part I, Chapter VIII, Conditional Suggestions; refer also to the example of subconscious teleology given in Part I, Chapter X.)

Here are examples of such immediate cures, where the countersuggestion has instantaneously neutralized the earlier autosuggestion.

1. A woman of Nancy, 80 years of age. For three years she had suffered from generalized pains which made it impossible for her to get about without the aid of two walking-sticks. She was able to leave the first sitting unassisted by these sticks, and she no longer uses them.[1]

2. Professor Gillet of Belfort suffered from aphonia. He could begin speaking in normal tones, but the aphonia invariably came on after he had spoken for ten or fifteen minutes. *Various doctors were consulted, and not one of them could discover any lesion in the vocal organs.* One of these advisers, however, said the patient was affected with "senility of the larynx," and this confirmed him in the notion that he would never recover. He came to Nancy during the vacation. A lady advised him to consult Coué. He refused for a time, but finally agreed to do so, notwithstanding his absolute unbelief in the effects of suggestion.

Coué made some suggestions to him none the less, and asked him to return two days later. When he kept the appointment, he said that on the previous day he had been able to converse for two hours without becoming

[1] Privately communicated.

affected with aphonia. On his next visit, four days from the first, there had been no return of the aphonia, although he had not only spoken freely in the interval, but had even sung. He was cured.

Since then Professor Gillet, freed from his simulated infirmity, has been able to continue his university career. He has become one of Coué's disciples. In the Bulletin Ecole de Nancy for the year 1913 he published a study of autosuggestion from which we had occasion to quote on p. 107.[1]

3. Louis Schmidt, aged 44, of Jézainville (Meurthe et Moselle), had an attack of indigestion, as a sequel of which he became affected with almost complete paralysis of the arms and legs. He was sent to the departmental infirmary, and remained there for a while without improvement. When he came to consult Coué, he could hardly walk; his legs, he said, were "like cotton-wool." After the first sitting, he could walk, and could even run. He had a relapse a few months later, but was restored to health once more by suggestive treatment.[2]

4. A soldier wounded in the war and invalided out of the army was unable, despite mecanotherapeutic treatment, to move his right leg except with the jerky impulsion of an artificial limb. Cure ensued upon the first suggestion.

Strange as are these cases of autosuggestive simulation which yield promptly to a countersuggestion, perhaps yet more remarkable are cases which appear precisely similar, cases in which, as in the former group, there is no trace of organic lesion, but which prove *more rebellious to suggestive treatment than do many cases that are*

[1] Gillet's own case is reported by Coué, op. cit., p. 26.

[2] Reported by Coué in the Bulletin for 1914.

indisputably of organic origin. Consider the following instance:

Miss M., aged 30, of Nancy, had suffered for six years from violent pains in the bladder. She had been treated by various methods, and had been subjected to an operation, with the result that she was informed by the surgeon *there was no organic lesion.* "It's all nerves!" he told her. "I can do nothing for you." Thereby he intensified the pernicious autosuggestion, and the patient grew worse. At length she sought Coué's advice. The suggestion he induced had to struggle with the antecedent suggestion, and it was a long time before the countersuggestion could get the upper hand. Progress followed each sitting, but the advance was almost imperceptible. So deep-rooted was the prior suggestion that *eight months* were requisite for the cure.[1]

This is not an isolated example. It appears, rather, to be typical of an important series. The question therefore arises, why these cases of autosuggestive simulation are sometimes perfectly easy to cure by a countersuggestion, and why the cure is sometimes so difficult. The difference between the two types is remarkable, and cannot fail to rivet the attention. The cause must doubtless be sought in the special characteristics of the antecedent spontaneous suggestion. As far as our knowledge goes (which is not very far), we may formulate the following hypothesis:

1. Sometimes the antecedent spontaneous suggestion is the outcome of a simple idea, one that is not ramified, one that is isolated in the mental mass. In that case the idea is as easy to eradicate as the "I cannot unclasp

[1] Privately communicated.

my fingers'' of the contracture experiments. A single countersuggestion is enough.

2. Sometimes, on the other hand, the spontaneous suggestion has struck roots in all directions; the threads of subconscious association spread throughout the mental mass; we are no longer confronted with a simple idea, but with what the psychoanalysts have termed a *complex,* an integration of images, memories, sentiments, conscious and unconscious reasonings, interlacing one with another, and to all appearance inextricably intertangled.

Upon psychoanalysis devolves the task of reconstituting these complexes, and consequently also the task of verifying the foregoing hypothesis. It may be added that when there has been *spontaneous suggestion by complex,* the indication is rather for psychoanalytic treatment than for simple suggestive treatment.

In exemplification of what has just been said, let me briefly recount the case of Miss B. M., aged 27, a case subjected to psychoanalysis. She suffered from quite a number of morbid symptoms, whose root cause was revealed by the analysis to be a scarcely acknowledged wish for a life spent in more comfortable circumstances, where she would have fuller opportunities for intellectual development. One of the symptoms was a severe neuralgia of the arm. Suggestion from me and autosuggestion on the patient's part led to its improvement, but not to its cure. I learned from the analysis that this symptom was due to subconscious imitation. In earlier days a schoolfellow of the patient, suffering from an accident affecting a paralyzed arm, had, owing to this accident and to the consequently enforced confinement to a couch, secured the leisure which enabled her to achieve

an intellectual development excelling that of her companions. From the day when this cause was explained to my patient, the neuralgia disappeared never to return.[1]

For cases in which the morbid symptoms are due to spontaneous suggestion by a simple idea, psychoanalytic treatment can never compete in rapidity of cure with suggestive treatment, for the latter, as we have seen, may give instant relief. But where the trouble is due to spontaneous suggestion by complex, psychoanalytic treatment, though tedious, may save time in the end, and may give more satisfactory results. If I may use the similitude, psychoanalytic treatment is to suggestive treatment what algebra is to arithmetic. It complicates simple problems, but it simplifies complex problems.

When therefore we have a *malady* probably due to autosuggestion, a malady which proves rebellious to treatment by the Nancy method although the *patient* is not in general refractory to that method, we should have recourse to psychoanalysis.

When, on the other hand, it is the *patient* who is refractory, when he finds it difficult to grasp the mechanism of autosuggestion, when he makes too much effort, when he proves unable to isolate himself and to concentrate satisfactorily, etc.—the indication is, with the subject's consent, to have recourse to *profound hypnosis* or induced sleep, which, according to the commonly received opinion, "increases suggestibility." But now, before dealing with the question of hypnosis, we must clear up the problem of suggestibility.

[1] This case was recorded by the author in the Archives de psychologie, December, 1916, Kündig, Geneva.

CHAPTER FIVE

ACCEPTIVITY AND SUGGESTIBILITY

Let us recall the definition of suggestion given in the Introduction to the present work.

In heterosuggestion, the only kind of suggestion usually considered, we recognized the presence of two phases:

1. An idea, imposed by the operator, is accepted by the subject.

2. This idea undergoes transformation within the subject into the corresponding reality.

According to the prevalent view, the essential phase of suggestion is the first of these two phases. It is upon this that the definition of suggestion must be based. But in our view the second is the essential phase. Suggestion, we contend, is not a phenomenon characterized by the movement of something from the operator to the subject. It is a psychophysiological phenomenon comprised within the mind of the subject. Thereon must be based our theory of autosuggestion.

Let us, therefore, distinguish the two following phases:

1. *Acceptation.*

2. *The ideoreflex process* (which, for us, is suggestion).

This distinction is vital, but writers on this subject

have failed, hitherto, to draw it with sufficient clearness. While they incline to one opinion or the other, to the view that suggestion is comprised in the former phase, or to the view that suggestion is comprised in the latter, they fail, as a rule, to differentiate accurately between the two outlooks. In practice they continue to regard suggestion as an integral and synthetic phenomenon, the product of two factors: an idea proposed by the operator, accepted by the subject, and realized by the latter. Their formula would run:

$$\text{suggestion} = \text{acceptation} + \text{ideoreflex process.}$$

What is *acceptation?*

We have already employed this term when speaking of suggestions proposed in the state of profound hypnosis (see Part III, Chapter I). We then caught a glimpse of the truth that acceptation must not be looked upon as an act of conscious and deliberate will. We can now go further than this. The term "acceptation" connotes the notion that the idea penetrates the mind in virtue of a consent which in other cases might be withheld; that the will and the intelligence are in abeyance; that the idea is not consciously controlled, but is the object of a spontaneous adhesion. In a word, *it is not the conscious but the subconscious which accepts.* The idea, instead of being confronted with others and judged from an intellectual and volitional viewpoint, is granted hospitality like a welcome stranger. It remains isolated, and therefore is not subject to contradiction.

We may speak of acceptation, not only in heterosuggestion, but also in spontaneous autosuggestion. In the latter, as well as in the former, an accepted idea is an

idea implanted in the mind without the exercise of any control.

Credulity, routine, indifference, confidence in the hypnotizer, the latter's "personal influence"—all these are factors of acceptation.

Now acceptation, by isolating the idea, by avoiding the establishment of associative and intellectual regulatory relationships between this idea and others, favours a concentration of the mind upon the accepted idea, and consequently favours suggestion. But acceptation is not itself suggestion, either wholly or in part.

The same confusion is met with when we pass from the question of suggestion to that of suggestibility.

By the suggestibility of any person, we mean the readiness with which, on the average, that person will realize a suggestion.

Thus, as the definition of suggestion varies, the definition of suggestibility will vary concomitantly. For most writers, suggestibility means the ease with which the subject realizes the ideas proposed by the operator. For us, on the other hand, suggestibility denotes the ease with which the second phase of the phenomenon ensues, whereas for the ease of acceptation we propose to use the term *acceptivity*.

The distinction becomes necessary for those who, like ourselves, take their stand upon autosuggestion. Let us consider reflective suggestion, which is our ideal. It presupposes that the ideas, the objects, of our suggestions, have been deliberately, intelligently, chosen; its primary function is to strive against harmful spontaneous suggestions, and to repair the damage these have caused. Far from implying the passive acceptation of

the ideas which pass through our minds, it exacts from us unceasing *self-control.* It insists that there shall be a strict frontier customs service, ever on the watch to prevent the ingress of undesirable ideas. To sum up, whereas acceptation, or the absence of control, is an adjuvant to heterosuggestion and spontaneous suggestion; on the other hand, non-acceptation, or control, is the primary condition for the practice of reflective autosuggestion. It is here that the confusion becomes serious.

Binet, faithful to his definition of suggestion, tends to identify suggestibility with what we have termed acceptivity. The experiments whereby he measures "suggestibility," serve rather to measure acceptivity, to measure mental passivity.[1]

Let us consider some of these experiments.

First Series (suggestion produced by the influence of a guiding idea).

Children are shown a drawing of twenty lines in series. The length of these lines increases up to the fifth, but the others are all of equal length. Having looked once at this drawing, they have to reproduce it from memory. Most of them draw the lines of increasing length beyond the fifth, and often up to the very end of the series.

Second Series (suggestion produced by personal influence).

Wools of various colours are shown to a child. When we are sure that it knows the names of all the colours, it has to write these names down. As it is writing, the name of some other colour is suggested, verbally. Often the child writes down this latter name.

[1] Binet, La suggestibilité, Paris, 1900; Giroud, La suggestibilité dans les enfants de l'école, Année psychologique, 1912.

The experiments of the first series bear upon spontaneous suggestion; those of the second series, upon induced suggestion. They can have no bearing on reflective suggestion, for in this the acceptivity would run counter to the suggestibility, and no confusion could possibly arise. Binet, however, appears to ignore reflective suggestion.

The kind of acceptivity shown in the experiments, which is for Binet suggestibility, obviously puts the subject in a worse position than if he were devoid of it. Binet, therefore, draws the following conclusion:

"If we point out to the children the mistake they have made, if we show them how they came to make it and where their attention lapsed, they simultaneously receive a lesson in things and a lesson in morals. The teaching is often profitable. In many instances, as test succeeds test, the pupils learn to avoid these errors, and become less suggestible."

We see at once how necessary it is that this mental passivity should no longer receive the name of suggestibility, since the latter term is likewise used to denote the faculty an idea has of realizing itself by a subconscious process within the mind of the subject.

Whereas, in the case of spontaneous and induced suggestion, the limits are by no means easy to determine (a fact which to some extent justifies the confusion), in the case of reflective suggestion, on the other hand, it is possible to isolate suggestibility.

By suitable exercises (the use of Chevreul's pendulum, Abramowsky's experiments,[1] etc.), we can measure this suggestibility while using the same principles as Binet. But the nature of the exercises must be entirely

[1] See Part II, Chapter VIII.

modified. Like Binet, we may denote an individual's average suggestibility by the fraction $\frac{1}{S}$. We then examine this person in various emotional states, in a condition of slight hypnosis, etc., measuring by the method of averages the influence of these different factors, denominated $f_1, f_2, f_3, \ldots f_n$. Thus the formula of suggestibility in the given circumstances would be:

$$S = \frac{f_1 \times f_2 \times f_3 \ldots \times f_n}{s}.$$

It would likewise be interesting to study the variations in suggestibility according to age and sex. Each age, for example, might have a mean coefficient of suggestibility $\frac{1}{\Sigma}$ which would be a standard of comparison for the individual suggestibility $\frac{1}{S}$.

Suggestibility, in the sense we give to the term, is unquestionably related to the sensitiveness and to the plasticity of the nervous system. In children suggestibility, like acceptivity, is unquestionably superior to the same faculty in the adult. But whereas acceptivity is a source of weakness, and must be combatted, suggestibility is a source of strength, and must be fostered. If there be a tendency for the *physical conditions* on which suggestibility depends to grow less favourable as age advances, we must, by special training (in collection, contention, and autohypnosis), encourage the *mental* conditions which will reinforce suggestibility. By cultivating this faculty, while endeavouring to combat acceptivity, we prepare the subject to carry out beneficial autosuggestions and to repress those that are of a noxious character.

So great is the power of words, that it suffices to give the same name to two things which are quite different and often opposed, to give the same name to acceptivity and suggestibility, for the discredit which justly attaches to the former to be unjustly transferred to the latter.

It is largely owing to this confusion that public opinion has as a rule taken exception to educative suggestion. Boirac, in his *Psychologie inconnu*,[1] tells us he would speak of the use of suggestion in mental orthopædics, "were it not that this particular order of applications, inaugurated in our days by Dr. Bérillon, still seems to be generally discountenanced."

In truth, suggestion should be utilized, not merely for the orthopædics of the mind, but likewise for the normal training of the mind. We shall return to this question at some length in Chapter VII. We are content, for the moment, to point out that the educationist, who must miss no chances, will turn to the best possible account even the acceptivity, the passivity, the mental plasticity if you will, which is at its maximum in the child.

He is aware that children readily accept ideas and transform them into suggestions. He will therefore be careful to suggest those ideas only that are healthy and beneficial. Nay more, as the young intelligence awakens, he will turn passivity to account in order to counteract passivity. He will strive more and more to make the child accept the idea, that no idea is to be accepted without reflection and without control. At the same time he will teach the child to make deliberate use of suggestion, to find the material of suggestion for itself. Having made the best possible use of the child's acceptivity, he

[1] Alcan, Paris, 1908. English translation by Dudley Wright, Psychic Science, Rider, London, 1918.

will proceed to bring about the progressive atrophy of the faculty. Having employed acceptivity to aid suggestibility, he will employ autosuggestion to destroy acceptivity. Thus acceptivity will have played the part of those clay moulds which are used for the casting of bronze statues.

CHAPTER SIX

A CONTRIBUTION TO THE THEORY OF HYPNOSIS

THE phenomena comprised under the general name of hypnosis present two aspects, physiological and psychological. In the actual state of our knowledge, a psychological description can be carried further than a physiological description. "The theories which are termed psychological," writes Claparède with perfect justice, "have the great advantage of permitting a far more detailed explanation, a closer and more systematic analysis. If, on the other hand, we attempt to use objective phraseology, when we have spoken of cortical inhibition, of the stagnation of neurocymes, and of the rupture of synapses, we have said practically all that there is to say. There are still too many gaps in our knowledge of the physiology of the brain. The attempt to reconstruct hypnosis in physiological concepts is perhaps to-day almost as chimerical as would be the attempt to reproduce the delicate traceries of the Louvre with the clumsy materials in a child's box of toy bricks. As for the eminent architects who have vainly essayed the first-named reconstruction, they must e'en console themselves with the reflection that their failure has been due to the circumstances of the case, and not to their own incapacity."[1]

Contemporary philosophy, breaking away from the

[1] Claparède et Baade, Recherches expérimentales sur quelques processus psychiques simples dans un cas d'hypnose, Kündig, Geneva, and Archives des psychologie, 1909.

traditions of Spinoza and Leibnitz, tends increasingly to invalidate the hypothesis of psychophysical parallelism. It would seem that we are hardly justified in saying that every physiological fact is expressible in psychological terminology, and conversely. Conceivably, of course, hypnosis is the outcome of purely physiological causes, which must be elucidated on the physiological plane. But in my own view, this does not hold good. I consider that the very production of hypnosis can be expounded in psychological terms (without prejudice to the concomitant physiological phenomena).

We have described under the name of *hypnosis*,[1] deliberately chosen, states of somnolence which are distinguishable from ordinary drowsiness by their mode of production. We found, in fact, that the originator of these conditions was the immobilization of the attention, either by fixation (luminous point, noise of falling water), or by seesaw (lullaby, regular rhythm). From the difference in the mode of production of the condition there results a peculiar modification of the attention during the condition itself. To this modification we have given the name of *contention*. The slighter degrees of hypnosis, the only ones which have been hitherto described in the present work, are not followed by amnesia. They leave no gap in the consciousness, and the contention which characterizes them is a phenomenon of introspection—as anyone can perceive for himself. In this state, a minimum of effort suffices to retain an idea in the centre of mental vision; comparative mental immobility exists. Contention, as we have said, is a psychological equivalent of voluntary attention, minus effort.

[1] Part II, Chapter V.

Now, when the stimulus which has produced the hypnosis is prolonged, the somnolence grows deeper and deeper, and may culminate in sleep. This is *profound hypnosis* or *induced sleep*. The passage from somnolence to sleep is effected by insensible transitions. The difference between the two states is one of degree merely, not of kind.

1. Let us first consider the *production* of profound hypnosis. For this, practitioners are agreed in utilizing as a preliminary the immobilization of the attention. The commonest method is to direct the patient to fix his gaze on the practitioner's eyes or on some luminous point.

This sustained attention is no more than a means for the production of relaxation, which, as we have explained when speaking of slight hypnosis, is indispensable to the oncoming of sleep. Fatigue of the attention favours the relaxation, and this explains certain details in the technique of Braid, the founder of hypnotism. He writes: "A patient may be hypnotized by keeping the eyes fixed in *any* direction. It occurs most *slowly* and *feebly* when the eyes are directed straight forward, and most *rapidly* and *intensely* when they can be maintained in the position of a double internal and upward squint."[1]

Bérillon has realized that sustained attention is merely a means to an end, and that relaxation is the end. He

[1] James Braid, Neurypnology, Chapter II, Churchill, London, and Black, Edinburgh, 1843. The passage will be found on p. 115 of the most convenient work on Braid's life and writings, Waite, Braid on Hypnotism, Redway, London, 1899.

actually invites the subject to relaxation as soon as a certain degree of fatigue has resulted from the immobilization of the attention. He writes: "Instead of asking the subject, as previously, to fix his eyes on some point close at hand, I invite him to look straight in front of him, to look out into the infinite. My sole object in so doing is to secure complete relaxation from any accommodative effort. The subject's aspect soon shows that he has become utterly indifferent to everything that is going on around him. He is, therefore, in the state of uninterestedness favourable to sleep. The period of going-to-sleep is drawing to a close; sleep is imminent; and upon the slightest inducement, in obedience to the law of least effort, the subject's eyelids will close and he will fall asleep."[1]

Bernheim, who affirms that "suggestion is the key to all the problems of hypnosis," constructs a theory which is at once too simple and too systematic. He overlooks the indubitable rôle of immobilization of the attention. Nevertheless, his demonstration that suggestion can produce hypnosis unaided does not conflict with the foregoing observations, for suggestion presupposes the fixation of the attention on an idea; and consequently every suggestion, at the moment of formulation, is accompanied by an immobilization of the attention. The two actions supplement one another, the fixation by an idea replaces the fixation by a luminous point.

There is one form of induced sleep which does not presuppose the immobilization of the attention. When a subject is plunged into profound hypnosis, brought about by one of the ordinary methods, we may propose

[1] Bérillon, Théorie psychomécanique de l'hypnotisme. Revue de l'hypnotisme.

to him the following posthypnotic suggestion: "Every time that I touch your right shoulder," or "every time I show you a card on which is inscribed the word 'sleep' " (the precise formula is indifferent), "you will sleep as soundly as you are sleeping at this moment." These accesses of sleep due to posthypnotic suggestion will be the result of pure suggestion, without any antecedent immobilization of the attention. But we must not forget that the first sleep has been induced by one of the customary methods. The subject to whom we suggest, when he is asleep, that he will subsequently sleep in like manner, may perhaps reproduce by pure suggestion the immobilization of the attention which he has previously experienced.

Coué, who does not share Bernheim's exclusivism, accepts the existence of the two methods. We have just seen that if we set out from the immobilization of the attention as a principle, the two procedures are closely akin. Hence we must not be astonished at the likeness of the results. Coué notes the likeness without attempting to explain it. Here is his definition of hypnotic sleep:

"We may define it thus. Hypnotic sleep is sleep induced by an artificial cause (narcotic drugs excluded), such as the conscious or unconscious fixation of a more or less luminous object, or the use of suggestion or autosuggestion.

"Although the causes are different, the sleep appears to be the same in the two cases, and this sleep, though extremely restful, is in my opinion very different from ordinary sleep."[1]

[1] Coué, Le sommeil hypnotique et ses rapports avec la suggestion, Bulletin Ecole de Nancy, 1914.

2. What are the psychological *characters* of this peculiar sleep? If Coué affirms it to be "very different from ordinary sleep," this is not because he ignores the kinship between the two, a kinship which is far closer than most people imagine. But the first Nancy School was prone to dwell on the traits common to the two conditions, and it is therefore natural and justifiable that Coué should emphasize the differences.

From the days of Liébault onwards, the authorities of the first Nancy School followed by several other specialists and notably by Vogt and Forel, drawing attention to the likenesses, showed that, in general, both states facilitate suggestion; that catalepsy can be induced in natural sleep (Liébault); that the intellection of the words uttered by bystanders is not completely abolished during natural sleep. As an example of the last statement, it may be pointed out that one who snores will often stop snoring when told to do so.

Speaking generally, the authors who, with Bernheim, regard suggestion as the cause of hypnotic sleep, naturally tend to identify that condition with normal sleep. But, to consider the matter without prejudice, this identification must not be pushed to an extreme. Claparède, who has not committed himself to any theory of hypnotism, is an impartial judge. He writes:

"Let us make it perfectly clear *what* we are suggesting when we hypnotize. If we say to the patient, 'Sleep!' why does he not pass into ordinary slumber? Unless we agree that hypnosis is the same thing as normal sleep (and we have already refuted this hypothesis), the formula of 'suggested sleep' is insufficient to account for the phenomena. If we wish to maintain that hypnosis is due to suggestion, we have to admit that the very

fact of putting anyone to sleep by suggestion gives the sleep a peculiar character. The question then arises, *By what mechanism does this peculiar character originate?*'' [1]

The question is pertinent. The present writer thinks he can provide the elements of an answer. Hypnosis *may* be due to suggestion, but the very fact of suggestion presupposes the immobilization of the attention, an immobilization which is therefore common to all the methods for producing hypnosis, and wherein will be found the real réason for the peculiar characteristics of this condition.

Profound hypnosis exhibits in an intensified form the distinctive traits of slight hypnosis, in which the subject experiences a sense of vacancy, of mental immobility, giving rise to *contention*. Now we think we have been able to explain these characters as the outcome of the preliminary immobilization of the attention (Part II, Chapter V). The same cause is present here, but it is intensified. The idea of mental immobility,[2] as happens with any idea that is in the mind when sleep begins, dominates the whole of the sleep. The subject inevitably accepts a suggestion of mental immobility, and this suffices to explain the chief psychological differences between hypnotic sleep and normal sleep.

[1] Claparède, Interprétation psychologique de l'hypnose, reprinted from the Journal für Psychologie und Neurologie, Barth, Leipzig.

[2] Cf. Carl Picht, Hypnose, Suggestion und Erziehung, Klinkhardt, Leipzig, 1913. According to Picht, hypnotic sleep differs from ordinary sleep in this respect, that the former is the outcome of a concentration, whereas the latter is the outcome of a dispersion, of the attention.

Can we prove the existence, during profound hypnosis, of this (comparative) mental immobility, of the sensation of mental vacancy which accompanies it, and of the contention which is their result?

"It is generally agreed," writes Claparède, "that concentration of the attention exists during hypnosis. But I am not aware that any experiments have hitherto been undertaken for the verification of this hypothesis, and in order to ascertain the precise nature of the modification of the attention."[1]

Claparède has himself organized a series of experiments to explore the psychology of the hypnotized subject. His results, considered by themselves, do not seem to furnish an answer to the foregoing question. But when we juxtapose them with what introspection reveals concerning contention, they seem to throw much light on the matter, and to justify our hypothesis.

Here are the leading results, as far as they bear on the problem:

a. "Hypnosis tends to slacken associative reactions. . . . We must note, however, that while this is true on the average, certain associative acts may take place under hypnosis just as rapidly as in the waking state. This shows that the inhibitory theory is inadequate. Whilst associative inhibition is favoured by the state of hypnosis, it does not constitute that state. . . .

b. "If we examine Madame Bul's associative activity, not when she is performing an experiment, but when she is left to her own devices, what do we note? Absolute passivity. . . . Left to herself, Madame Bul says 'My mind is a blank'; she is indifferent to everything.

[1] Interprétation psychologique de l'hypnose.

She seems to have lost that constant concern about the present moment and the moment which is just coming, that concern which is the mainspring of all our actions and all our thoughts.[1]

"In Madame Bul, at any rate, the hypnotic state was essentially characterized by *a suspension of the function of initiative.* This conclusion has been drawn by other observers. We have seen that several authors, and Wundt in especial, characterize hypnosis by the suspension of voluntary activity.

c. "The power of adding numbers together is not during hypnosis appreciably different from the same subject's power during the waking state."[2]

"What are termed the *intellectual* faculties seem to be little if at all affected."[3]

The juxtaposition of these observations is most instructive. We learn from it that two apparently contradictory phenomena are present in hypnosis:

1. Voluntary activity is suspended.
2. What are termed the intellectual faculties appear to be little if at all affected.

This seems very remarkable. *The use of the intellectual faculties normally presupposes the working of voluntary attention; now here voluntary activity is suspended, and yet the intellectual faculties are none the worse.* But the apparent contradiction disappears if we admit that hypnosis is characterized by a modification of the attention,

[1] Cf. Beaunis: "When we ask a hypnotized subject, as I have often done, 'What are you thinking about?' the almost invariable answer is, 'Nothing.'—We have here a veritable condition of inertia, or rather one of intellectual repose."

[2] Claparède and Baade, op. cit.

[3] Claparède, Interprétation psychologique de l'hypnose.

namely, contention, which is *the psychological equivalent of voluntary attention, minus effort.*[1]

Furthermore, we have just seen that, according to the hypnotized subject's own statements, profound hypnosis is characterized by a sensation of mental vacancy.

We have thus verified the hypothesis that there is no essential difference between profound hypnosis and what we have termed slight hypnosis. We are therefore justified in applying the term hypnosis to both conditions.

One point may still seem obscure. The foregoing explanation appears to ignore one of the essential characteristics of classical hypnotism, namely, the rapport between the operator and the hypnotized subject, so that the subject, despite his sleep, understands the words of the operator.

This rapport presupposes that there shall be an operator. But hypnosis, as described in this book, does not necessarily require a hypnotizer. When I put myself to sleep by autosuggestion, by voluntary autohypnosis, or when I am sent to sleep by a soothing rhythm, there is hypnosis, but there is no hypnotizer.

In hypnosis of the classical type there is a hypnotizer, and throughout the hypnotic sleep the subject's mind is obsessed by the personality of this hypnotizer. If we recall the law that sleep is dominated by the obsessive idea or ideas which were in the mind at the moment of

[1] From the physiological standpoint, catalepsy is a pendant to contention, although it is a less constant character of hypnosis. We might say that *contention is a catalepsy of the attention.* In contention, the muscles of attention do their work without effort.

going to sleep, we shall realize that this obsessive presence of the hypnotizer may serve to explain the maintenance of communication between hypnotizer and subject. When we fall asleep pondering an unsolved problem, we give free rein during sleep to all the ideas which are more or less intimately connected with the problem, and without the facility given to the flow of these ideas the solution of the problem during sleep would be impossible. In like manner, during profound induced hypnosis, the subject's mind remains open to everything connected with the hypnotizer, and to his voice in especial. The mother who goes to sleep with her thoughts full of her child, and who wakens at the child's least cry, furnishes us with an example which is not essentially different from that of the hypnotized subject recognizing the voice of the practitioner.

In a word, the fundamental characteristic of hypnosis is a peculiar modification of attention, i. e. what we have named *contention*.

If hypnosis increases suggestibility, this may be dependent on various features of hypnosis (features which are in part common to hypnosis and to ordinary sleep); but for the most part it is due to contention, which annuls voluntary effort, a condition unfavourable to suggestion, while maintaining attention, a condition above all others indispensable to suggestion.

As for the apparent contradictions pointed out in Part III, Chapter I, where it was shown that suggestibility seems now increased now diminished by hypnosis, these contradictions vanish, so I believe, as soon as acceptivity is carefully distinguished from suggestibility properly so called. (See the preceding chapter.)

We have to admit that, as a rule, and probably in all cases, hypnosis is characterized by increased suggestibility. But it is not necessarily characterized by increased acceptivity.

Having learned the nature and the true significance of profound hypnosis, it remains to ask what are the best ways of inducing the condition. We wish to induce it easily, and we wish it to be fruitful when induced.

1. When we speak of the immobilization of the attention, our language is extremely abstract. There is not only one kind of attention. There are visual attention, auditory attention, mental attention, etc. A completer result will be obtained if we can immobilize them all simultaneously. (By occupying one, we tend to quiet the others, and may thus bring about a sufficient degree of immobilization.) We may engage the various forms of attention at one and the same time, appealing to sight by a luminous point, to hearing by a soothing and monotonous voice, to touch by rhythmic passes, and to the mind by the idea of sleep. Let us ignore the question whether the passes, over and above their effect upon the attention, have the peculiar physical action ascribed to them by the magnetizers.

2. The suggestions we have to propose will be more likely to be efficacious if we employ methods tending to establish a close rapport between operator and subject. Such methods are those which tend to make the operator's presence a positive obsession for the subject. For instance, we shall appeal to sight with a luminous object, and the best will be for this object to be held by the hypnotizer, who will impress upon it a rhythmic movement. The voice, and passes, are additional means for

emphasizing the hypnotizer's personality. In his ordinary practice, Coué uses methods which satisfy these requirements. Here is his own account of them.

"You move a luminous object to and fro before the subject's eyes, requesting him to follow this object with his eyes, but without turning his head. Meanwhile you make to him the following suggestions: 'Think well that you are going to sleep; as you follow the moving object with your eyes, you feel a lethargy stealing over you; your arms, your legs, become heavy; your whole frame grows heavy; your eyelids are heavy, they grow heavier and heavier, they are like lead, you find it more and more difficult to keep your eyes open. Your sight is becoming obscured, your eyes are watering, you can hardly distinguish anything in the room, sleep begins to overpower you. I shall slowly count up to twenty. As I count, the longing to sleep will steadily increase. Before I reach twenty, your eyes will close and you will be sound asleep.'

"In most cases, everything happens exactly as you have said; and by the time you pronounce twenty, the subject is asleep. If his eyes are not yet closed, say to him in a commanding tone, 'Shut your eyes! Sleep!' and he instantly closes his eyes and goes to sleep.

"To make the sleep more profound you say: 'Now you are asleep, sound asleep, and as I tell you that you are sound asleep, you do in fact feel that your slumber becomes deep, very deep, deeper than it has ever been before.' This word 'deep,' repeated in such a fashion, acts on the subject's mind like the drops of water which in the end hollow out the stone."[1]

[1] Coué, Le sommeil hypnotique et ses rapports avec la suggestion.

But in general, as we have said, the Nancy method does not involve the induction of profound hypnosis. This latter condition would seem to be chiefly valuable in cases where the subject is maladroit in the use of auto-suggestion, above all when he cannot learn to avoid making efforts of the will. Profound hypnosis suspends the voluntary activity which is impairing the chances of success.

CHAPTER SEVEN

SUGGESTION IN THE EDUCATION OF CHILDREN [1]

SUGGESTION is a psychophysiological function which exists in everyone. It can therefore be trained in everyone. No reader who has carefully followed the exposition of data and reasoning throughout the preceding pages can fail to understand how baseless are all the objections that have been made to the use of suggestive methods in the education of children. Induced suggestion is not a violation of the subject's individuality; it is a means of training the subject's powers of autosuggestion. Moreover, only in connection with profound hypnosis could the idea of such a violation being effected possibly arise. Now, we have seen that for the adult the

[1] There have been precursors in this field of educative suggestion. I may mention the following:

J. M. Guyau, Education et Hérédité, Paris, 1889 (English translation, Education and Heredity, Walter Scott, London, 1891), seems to have inaugurated the idea.

Walter Rose, Die hypnotische Erziehung der Kinder, Berlin, 1898, refers to suggestion for the inhibition of instincts such as cleptomania and lying. (He looks upon the latter as instinctive and as hereditarily transmitted in modern society.) He speaks also of the development of new instincts by suggestion.

The scholastic outlook in especial is voiced by two writers in the Zeitschrift für Philosophie und Pädagogik. Horn contributes, Suggestion als pädagogischer Faktor, neue Bahnen (Heft 5, 1900). Rausch contributes, Die Suggestion im Dienste der Schule (Heft 4, 1901).

Carl Picht champions the views of Guyau and Rose. See his Hypnose Suggestion und Erziehung, Klinkhardt, Leipzig, 1913.

use of profound hypnosis is as a rule a subsidiary method. Still more is this true of children, whose suggestibility in the waking state is so extensive. Their high suggestibility is a reason for beginning the training of autosuggestion in early childhood.

This training, far from reducing the subject's energy, seems, in virtue of its peculiar mechanism, to enhance that energy; and it does so in the absence of any suggestions of a directly energizing character. Besides, not merely would it be a mistake to attempt to shield the child from all suggestive influences. The thing is an impossibility. If suggestive action be not exercised methodically, it will be exerted by chance, in the form of the countless spontaneous suggestions which daily life presents to the child's mind. When we take this suggestive action under our own guidance, we can ensure that it will be beneficent. When, on the other hand, we leave it to itself, it gives rise indifferently to good and to bad results, and it may eventuate in disaster.

Unreservedly, therefore, I agree with Herbert Parkyn's contention that the deliberate practice of autosuggestion should be taught to children in all our schools.

I would go further, and would say that autosuggestion ought to take a primary place in education. For by its use, not merely will the child learn self-control, not merely will he develop his physical energies and be helped to resist disease, but in addition he will be able to develop (in a degree hardly conceivable by those who have not seen the method applied) his working powers in all fields. He will learn how to obtain the maximum of results with a minimum of effort; he will acquire a method which will be a standby to him throughout life. In the intellectual sphere he will develop all his faculties,

and memory and attention above all. In especial he will learn to *like* his work. Furthermore, by suggestion, we are able to strive advantageously against the bad inclinations and other defects of childhood, most of which are indeed themselves to a greater or less degree the outcome of antecedent suggestions. It follows from these considerations that the suggestive method cannot properly be regarded as merely a minor weapon in the pedagogical armamentarium. It can be made the auxiliary of all training and of all instruction. To anyone who has practised educative suggestion, pedagogical treaties which systematically ignore this discipline seem built upon shifting sand. In such conditions, the dispute between the various complicated methods which claim to develop memory, attention, and interest, in children, resembles nothing so much as an interminable argument among persons in a hurry as to which is the quickest footpath, while they pay no attention to the railroad close at hand, to the train which could take them where they want to go in a tenth part of the time.

Doubtless when we are concerned with educating a child's tendencies, we must respect, as far as they are wholesome, all the most spontaneous tendencies he displays, all those which are a sign of his aptitudes and of his very nature. Here suggestion must be cautiously used. But many of the tastes, many of the tendencies, which seem natural to the child, are simply the outcome of spontaneous suggestions. Children's games, far from being in every case an expression of the child's deeper nature, are often purely imitative. As I had occasion to point out in an earlier chapter (Part I, Chapter VI), the same statement applies to young people's choice of a profession. In many cases, therefore, the rôle of sug-

gestion should be to eradicate the factitious tastes and tendencies of childhood. We shall be able to safeguard this practice by careful observation. Psychoanalysis, for example, is competent to reveal the genuinely original tendencies, and we shall respect these in so far as they are not harmful to the child, or do not promise to be harmful to it when it grows up.

The method of training suggestion which has been described in this book is applicable to children, but may be simplified in view of the great suggestibility of youthful subjects. The exercises with Chevreul's pendulum are especially useful for children. They may be modified by making them into a game. For instance, the bob of the pendulum may take the form of a bird which has to peck a piece of bread, or of a cat chasing a mouse, and so on. We can organize competitions. But in their simplest form, the exercises will be found sufficiently interesting to the great majority of children.

Quite apart from exercises, quite apart from any procedure which recalls therapeutic suggestion, it is possible, in large measure, to guide the suggestions that act on a child's mind. Thanks to a child's acceptivity, ideas which are frequently brought to its notice, ideas uttered by parents, teachers, and others in whom it has confidence, readily become implanted, and initiate suggestions. Consequently, when we are with children, we must scrupulously avoid doing and saying things which will initiate harmful suggestions. On the other hand, we should frequently repeat the ideas which are likely to be the starting-point of beneficial suggestions.

Guyau judiciously remarks[1] that it is extremely foolish, when a child has done wrong, to express our censure

[1] Op. cit.

in the form of a generalization such as, "What a greedy boy you are; what a liar; what a naughty child." So doing, we tend to determine the future. The child thus characterized looks upon itself as a glutton, as a born liar, and so on, and acts accordingly. It is far better policy to show great surprise that so good a child, one habitually truthful, etc., could have to-day made you believe that it was a liar, when you know perfectly well that it is nothing of the kind.[1]

A woman teacher in Geneva, who has attended my lectures at the Jean Jacques Rousseau Institute, practises on her pupils the following ingenious method of indirect suggestion. Every Monday, when the week's work begins, she writes on the blackboard the "resolution of the week." In a brief phrase this summarizes and aims at correcting some fault in conduct or in methods of work which has been epidemic during the previous week. The children copy the formula, and collectively take the good resolution. The results have been gratifying. I may add that this teacher, having grasped the significance of the law of reversed effort, has substituted for the formula first used, *I want to be* this or that, the formula, *I shall be* this or that. The effects of this substitution have been obvious.

From the earliest years of childhood, and unceasingly thereafter, we should, in word and deed, watch over the suggestions made to the child mind, and above all should

[1] Cf. Froebel: "We have to recognize that in many cases the teacher has himself made the child ill-conducted and vicious by attributing to it a bad intention in the committing of actions which were indeed regrettable, but which the child performed without realizing their true bearing, performed through lack of foresight, through heedlessness, or through want of judgment."

we be careful to avoid making any harmful suggestions. American manuals contain excellent observations on this subject. For instance, Herbert Parkyn writes:

"As a rule, parents pay little attention to the nurses they employ to look after their children. They employ Mary or Jane because she seems kind-hearted and can be hired cheap because ignorant—too ignorant, as a rule, to fill positions in which more money can be earned.

" Kindness is not all that is required to make a good nurse for a child; and if parents could fully realize a nurse's influence on their children they would employ only a speaker of good English, a woman with charming manners and good principles—a woman, in fact, who possesses the qualities they would like to see developed in their children. A nurse of this kind is cheap at any price. I venture to say that the time is not far distant when there will be regular training schools established for nurses for children, and that these nurses when properly qualified will draw larger salaries than the trained nurses from our hospitals. When this time comes, the training of the children who are to be candidates, subsequently, for the presidency of the republic, will not be left to ignorant Mary or Jane. If a nurse is to be employed at all, it will be a nurse who can give the child the best influences during the time he is receiving his first suggestions—the most impressionable time of a man's whole life.

"Not long ago I was riding in the same railway coach with a mother and her little girl. The child was sitting in the seat opposite to her mother, riding with her back towards the engine. Suddenly the mother said to her:

" 'Charlotte, come here and sit beside me. It will make you sick if you ride backward.'

"A suggestion like this placed in the mind of a child is sufficient to influence her the rest of her life while riding in any class of vehicle. It will do a great deal to spoil her enjoyment of travelling, because she will fuss over securing a seat facing the direction in which she is travelling, and if she be forced by circumstances to ride backward, the autosuggestion arising from the old suggestion given by the mother will be sufficient to make her miserable if not actually sick.

"There is no reason on earth why a person should not ride backward as comfortably as any other way. Still, I have seen women standing in a street car refuse to accept a seat offered them, the excuse being:

" 'Thank you! I prefer to stand. It makes me sick to ride backward.'

"Poor things, they are made miserable by a common superstition or a suggestion given to them in childhood!

"I have selected this illustration because the superstition or belief is a very common one, but there are thousands of similar absurdities prevalent among the masses to make life fussy or unhappy.

"Let us arise, then, and see what we can do by new autosuggestions to stamp out the old absurd notions, first in ourselves, and then, by precept and practice, endeavour to assist our fellow men to free themselves from their self-imposed burdens."[1]

Where health is concerned, we cannot be too careful about children, both as to what we say in their presence, and as to what we allow them to see. Not merely must we spare children the sight of illnesses which would impress their imagination; but before children even more than before adults we must scrupulously avoid

[1] Op. cit., pp. 47-9.

speaking of illness. We must shun the small change of conversation in which, when we have exhausted the subject of the weather, we pass on to speak of health, that is to say of disease. I mean the sort of talk wherein, having reviewed the headaches, the constipations, the nose-bleedings, and the toothaches, of our own interesting personality, we proceed to discuss the rheumatisms, the chronic bronchitis, and the stitches of our uncles and aunts, our male and female cousins, down to the twenty-fifth degree of family relationship. Next comes the list of sudden deaths or rapidly fatal illnesses in our own street and our own quarter of the town. And we finish off with philosophical conclusions in the style of Joseph Prudhomme and Monsieur Perrichon anent our mortal frailty and the numberless enemies ever on the watch for a chance of destroying our precious health.

A reasonable code of good manners would forbid as a piece of rudeness the asking of people how they are; and still more the replying to such a question by saying that we don't feel at all well, and insisting on the fact with unction. Conversations of the type just described do harm to those who talk in this way; but, after all, that is their own affair. It is, however, a serious matter, when people speak freely of illness in the presence of children who are all eyes and ears to absorb what they see and hear.

Everything which tends to make illness impressive—the solemn medical attendant who comes in a tall hat, the solemn medicines in variously coloured phials, and the like—all such pomp and circumstance should be removed as far as possible from the sight and hearing of children. It is equally important that we should hide from a child any anxiety we may feel as to the condition

of its own health. These precepts are elementary for anyone who understands the suggestibility of the youthful mind. Let me quote once more from another American writer:

"One reason why we have such poor health is because we have been steeped in poor-health thought from infancy. We have been saturated with the idea that pain, physical suffering, and disease are a part of life; necessary evils which cannot be avoided. We have had it so instilled into us that robust health is the exception and could not be expected to be the rule, that we have come to accept this unfortunate condition of things as a sort of fate from which we cannot get away.

"The child hears so much sick talk, is cautioned so much about the dangers of catching all sorts of diseases, that he grows up with the conviction that physical discords, aches, pains, all discomfort and suffering, are a necessary part of his existence, that at any time disease is liable to overtake him and ruin his happiness and thwart his career.

"Think of what the opposite training would do for the child; if he were taught that health is the everlasting fact and that disease is but the manifestation of the absence of harmony! Think what it would mean to him if he were trained to believe that abounding health, rich, full, complete, instead of sickness, that certainty instead of uncertainty, were his birthright! Think what it would mean for him to *expect* this during all his growing years, instead of building into his consciousness the opposite, instead of being saturated with the sick thought and constantly being cautioned against disease and the danger of contracting it!"[1]

[1] O. S. Marden, op. cit., pp. 255-6.

But in that case, it may be objected, we should have to be ever on the watch lest we should influence for evil the children by whom we are surrounded. Despite the best will in the world, we shall err in this respect a hundred times a day.

Certainly we must avoid undue exaggeration concerning these inevitable errors. But for the very reason that such blunders will often elude our most watchful attention, it will be well to apply to children the methods of suggestive therapeutics. By speech, gesture, and example, we may often give them good suggestions; but we shall not fail, from time to time, to give them bad ones in addition. The rôle of methodical suggestion will be to reinforce the former and to neutralize the latter.

In addition to the methods above described, there is one which is peculiarly suitable for children. It makes use of natural sleep, when the subconscious remains awake, just as it remains awake in induced sleep. Coué recommends parents to proceed as follows:

"As soon as the child has gone to sleep, one of the parents goes very quietly into the bedroom and up to the bed. A hand is slowly and gently laid on the child's forehead. Should the child stir, and seem about to wake up, the parent says in a low tone, 'Sleep, go on sleeping, sleep soundly,' repeating the phrases until the child is sound asleep once more. Then the parent, still in the same slow and quiet tones, reiterates all the improvements desirable in the child, whether from the point of view of health, sleep, work, application, conduct, or the like. When this has been done, the parent withdraws, still taking the utmost care not to wake the child."[1]

[1] Op. cit., p. 26.

I should point out that, to be really fruitful, this simple method should be put in practice every evening without exception. Coué is in the habit of saying that a child should have suggestion every day, just as every day it has a cup of milk or a cup of cocoa for breakfast. The parents should make it part of their routine. In such conditions, the results are sometimes so remarkable that parents to whom I have advised the procedure have at the end of a few weeks told me that they were positively "alarmed" by the marvels that had ensued. I may add that if the parents set to work awkwardly at first, no great harm will result, since suggestion can undo whatever suggestion has done. Should an error be made, it will be easy to correct it.

CHAPTER EIGHT

GENERAL METHODS OF APPLICATION

INDUCED suggestion, as described in this work, is susceptible of very wide applications. It is upon these that we wish to insist in conclusion.

1. From the point of view of the *operators,* it can be generalized in this sense, that the method can be entrusted to practically everyone.

This is possible, in the first place, because it is free from the dangers so frequently ascribed to it. In essence, it is in no respects the taking possession of one individuality by another. The practitioner is not a master who issues orders, but a guide who makes proposals. Moreover, only in connection with induced sleep could there be any reason to dread that such a state of dependence might arise; but we have learned that, in the great majority of instances, induced sleep is superfluous. Again, dependence is not even one of the characteristics of the special state we are considering, for obedience to the practitioner's orders, far from being always increased, is not infrequently diminished. When dependence ensues, it would appear to arise solely out of autosuggestion, as when the subject is afraid that it will arise. Herein we find an additional reason for generalizing the practice and the theory of autosuggestion, to the end that a knowledge of the practice may be widely diffused, in order to destroy superstitions concerning

hypnotism and its dangers—superstitions upon which such dangers as exist do actually depend.

Yet another reason for generalizing the practice of induced suggestion is the simplicity of the method. The only requisites are the performance of a few elementary exercises, a moment of muscular and mental relaxation, in conjunction with perseverance and regularity. Thus without having recourse to the classical methods of hypnotic suggestion, we obtain results more remarkable than those secured by earlier hypnotists. So simple is the procedure, that few can fail to master it. For the rest, it will not bear its full fruit unless we consider it as a training of the subject's power of autosuggestion. The practitioner's ideal must be that of every genuine teacher, which is to render the pupil capable in the end of doing without a teacher. Herein we see a further motive for rejecting the hypothesis that induced suggestion, as we advocate it, involves social dangers. If we admit that unconscientious suggesters may avail themselves of a method which tends to enslave their subjects, not to liberate them, such suggesters will not secure the results derivable from the method described in the present work, seeing that one of the essential principles of our method is to make the subject understand the mechanism of autosuggestion, to give the pupil the key. It is above all on this account that the method is so successful, and is able to furnish results far superior to those of methods based on heterosuggestion. Nor need this surprise us. Persons who appeal to autosuggestion display a fuller knowledge of the peculiarities of the mind, and it is by understanding and applying the laws of nature that we can obtain the best results. Inevitably in such cases there is a struggle for existence between

the rival methods. That which produces the best results will survive.

When induced suggestion, as above described, has to be employed for the relief of some physical ailment, the method is available to all. There is nothing distinctively medical about it, and there is no reason why it should remain a monopoly of medical practitioners. It can be used by all parents and by all educationists for the benefit of their children and their pupils. Its use does not require specialized knowledge of medicine. This follows from the law of subconscious teleology. We have merely to suggest the idea of cure, and the subconscious makes it its business to discover the physiological means for realizing the cure, without either the operator or the subject requiring to know what these means are.

2. Turning to the outlook of the *subjects,* we may say that for them also the method can be generalized; with the exception of a small percentage of abnormal individuals, it is suitable for everyone's use. It is applicable to all persons and to all ages. No temperament will prove permanently refractory. There are none in whom suggestion is peculiarly liable to induce unfavourable results.

3. Turning, finally, to consider the *cases* suitable for suggestive treatment, the possibilities of wide application are no less obvious. Bernheim drew a line between functional and organic maladies, but for us the limits of suitable cases have been greatly extended. Great numbers of organic affections, even those which physical methods of treatment have failed to relieve, have yielded to the power of suggestion. In the present state of our knowledge it is impossible to say what are the limits of that power. The remarkable results secured in recent

years have completely upset the ideas formerly entertained, and we have a right to expect yet further advances. The inference is that suggestion may be tried and ought to be tried in every case.

Nay more. We are justified in affirming that suggestive treatment will at least give some relief in every case in which the patient remains conscious. Let us suppose, for the sake of argument, that there is some organic illness in which suggestion is absolutely powerless. If the patient's mind be dominated by the idea that he is suffering from such an illness, there will inevitably ensue (above all if the illness be attended by pain) a spontaneous suggestion which will aggravate the morbid state. Attention, mingled with emotion, returns despite itself to the idea of illness, in everyone who knows himself to be ill, and still more in anyone who actually feels himself to be ill. Suggestion is an inevitable sequel. The consequence is that in every actual case of illness there are two elements, a primary element which is the direct issue of the malady, and a secondary element which is the outcome of autosuggestion. Now if, by hypothesis, the primary element be rebellious to suggestive treatment, the secondary element cannot fail to be amenable to suggestive treatment. Hence suggestive treatment will bring relief in all cases.

We may add that even in cases for which the use of physical methods of treatment is regarded as indispensable or advantageous, there will still be plenty of scope for suggestive treatment as an auxiliary. Suggestion can make it easier for the patient to take distasteful medicines; it can help to overcome the undesirable effects of certain drugs; it can be used to induce anæsthesia when painful manipulations and operations are necessary.

I do not wish to advise every doctor to make a systematic use of direct suggestion. When a medical adviser proposes the use of suggestion, the patient may accept the method with very little confidence in the result. On the other hand, when a patient spontaneously applies to a specialist in suggestion, he probably does so, in the great majority of instances, because at bottom he expects satisfactory results. In such conditions the soil is favourable, and there is a much better chance of complete success. The patient consulting a doctor who does not usually practise as a suggester, expects a prescription, and ipso facto has some confidence in this prescription. The doctor must take advantage of such a state of mind, and must use the prescription as the vehicle for indirect suggestion. Coué, with his customary psychological acumen, explains the matter as follows:

"If a doctor, after examining his patient, writes a prescription and hands it over without comment, the drugs thus ordered are not likely to do much good. But when the practitioner explains that this medicine or that must be taken in such or such conditions and it will produce such or such effects, the results thus described will rarely fail to occur. . . . In my opinion, whenever a patient consults a doctor, the latter should always order some drug or other, even if drugs should not be really indicated. For the ordinary patient goes to see a doctor in the expectation that the doctor will prescribe a drug which will cure. Only in exceptional cases does the patient know that hygienic measures are of the first importance, that he will be cured by following a regimen. These seem to him trifling matters. What he wants is a bottle of medicine.

"Should the doctor merely prescribe a regimen and

fail to order any medicine, the patient is likely to be discontented. He will be apt to say to himself that since he has not been given any medicine he has wasted his time. Very often he will seek other advice. I consider, therefore, that the doctor should always prescribe some medicine for his patient. He should avoid ordering advertised specifics, whose chief value is derived from the very fact of wide advertisement. He should write his own prescriptions, for the patient will have far more confidence in these than in X's pills or Y's powders, which can be bought from any druggist without a prescription.''[1]

In this manner suggestion can be methodically employed without the patient being aware of the fact. A knowledge of the methods of indirect suggestion is invaluable to educationists and to parents no less than to medical practitioners. We may add that in these cases we depend less upon knowledge than upon tact and upon psychological insight.

[1] Op. cit., pp. 18 and 19.

CONCLUSION

SUGGESTION AND THE WILL

SUGGESTION, therefore, is nothing more than autosuggestion. It is an active process which goes on in the interior of the individual, and whose starting-point is an idea. If we consider these characters alone, we may be inclined to confound suggestion with the will. But whereas a voluntary act is one of which consciousness is aware, the mechanism of a suggested act remains essentially subconscious. With this difference in character there is associated a practical difference. Suggestion (autosuggestion) does not bear its full fruit except on condition that it be not confounded with the will.

In the psychology of the schools it is customary to distinguish three types of mental activity: instinct, habit, and the will. Suggestion is not reducible to any of these categories. It is an activity sui generis, and must henceforward be allotted its place in psychology side by side with the other three. Neither theoretically nor practically is it less important than these.

Suggestion enables us to control something within our organism which is independent of the action of the will, something to which we can never hope to issue direct commands. We thus reacquire a privilege which, according to Delbœuf,[1] we originally possessed in an earlier

[1] Delbœuf, De l'origine des effets curatifs de l'hypnotisme, Bulletin Académie Royale de Belgique, 1887.

stage of evolution. In those days the living being was fully aware of all that went on within. Owing to division of labour, its attention was increasingly directed outwards, and the supervision of the inner world was left to the subconscious. However this may be, suggestion seems to reëstablish the supervision, to reconquer a realm lost in the course of evolution, and to reconquer it without any detriment to subsequent gains. For whereas the will has no power to promote the development of suggestion, this latter, opening a path to the very centre of our being, can act on all our functions and all our faculties, and can promote the development of the will itself.

Suggestion, like the will, is a mode of activity dominated by a teleological principle; it represents a continuous adaptation of means to the attainment of a desired end. We can indicate the kinship between the will and suggestion and can simultaneously emphasize the difference between the two by saying that the teleology of the will is conscious whereas the teleology of suggestion is subconscious.[1]

The trend of contemporary psychology is to seek in the mind, at a lower level than that occupied by the fully conscious faculties, other forms of mental life which are deeper and less conspicuous.

In this respect, two contemporary movements are peculiarly significant.

[1] Instinct likewise works towards an end. But instinct, according to Hartmann's definition, is the conscious means for an unconscious (subconscious) end. Suggestion, on the other hand, is the subconscious means for a conscious end. The contrast is stated in general terms, finer shades being ignored.

In the affective sphere, Freud and the psychoanalysts have emphasized the existence of affective complexes, of sentiments and tendencies, belonging to the realm of the subconscious, and unceasingly determining our actions without our being aware of the fact. Psychoanalysis, bringing them to light, enables us to gain control over them, and thus to escape their tyranny.

On the other hand, *in the representative sphere,* Bergson has founded his philosophy upon the distinction between intelligence and intuition. The latter slumbers in the depths of our being. It seems to possess much of the knowledge which is of the greatest importance to life. By the study of intuition we are able to solve certain problems which we might never have been able to solve on purely intellectualist lines. Without pausing to consider the metaphysical consequences which Bergson draws from this distinction, let us take it as it stands, considering it purely from the psychological outlook, from which we think it is hardly open to objection.

Finally, the New Nancy School embodies a movement parallel to the two just named, but a movement *in the active sphere.* In this field, by the very nature of things, the investigator is primarily led towards action rather than towards theory. Such was the path followed by Coué. Hitherto the New Nancy School has failed to become aware of the true psychological significance and of the vast bearing of its own affirmations. Suggestion (autosuggestion) is to the will what the complex is to the sentiment and what intuition is to intelligence.

The three foregoing doctrines, mutually complementary, agree in indicating that in all the spheres of the psyche there exist deep and hidden strata. Far from

being inferior in point of value to the superficial strata, the deeper strata frequently yield us fruits which could never be secured from the surface consciousness.

Thus by three independent and parallel routes, contemporary psychology discloses the subconscious, and makes available its precious stores of mineral wealth. Coué, like Freud and Bergson, prefers to speak of the "unconscious" rather than of the "subconscious," choosing the former term precisely because he wishes to emphasize his view that the consciousness in question is not to be regarded as inferior to the superficial consciousness.

Furthermore, the term "unconscious" conveys the idea that the deeper psychological processes appear to be more or less independent one of another; that they seem to be dissociated; that they do not, as does the superficial consciousness, constitute a synthesis centring in the ego (the idea of synthesis being expressed by the prefix "con"). On the other hand, the term "unconscious" is inconvenient because it applies equally well to purely physiological processes, to reflex action, to mechanical responses to stimuli. If we employ it, we have always to specify when we are speaking of a psychological unconscious. But in my opinion the term "subconscious" can be precisely defined as the psychological unconscious. The word is already current in psychology, and if it be clearly defined no confusion can possibly arise.[1]

[1] It is essential that writers on these topics should come to a definite understanding in regard to the use of these words. Bernheim, in a recently published work (Automatisme et suggestion, Alcan, Paris, 1917), is frequently the victim of a confusion in terms. He identifies the "subconscious" with a "vague

We may say, then, that psychoanalysis, intuitionism (considered apart from all metaphysics), and the teachings of the New Nancy School, contribute to the same general movement. These three doctrines enable us to enter the subconscious, open ways for us into the hidden recesses of our being. Thereby they greatly enlarge our knowledge of ourselves, disclosing the causes of what we have hitherto known only as effects. Since knowledge is power, they increase our command of life. At the same time they meet the wishes of William James, who regretted the way in which we live only on the surface of things. Henceforward we can penetrate into the depths, and we are entitled to expect great results from these new possibilities.

The parallelism might be carried still further, especially as regards the distinction between the views of Bergson and the views of Coué. Just as the organic control rendered possible by suggestion seems to be the recovery of an ancient heritage which had been lost in the course of evolution, so the Bergsonian intuition is at its deepest roots identified with instinct. Intuition is not so much to be won by a new conquest as to be reconquered. If we have lost it in the past, it is because our attention has been more and more attracted by the needs of outward activity, demanding new adaptations.

Intelligence constitutes one of these adaptations. It

consciousness"; whereas he regards the "unconscious" as a priori "non psychological," and identifies it with "automatism." The consequence is that the phenomena of suggestion, not being automatic, are simply "conscious," and by very definition cannot be unconscious. By this paradox experiment is falsified and observation is distorted.

is the mode of knowledge which is applicable to crude matter, whereas intuition is the mode of knowledge which is applicable to life. Intuition is the primitive mode of knowledge, from which intelligence is derived by adaptation. That is why we can never arrive at intuition by way of intelligence, whereas we can pass from intuition to intelligence by following the path of differentiation which has been pursued by evolution.

Now there are identical relationships between suggestion and the will.

If this be so, we may sum up the distinction by saying that the will is the normal mode of acting on matter, on the external world, whereas suggestion is the normal mode of acting on ourselves quâ living beings. Experience confirms the hypothesis.

When we wish to act on the physical world we must seek to know the laws which regulate its mechanism, we must endeavour to elucidate the unending sequences of cause and effect. We are compelled to understand, consciously to grasp, the nexus of causality. The will, fully conscious, is at work.

But when we come to act on ourselves we can employ a very different method, that of suggestion. Here the saying, Who wills the end wills the means, is no longer valid. It suffices to *think* the end. Everything then ensues as if our subconscious were familiar with all the details of our physical and mental organism, and as if it could deduce from this knowledge the means necessary for realizing the proposed end. Here the end which has to be attained appears to find its own means, just as the poem which is to be born gives rise in the mind of the poet to the words fit for its expression.

But if we are living beings in whom teleology tends to

realize itself spontaneously, we are none the less parts of the material world, the world where mechanism reigns. Consequently, an action analogous to that which we exercise on the physical world, remains legitimate. Such an action is exerted in the ordinary practice of medicine.

It follows that medicine and suggestion are complementary, like a couple of forces acting in contrary directions and therefore unable to rival one another. Or we may say that the first acts from without, being centripetal. The second acts from within, being centrifugal. Though each taken alone is doubtless inadequate, by uniting they can realize the fable of the blind man and paralytic.

Suggestive practice, therefore, must not be looked upon as a chapter of medicine, any more than suggestion must be regarded as a special case of will. The two belong to distinct categories. Suggestive practice is not properly speaking a therapeutic method. With the work of the New Nancy School it passes from the medical to the pedagogical sphere. It does not so much consist of a descriptive science as of an education or reëducation of certain mental aptitudes and habits which human beings have been tending more and more to lose.

Modern times have been characterized by the conquest of the material world. It is therefore natural that, when we turn back to man, we should retain the habits of thought we have contracted in our prolonged intercourse with the physical universe. Such is the invariable method of conventional medicine. Thereby, however, it reaches no more than a part of the human being. It moves from without inwards, though there is just as much need that it should radiate from the centre to the

periphery. It has a wide knowledge of the effect of physical agents upon man, but we still have to learn the reaction of the human mind upon physical agents.

The work of modern science is a great achievement, but it is incomplete. For its completion a certain change is necessary both in outlook and method. As the philosopher Spir has well put it, "We are masters of nature externally alone, inwardly we are nature's slaves." Studying only too well all that surrounds us, we have forgotten our own personality, and now or never is the moment when we must put into practice the Socratic maxim "Know thyself." The doctrine of the New Nancy School, in conjunction with other doctrines of contemporary psychology, enables us to make a great advance in this knowledge.

GLOSSARY

Acceptation. The acceptance of an idea by the subconscious.

Acceptivity. The readiness with which the subconscious accepts an idea. (Readiness to accept heterosuggestion.)

Autosuggestion. The subconscious realization of an idea in more or less complete independence of heterosuggestion.

Censor, The, or The endopsychic censor. A figurative impersonation to denote the sum of repressive forces.

Collection. The state of outcropping of the subconscious resulting from a willed (but not voluntary) relaxation. (See **Relaxation,** below.)

Complex. A group of emotionally tinged ideas partially or entirely repressed. (Usual Definition of Psychoanalysts.) An integration of images, memories, sentiments, conscious and unconscious reasonings, interlacing one with another, and to all appearance inextricably intertangled (Baudouin).

Concentration. A state of autohypnosis and of persistent contention with one idea, the autohypnosis having been induced by the lulling influence of the idea on the mind.

Contention. Is a psychological equivalent of attention, minus effort. It is the state we attain to by means of collection (q.v.). Some writers term this state concentration, but see **Concentration.**

Derivation. See **Sublimation.**

Fascination. The capturing of the attention by some sensory phenomenon.

Fixed Idea. The ultimate degree of obsession.

Foreconscious. See **Preconscious.**

Hallucination. An imaginary sensation, one to which no objective reality corresponds.

Hallucination by Compromise. A hallucination suggested by the illusory interpretation of an objective reality.

Heterosuggestion. The subconscious realization of an idea suggested by another.
Also, the act of suggesting an idea to another.

Hypnosis. A general name for states of outcropping of the subconscious produced by immobilization of the attention, and for states of somnolence which are distinguishable from ordinary drowsiness by their mode of production.

Ideoreflex Process. The process by which an idea realizes itself or tends to realize itself in action. (It is to this that Baudouin limits the signification of the term suggestion.)

Obsession. The capturing of the attention by something purely subjective, an image, a memory, or an idea.

Outcropping of the Subconscious. The invasion of the normal waking consciousness by uprushes from the subconscious.

Passivity. See **Acceptivity.**

Preconscious. A region of the mind containing memory traces which can only be aroused by exceptionally strong stimuli or by special effort. (This region is transitional between consciousness and the subconscious. Usually spoken of by psychoanalysts as the "foreconscious.")

Relaxation. The release of mental tension, the cessation of attention and the suspension of inhibition, which favours the outcropping of the subconscious. This relaxation is the outcome of a decision of the will, but a decision in virtue of which the will abdicates

for a season. "Relaxation" is precisely this abdication.

Repression. The keeping from consciousness of mental processes that would be painful to it.

Schemata. Fragmentary or simplified equivalents of sensations, emotions, sentiments, memories, images and other mental states.

Subconscious. A region of the mind normally inaccessible to consciousness. (Usually spoken of by psychoanalysts as the "unconscious." See pp. 329 and 330.)

Sublimation. The employment of energy belonging to a primitive instinct in a new and derived, i. e. non-primitive, channel. E. g. the use of sexual energy in "intellectual" love or creative artistic work (Tansley). The process of enlisting the unconscious in the work that is available for social purposes (Lay).

Suggestibility. Readiness to realize a suggestion. (In Baudouin's use of the term—in more or less complete independence of heterosuggestion.) Readiness to realize an autosuggestion.

Suggestion. The subconscious realization of an idea. (See also **Ideoreflex Process.**)

Transference. The mental substitution, for an abstract emotional object, of some visible object which can symbolically represent it.

Unconscious. See **Subconscious.**

PREFACE.

This work owes its existence to observations of the effects of therapeutic suggestion upon individuals subject to contrary sexuality. The favorable results obtained in "congenital" urnings by psychical treatment in the hypnotic state placed before me the alternative either to assume that suggestion is capable of influencing congenital abnormalities of the mind or to prove that in the idea of homo-sexuality at present prevalent the hereditary factor is overestimated, to the disadvantage of educational influences. Thus it became necessary to examine more carefully the etiology and pathogenesis of the perverse tendencies of the sexual life. Onanism and functional (psychical or relative) impotence, as constant accompaniments of sexual perversions, likewise demanded more thorough study; and in this work, in separate sections, they are considered both pathologically and therapeutically, as far as is necessary for an understanding of paræsthesia sexualis.

But the phenomena of sexual anæsthesia and uranism in the female sex could be given but brief consideration,—first, because in medical practice and social life they have attained nothing like the importance of male homo-sexuality; and, secondly, because, owing to the infrequency of these anomalies, I have had no opportunity for personal observation of them.

Thus, the title of the book, strictly speaking, does not correspond exactly with its contents; for it emphasizes only the therapeutic aspect, and should really be: "*Pathological and Suggestive Therapeutic Studies of the Abnormal Manifestations of the Sexual Instinct.*" But the title used was chosen for the sake of brevity, and to indicate that the studies of the pathological side of the subject became essential only from a therapeutic stand-point; in other words, that, to a certain extent, they are the foundation for a correct comprehension of the therapeutics of the subject.

Among the most important tasks confronting neuro-

pathology, and one offering richest returns, is undoubtedly the establishment of precise indications for the employment of psychical therapeutics; to which Wilhelm Erb, with clearness of view, has lately called attention, both with reference to psychical treatment in the waking state, as well as to hypnotic suggestion.[1] Though, in spite of the obstinate opposition and continued indifference of prominent clinicians, all the greater series of experiments of late years agree in demonstrating that with necessary precautions hypnotic suggestion, used for remedial purposes, after the methods of "Liébeault, Bernheim, and Forel," is an effective and harmless therapeutic agent;[2] and though thus the question concerning the justification of hypnotic suggestion and its admission among the available means of our therapeutic armamentarium may at last be regarded as settled, yet the exact determination of the sphere of therapeutic operation of hypnotic suggestion may be regarded as the second important part of the problem to be solved. Experimentation in the most heterogeneous domains of disease—external and internal, organic and functional—has now to establish a place for systematic application of suggestion in functional disturbances of certain kinds, by the side of other remedial measures, with exact valuation and comparison.

[1] Wilhelm Erb, "Die nächsten Aufgaben der Nervenpathologie," Deutsche Zeitschrift für Nervenheilkunde, Vogel, Leipzig, 1891, p. 3.

[2] (*a*) Comp. Ringier: Erfolge des therapeutischen Hypnotismus in der Landpraxis (Lehmann, München, 1891). The author reviews 210 cases in his practice, which fulfill all requirements with reference to details of description, numerical grouping, continuance of observation after discharge, etc. He has never seen hypnosis have an injurious influence.

(*b*) Van Renterghem and von Eeden: Comte rendu des résultats obtenus pendant la première période bisannuelle, 1887–1889 (Brussels, Manceaux). The authors, whose clinic I visited in 1891, likewise testify to the innocuousness of therapeutic hypnosis, and were able to add nearly 1000 cases to the 414 cases of the article cited, which had since been studied.

(*c*) Wetterstrand, according to his work, "Der Hypnotismus und Seine Anwendung in der praktischen Medicin" (Urban und Schwarzenberg, Leipzig and Vienna), in the course of the last few years, has subjected 3200 persons to hypnotic procedures, and induced hypnosis some 60,000 times, without observing any injurious results.

(*d*) Von Corval ("Suggestivetherapie," Realencyclopädie der gesammten Heilkunde, von Eulenburg, Encyclopäd. Jahrbücher, Bd. i, Urban and Schwarzenberg) gives a complete review of this branch of therapeutics, and, from his own as well as from the experience of others in general, comes to the conclusion that hypnosis, correctly employed, is unaccompanied by any danger.

If, as Erb justly remarks, this limitation to certain fields dispels many illusions; still, the results of such investigations are incomparably more valuable to science than the generalization which looks upon suggestion as a "panacea." Thus it will be necessary next to arrange the suggestive-therapeutic material after the manner as yet used but by two observers, Van Renterghem and Ringier (compare foot-note), which is followed in this work.

The duration of the effects of suggestive treatment seems of great importance. Like Ringier, the author gave especial

(*e*) Minde, in his learned work, "Ueber Hypnotismus" (Diepolder, München, 1891), which is supplied with many important proofs taken from literature (p. 62), speaks of the "dangers" of inducing hypnosis. According to him, these result from light-minded play, thoughtless experimentation, and the desire to satisfy curiosity and vanity by public exhibitions for amusement, and they are usually to be ascribed to dilettantic awkwardness or incorrect methods, or to auto-suggestion in the subjects. Minde also thinks (p. 66) these dangers may all be avoided with proper care.

(*f*) Prof. von Krafft-Ebing expresses his views on this point in his last article on hypnotism ("Zur Verwerthung der Suggestionstherapie in Psychosen und Neurosen," Wiener klin. Wochenschrift, 1891, No. 43), in the following words: "Treatment by hypnotic suggestion, according to my experience, is innocuous when it is scientifically employed with due reference to the circumstances of the individual case."

(*g*) Preyer (Hypnotismus, "Vorlesungen," Urban and Schwarzenberg, Leipzig and Vienna, 1890, p. 146) also warmly commends the employment of hypnotic suggestion, and thinks that "it can have an injurious effect only when unskillfully used."

(*h*) Liébeault, who during thirty years has hypnotized 10,000 persons (some of them more than 100 times), ascribes his early "petits malheurs" to incorrect procedure; and with proper precaution he has never observed untoward effects to follow hypnosis. Comp. Revue de l'hypnot., i, p. 105 *et seq.*

(*i*) Professor Bernheim, from his observations on several thousand patients, has lately expressed himself as follows: "*Suggestion often cures; when it does not cure, it ameliorates; and if it does not benefit, it is still harmless.*" Comp. Hypnotisme, Suggestion, Psychotherapie, Doin, Paris, 1891, p. 18.

(*k*) Grossmann used hypnosis in 30 cases of influenza, and found the legend of its dangers unconfirmed; on the contrary, he characterizes suggestion as a powerful means of cure. Comp. Grossmann, Die Enfolge der Suggestionstherapie bei Influenza, Brieger, Berlin, 1892, p. 2.

(*l*) Professor Hirt (Breslau), from August, 1889, to the middle of April, 1890, made hypnotic experiments for therapeutic purposes on 598 persons. More than 4000 sittings have proved to him that hypnosis is never accompanied by *harmful effects*, even when frequently induced in the same individual. On the other hand, Hirt is greatly opposed to allowing the laity and unqualified persons to practice it; and he warns against premature and erroneous judgments of it, which are only too willingly credited by those unqualified to form an opinion. Comp. Wiener med. Wochenschrift, 1890, Nos. 27 and 30.

(*m*) The evidence mentioned is augmented by the wide experiences of Forel, Moll, and numerous other experimenters, all of which leads to the conclusion that, with proper individualization of hypnotism for therapeutic purposes, it is devoid of any disadvantages.

Observations of the author on more than 300 persons, of whom many were hypnotized more than 100 times and some 200 or 300 times, also speak in favor of the harmlessness of therapeutic suggestion.

attention to the duration of the suggestive-therapeutic results after cessation of treatment. Many of the patients were very soon beyond observation, and therefore, with the best of will, it was impossible to obtain late reports of all of them. Nevertheless, it has been possible for the author, as it has been for Prof. von Krafft-Ebing, to continue to observe many patients for several years after cessation of treatment. In one of the author's cases the time of observation after discharge was two years and seven months, and in several other cases about one year and eight months. Thus the tables here are made to indicate cases of "recovery with later reports," and cases of "recovery without later reports."

Where possible, for the sake of objectivity, I have allowed patients to speak for themselves, and give their letters *verbatim*. The custom, which is certainly justified, of believing in the reality of disease in many cases only when a pathologico-anatomical substratum is appreciable and demonstrable to our senses, even with but slight functional disturbance, has led many physicians to regard, in a one-sided manner, states of subjective disturbance without such substratum in many patients; and to distrust their testimony concerning subjective symptoms, as well as their statements concerning favorable changes in such symptoms. Self-deception in the patient, unconscious auto-suggestion on the part of the physician, exaggeration of the results on both sides, and many similar phrases are not infrequently heard instead of well-founded objections. In reply to this it may be stated: The reader may form his own judgment of the conscientiousness and objectivity of the descriptions, from the histories of the cases. On this point I fear that by pedantic communication of details which, perhaps, are interesting only in a negative way, I have made great demand upon the patience of my readers; but I hope that my effort to describe actual facts as exactly as possible will at least receive recognition. As for the second objection, an opponent using such an argument would also be driven to deny the existence of pain, for which we have no appreciable objective substratum. But what other evidences of pain are there than the statements and gestures of

the patient, which also hold for the majority of disturbances of the sensory sphere, for psychoses, etc.? And though a commendable attempt has lately been made to establish objective signs in certain cases of neurasthenia, still, in his work, Löwenfeld[1] designates neurasthenia as that affection for which the very absence of objective symptoms is characteristic. The untenableness of such objections as those mentioned is so evident that more extended discussion of them would be superfluous.

It may be questioned whether it is justifiable to discuss the anomalies of the sexual instinct apart, instead of treating of them in their proper place in psychiatry. As a rule, they are certainly only symptoms of a constitutional malady or of a weakened state of the brain, which present themselves in the various forms of sexual perversion.

Moreover, attention has been directed to the baneful influence possibly exerted by such publications as "Psychopathia Sexualis." To be sure, the appearance of seven editions of the book could not be accounted for, were its circulation confined to scientific circles. Therefore, it is not to be denied that a pornographic interest on the part of the public is accountable for a part of its wide circulation. But, in spite of this disadvantage, the injury done by implanting knowledge of sexual pathology in unqualified individuals is not to be compared with the good accomplished. History shows that uranism was very wide-spread long before the appearance of "Psychopathia Sexualis." The courts have constantly to deal with sexual crimes, in which the responsibility of the accused comes in question. For the physician himself, the sexual anomalies, treated as they are in text-books on psychiatry in a distant manner, are in greater part a *terra incognita*. Exact knowledge of the causes and conditions of development of sexual aberrations, and of the influence on them of hereditary constitution, education, the impressions of every-day life, and our modern, refined civilization, is the pre-requisite for a rational prophylaxis of sexual aberrations and a correct sexual education. Without careful study of the circumstances which attend the

[1] Löwenfeld: Die objectiven Zeichen der Neurasthenie, Lehmann, München, 1892.

development of sexual anomalies, we should never be in a position to use effectual therapeutic means. The majority of these unfortunate patients—von Krafft-Ebing calls them Nature's step-children—are devoid of insight into their malady; like insane patients destitute of understanding of the ethical development of man, they are happy in their abnormal instinctive tendency. For this reason, in spite of the great prevalence of uranism, very few of its subjects seek medical treatment. While the terminal forms of abnormal sexuality end in asylums for the insane, the doubtful cases, in which incompleteness of development or apparent viciousness renders correct diagnosis difficult, make up the majority. But a thorough knowledge of the aberrations of the sexual instinct is absolutely indispensable to the jurist. The reasons given are thus sufficiently important to prove the need for a hand-book on "psychopathia sexualis."

But a thorough treatment of the subject seems even more important in the light of the theory of suggestion. Thanks to therapeutic nihilism, which, unfortunately, still finds numerous adherents among physicians, until now such patients have remained the life-long victims of their imperative feelings, and not infrequently have finally seen themselves placed before the alternatives of the prison or the asylum; to say nothing of a consciousness, ever more acutely felt with advancing years, of a useless existence,—at least, as far as the foundation of a family is concerned.

By means of suggestion, especially by its application in the hypnotic state, the possibility—this much may be said with certainty from the seventy cases detailed in this work—is demonstrated to us that aberrations of instinctive life from its proper channel may be corrected.

The manifestations mentioned may be regarded as imperative sensations and imperative ideas, which occur either as pure auto-suggestion or have their origin in organic conditions. The ideational stimuli, induced in the brain by suggestion from another, are in a measure imperative ideas *in statu nascendi*, which —assisted by the law of the ideomotor and ideodynamic reflex transference, with individually suitable and correct wording,

and, in case of necessity, with cumulative application in repeated sittings—gradually gain irresistible power over the patients, and thus finally assume auto-suggestive direction of their conduct. According to this we are able to remove by suggestion abnormal moods, affects, feelings, instincts, ideas, and even hallucinations and illusions. The suggestive influence, however, reaches its limits in inherited constitution or predisposition of the brain, having its root in organic conditions; and likewise in "phenomena having a *very deep* foundation in the psychical mechanism" (von Krafft-Ebing).

The proof offered by me in this book, that a much larger proportion of sexual aberrations than has heretofore been presumed is, in pathogenesis, to be referred to external conditions (accidental causes, education), opens to psycho-therapeutics a much wider field in this class of cases, with points of departure essentially much more favorable. In spite of the great difficulties which frequently enough attend the treatment of such patients, it will become a hopeful and productive task for the therapeutics of the future.

For the stimulus to the study of this subject, I am especially indebted to the well-known work of Prof. von Krafft-Ebing, which has been constantly by my side as a guide in these questions; and if in some points the results of my studies do not accord with those of my highly-honored teacher, my indebtedness is thus increased, since in the cases of his book I found the way indicated which has been followed in this work.

The humane purpose of this work with reference to therapeutics, as well as the effort to arrive at an unprejudiced explanation and truth, should be sufficient to overcome any scruples to which the sexual character of the subject might give rise. This circumstance made it especially obligatory for the author to carefully avoid anything like a popular style of expression, and to preserve as carefully as possible, in spirit and letter, the scientific character of the work.

When one considers the difficulties which suggestive therapeutics has still to encounter in the larger part of the public, and how few psycho-sexual cases apply to the physician,—not to

speak of their asking for treatment, especially hypnotic treatment,—then a series of seventy cases, therapeutically considered, forms a basis, in a measure, sufficient for the formation of a judgment concerning the prospect of cure of such patients, especially when the long duration and care of observation in a number of cases is also taken into account.

Of the 70 therapeutic observations detailed in this work, 22 have already appeared in various publications, journals, books, etc., viz.: Cases 9, 31, 32, 39, 40, 41, 42, 43, 44, 45, 46, 47, 50, 53, 54, 55, 56, 57, 58, 59, 60, 61.

Twenty-four cases have been placed at my disposal, in manuscript, for use in this work, by recognized specialists in the field of suggestive therapeutics, viz.: Cases 1, 2, 3, 4, 5, 6, 7, 8, 17, 19, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 48, 49, 51, 52.

In addition, there are 24 cases of my own, of which but one has yet been published (in von Krafft-Ebing's "Psychopathia Sexualis,"), viz.: Cases 10, 11, 12, 13, 14, 15, 16, 18, 20, 33, 34, 35, 36, 37, 38, 62, 63, 64, 65, 66, 67, 68, 69, 70.

As a rule, the authors made use of the Bernheim-Liébeault methods of hypnosis, where nothing particular is stated on this point.

In order to estimate the depth of hypnosis, Liébeault has recommended its division into six degrees, Professor Bernheim into nine, and Professor Forel into three. The material of this work is arranged in accordance with the division into three degrees, and follows this *schema*:—

I. *Somnolence.*—The individual but slightly influenced, with the use of all his energy is still able to resist the suggestion and open his eyes. Consciousness intact.

II. *Hypotaxis.*—The individual is no longer able to resist suggestions. No amnesia.

III. *Somnambulism.*[1]—With the manifestations of the

[1] In order to give an idea of the susceptibility to hypnosis in general, I give here the numerical results of several authors for comparison with my own, under the foregoing classification. My results, up to November, 1890, among the people of Munich, were as follow:—

second degree there is also amnesia, or susceptibility to hallucination, or both.

Post-hypnotic phenomena occur with somnambulism, and even with the second degree.

Finally, it is my pleasant duty to acknowledge in this place my indebtedness to all those who, by their co-operation in any way, have assisted in the production of this book; especially to my honored guide and teacher in the domain of suggestive therapeutics, Dr. Forel, Professor of Psychiatry in Zürich, to whom the work is dedicated; and, further, to Dr. R. von Krafft-Ebing, Professor of Psychiatry and Neurology in Vienna, for his repeated encouragement and advice.

Besides those named, I have been assisted in the preparation of this work—by means of patients kindly sent to me, by unpublished histories of cases placed at my disposal, and by literary communications and advice—by the following gentle-

	Persons.		Per Cent.
Refractory,	29	=	12.08
Somnolence,	42	=	17.5
Hypotaxis,	100	=	41.67
Somnambulism,	69	=	28.75
	240		100.00

The results at Nancy (Liébeault), Amsterdam (Van Renterghem), and in Switzerland (Ringier), in comparison, are as follow:—

	Liébeault, 1011 Persons.	Liébeault, 753 Persons.	Van Renterghem, 178 Persons.	Ringier, 221 Persons.	Schrenck-Notzing, 240 Persons.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Refractory	2.67	7.97	3.93	5.43	12.08
Somnolence	3.26	10.09	5.06	7.24	17.50
Hypotaxis	78.04	63.21	79.77	52.49	41.67
Somnambulism	16.02	18.73	11.24	34.84	28.75
	99.99	100.00	100.00	100.00	100.00

According to my preliminary summary, the susceptibility to hypnosis of 8705 persons, of various nationalities, is shown by the following figures:—

	Persons.		Per Cent.
Refractory,	519	=	6
Somnolence,	2557	=	29
Hypotaxis,	4316	=	49
Somnambulism,	1313	=	15
	8705		100

Advanced years, on the whole, diminish susceptibility, while the figures for earliest youth do not quite reach those for middle life.

men: Dr. Bernheim, Professor of Internal Medicine at Nancy; Dr. Stumpf, Professor of Philosophy (Munich); Dr. Gussman (Stuttgart); the *privat-docenten*, Dr. Kopp (Munich) and Dr. Max Dessoir (Berlin); Dr. Liébeault (Nancy); Dr. Wetterstrand (Stockholm); Dr. Van Renterghem (Amsterdam); Dr. Rosenberg (Carlsruhe); Dr. von Hösslin (Neuwittelsbach, near Munich); Max Offner (Munich); and Mr. X. X., urning.

I here express my thanks to them all for their friendly and helpful co-operation.

THE AUTHOR.

MUNICH, October, 1894.

TRANSLATOR'S PREFACE.

THE favorable reception given von Krafft-Ebing's "Psychopathia Sexualis" induced me to undertake an English version of the work by von Schrenck-Notzing. The views for which the latter contends so ably are in striking contrast with those held by von Krafft-Ebing, and, for that reason, this work deserves to be placed in English by the side of "Psychopathia Sexualis." The importance of the question treated in these works cannot be overestimated; for upon the decision concerning the influence of congenital and educational factors must rest the theory and art of human culture. In the study of these perversions a wide field is opened to view, disclosing possibilities which therapeutic nihilism looked upon as dreams.

As a contribution to the literature of suggestive therapeutics this work stands without a rival, in view of the duration of the observation of reported cures.

A growing experience in cases of sexual perversion but tends to confirm me in von Schrenck-Notzing's views, and I hope soon to make an original contribution to the literature of this subject.

The medico-legal question of responsibility in sexual perversions is one of great importance, and, as here clearly shown, is to be decided not by the fact of perversion, but by the psychical condition as a whole.

CHARLES GILBERT CHADDOCK, M.D.

ST. LOUIS, MO.,
December, 1894.

I. SEXUAL HYPERÆSTHESIA.

CHAPTER I.

PATHOLOGY.

The great importance of premature excitation of sexual feelings, with the masturbation usually accompanying it, in the production of psycho-sexual abnormalities, justifies an examination here of its causes and their nature. In his classification of the cerebrally conditioned sexual neuroses, von Krafft-Ebing correctly differentiates sexual instinct arising in childhood and sexual desire re-awakened in old age (paradoxia) from abnormal intensification of it (hyperæsthesia[1]). In a study of onanism from a therapeutic stand-point, based upon histories of patients, it is difficult to carry out this principle. According to von Krafft-Ebing, we have to do with actual paradoxia in a child only when sexual feelings and impulses occur as a result of *cerebral processes*, but not, by any means, in the numerous cases where peripheral causes (phimosis, balanitis, oxyuris, etc.) induce manipulation of the genitals. This etiological distinction cannot always be made in cases of onanism; and it cannot be denied that an original peripheral stimulus is capable of inducing the same symptoms of psycho-sexual abnormality as those resulting from a purely central cause, and, in a measure, may become the exciting cause of the premature appearance of sexual desire. On the contrary, in almost all cases an abnormally intense sexual desire is the result of masturbation in childhood; a desire which is scarcely ever satiated within the limits of that indulgence which is usually sufficient with relatively frequent repetition of intercourse.

The individual, at first suffering with "paradoxia," is soon affected with "hyperæsthesia of the sexual instinct." But, also

[1] Comp. von Krafft-Ebing, "Psychopathia Sexualis," Chaddock's translation (F. A. Davis Co., Phila., 1892), pp. 48, 51–55.

in so far as *onanism* in itself presumes an unconquerable impulse, and incapability to control it, it may be classified as hyperæsthesia sexualis.

In spite of full recognition of the theoretical and clinical importance of von Krafft-Ebing's classification, practical considerations in the main have induced me to unite the cases at my command under the title of "Sexual Hyperæsthesia," and, for the sake of clearness, to divide them into two classes:—

1. Onanism (auto-sexual indulgence).

2. Satyriasis and nymphomania (hetero-sexual indulgence).

Upon the opinions we entertain of the nature of these pathological conditions depend the therapeutic measures. Only an exact study of the various forms of manifestation in which *hyperæsthesia sexualis* may appear, as well as a correct appreciation of other methods of treatment, can make clear the indications for the application of therapeutic suggestion.

A. Onanism.

The most common method of abnormal satisfaction of sexual desire is onanism (derived from the word Onan; comp. Genesis, xxxvi, 9). By this term, in its widest sense, are understood all means used by either sex to induce the sexual orgasm outside of the conditions of normal sexual intercourse.[1]

According to this definition, even those acts which in nowise resemble coitus, but which are practiced by one person on another for the artificial induction of the sexual orgasm, are to be regarded as onanistic, no matter whether the persons be of the same or of opposite sex. Therefore, coitus in os, coitus inter mammæ, mutual masturbation, etc., may be designated as onanistic acts performed by means of the body of another person.

These perverse manifestations,—*i.e.*, those wanting the purpose of procreation,—when practiced inordinately or homosexually, are, as a rule, to be regarded as symptoms of forms of psycho-sexual disease which we shall consider in later chapters.

[1] Comp. Christian (Charenton), Extr. du Hist. encyclop. des scienc. médic.; and Centralb. für Nervenheilk., von Erlenmeyer, 1882.

In a narrower sense, we understand by onanism those acts which an individual carries out on himself in order to induce the sexual orgasm. Only this manner of sexual indulgence, which is the most common, will occupy us here.

Causes and Predisposition.—The occasion for handling the genitals frequently arises in connection with irritation of them in childhood (eczema, pruritus, phimosis with consequent accumulation of smegma). Besides this source of masturbation, which is, to a certain extent, involuntary, there are movements, made for other purposes, which may accidentally lead to masturbation,—for example, gymnastics, running sewing-machines,[1] etc., while wearing too close-fitting clothing. In such cases, therefore, the participation of the fancy in the lustful feeling is secondary and concomitant. In fact, excessive auto-masturbation may exist for years with perfect purity of the child's imagination; indeed, with complete ignorance of the sexual relations. In one of the cases treated by me onanism had been practiced for eight years, and the patient had never had any impure fancy in connection with it; she could not have had, owing to her absolute ignorance of the sexual relations. It seems to me that, in the numerous publications on this subject, the significance of this point has not received due consideration. And yet the associations which become connected with the onanistic act are of fundamental importance in the etiology and development of the special form of the resulting psycho-sexual abnormality.

More frequently than the accidental influences affecting the genitals that have been mentioned, seduction, bad example, etc., occasion the development of the vice, especially in schools, in boys' and girls' academies, and in prisons and houses of correction. Almost an invariable accompaniment of masturbation thus acquired is the implication of the imagination through pictures having a sexual and obscene content. Often, too, in the family itself the cause lies in nurses, servant-maids, and servants who, either for their own pleasure or to quiet the

[1] Comp. Fournier, De l'onanisme. 4th ed. Paris, 1885, p. 67.

crying children, manipulate their genitals.[1] It is also clear that certain subjects taught turn the attention of pupils to sexual matters, and thus give childish fancy an evil direction. It is only necessary to recall certain passages in Greek and Roman classics, and certain chapters in the Bible that are not to be misunderstood.

Gyurkovechky[2] is of the opinion that idleness of pupils during play-hours, spicy food, and exciting drinks, as well as early retiring and late rising, are to be regarded as predisposing causes of inordinate onanism. Even though it cannot be denied that any of these circumstances may give an onanist welcome opportunity to indulge excessively in his vice, it is difficult to understand how such influences could lead a pure child to masturbation. Indeed, in all cases it requires some other extraneous influence to lead the child to the first indulgence in the pernicious habit.

Too, even in individuals untainted hereditarily, continued onanistic irritation of the central nervous system is capable of inducing a neuropathic constitution, and, in consequence, numerous maladies. Moreover, continued or temporary abstinence from sexual intercourse, after the occurrence of sexual maturity, predisposes to the development of neurasthenia and sexual hyperexcitability, at least in many untainted individuals, who then resort to auto-masturbation *faute de mieux*. In the majority of cases which come for medical treatment, however, the individuals are of tainted heredity.

Lombroso[3] examined 11 onanists, and found: without physical anomalies, 3; with physical anomalies, 8; parents normal, 3; unknown, 1; abnormal, 7.

In cases of neuropathic predisposition onanism frequently becomes the exciting cause of the malady, while, according to von Krafft-Ebing's[4] experience, which is no less extensive, in untainted individuals the limits of an asthenic neuropsychosis

are scarcely ever passed as a result of onanistic excesses. To be sure, the addition of some other exciting cause may, on the basis of the acquired neuropathic condition, give rise to any form of insanity. But there are also cases in which onanism is to be regarded as an immediate symptom of the neuropathic state or psychosis; for example, in maniacal states with sexual excitement, as they occur in hysteria and epilepsy, and as the forerunners of mania and paretic dementia.[1] In his classification based upon anatomical principles, Magnan classifies a certain form of onanism as belonging to the "spinal" sexual anomalies, and speaks of automatism of the genital reflex centre. He mentions a female idiot, aged 7, who masturbated continuously after her third year, and who could not be kept from it by any means. Magnan believes that the girl masturbated as a result of irritation seated in the genito-spinal centre; for all sensorial cerebral functions were to be regarded as absent.[2] Here it may be advantageous to review the anomalies of the sexual instinct in imbeciles and idiots. In relation to the symptoms of paradoxical expression of the sexual appetite,—sexual hyperæsthesia in general,—according to the statements of Sollier[3] and Bourneville,[4] onanism is of the greatest importance. The author first named expresses himself as follows:—

"In uncleanly and incurable idiots there can be no thought of a real sexual instinct; the onanism which most of them practice cannot be regarded as its expression. In idiots capable of education sexual instinct may make itself noticeable, but it is always weak. Sometimes it is abnormally developed and perverse, but never normal. On the other hand, imbeciles are often prematurely developed, and, at the same time, they manifest most of the sexual perversions."

The most frequent and earliest aberration of the sexual instinct is, according to Sollier, onanism. Some masturbate

[4] Bourneville and Sollier, "Des anomalies des organs génitaux chez les idiots et les epileptiques," Progrès Médical, 1887.

automatically; others know what they do, and seek in the practice sexual gratification. Idiots of two or three years, who masturbate constantly, so to speak, belong to the first category. "With them it is a *tic* similar to others they present. That sexual desire has nothing to do with it is clear. Often there are seen malformations that are in nowise related to the sexual instinct. On the other hand, I have previously called attention to the fact that certain idiots experience pleasant sensations with their *tics*."

Automatic masturbation occurs at a certain age in idiotic dements. It is also found in very young idiots and imbeciles, as sometimes in normal children. In the latter the habit is abandoned with increasing years, especially with the occurrence of puberty and as a result of education. Even though idiotic children find a certain sexual satisfaction in the practice, it is not to be regarded as true sexual pleasure. Usually real sexual pleasure is to be observed only after the genitals have reached their full development at puberty. In many instances, however, true sexual instinct is developed remarkably early. Sollier saw several idiots of very low intelligence, who, from the fourth or fifth year, found pleasure in touching little girls or women. Many sought to violate their little sisters and touch them indecently; others approached their mothers by lifting their skirts. "Often in asylums for idiots they are seen to attempt indecent fondling of their nurses, and they like to come in contact with them, thus being thrown into a state of general excitement. These inclinations are observed toward women and girls more frequently than toward children of the same sex. This seems to demonstrate that the inclination is a true sexual instinct. But in normal children sexual excitation occurs more frequently, and that before puberty, than is suspected."

In imbeciles onanism is less frequent up to puberty than in idiots; but after that period the relation is reversed. After puberty onanism occurs under the influence of the sexual instinct for sexual gratification. In this respect the girl is like the boy. Sollier reports: "A girl in Bicêtre masturbated by

rubbing the thighs together (the most common method), and thus finally induced an erythema of both thighs. In spite of this condition she continued the practice so long that the skin became gangrenous, and the surface of the sores could never be entirely healed."

According to the later psychiatric investigations (Christian, Kraepelin, Forel, Vogel, Löwenfeld, Uffelmann, von Krafft-Ebing, etc.[1]) it is put beyond doubt that habitual masturbation is either a concomitant symptom of an existent neuropathic condition, or, as a rule, induces, in connection with inherited or acquired predisposition, pronounced disturbances of the nervous system.

Forms of Onanism.—The induction of sexual orgasm in onanists is either by means of *peripheral* or *central* irritation, or *both simultaneously.* From a practical stand-point, three groups may be distinguished: 1. Onanism by means of tactile excitation. 2. Onanism by means of psychical excitation. 3. Onanism by means of a combination of sensory and ideational excitation.

1. *Onanism by Means of Tactile Excitation* (*Masturbation, Manustupration*).—While in the first group the implication of the imagination takes place as a secondary accompaniment, in the second group it is the principal means of gratification. Merely friction of the glans, rubbing of the clitoris, or other tactile irritation of erogenous areas (in women: vagina, cervix uteri, nipples, and, under pathological conditions, places in the proximity of the genitals and mammæ; in men: the skin of the external genitals, and, according to some authors, under pathological conditions, the anus), according to Hammond's[2] opinion, is not sufficient to induce the necessary degree of sensual excitation; rather, the peripheral stimulus induces ideas

[2] Hammond, Sexual Impotence.

with which pleasurable feelings become associated. The content of these ideas is, in the majority of instances, concerned with sexual relations and situations. The most common method of tactile stimulation of the genitals consists of rubbing, pressing, swinging movements of the thighs, or of fondling and friction with the hands. Females[1] make use of the most various objects for masturbation;[2] they insert large and small objects into the vagina, such as hairpins, crochet-hooks, needle-cases, lead-pencils, radishes, spools, and candles. "Married women," according to Winckel,[3] "choose fir-twigs, artificial penes made of bacon, and even pomade-jars and drinking-glasses. The most ludicrous combination of this kind that has ever been discovered was found by K. Schröder,—a pomade-jar and a cricket in the vagina." These objects, which easily slip from the hand, often give occasion for operative interference. One of my patients rubbed the clitoris with a sponge. Too, the ideas which accompany the manipulations sometimes concern strange objects. Thus, one of my patients who masturbated thirty years, and lived for the most part in the country, conceived that she was in coitus with a stallion.

Here but brief allusion can be made to the anthropological significance[4] of masturbation. Among the Khoikhoin (Nama Hottentots), according to Ploss,[5] in the youths of the female sex masturbation is so frequent that the practice might be regarded as a custom. Therefore, no especial secret is made of the matter, and in their tales and folk-lore the people speak of it as of a customary matter (Fritsch[6]).

The vice, even at the time of the arrival of the Spaniards, was wide-spread among the females of the Philippines; they had invented an artificial penis with which to gratify their insatiable

[3] Comp. Winckel, Diseases of Women.

[4] According to Mantegazza (Hygiene der Liebe, p. 83), the English physician, Copeland, has stated: "The Jews owe their great power of resisting many epidemic diseases and a certain mental deliberation to the fact that masturbation is unknown among them." That this statement is erroneous is shown by the experience of Mantegazza and others.

[5] Ploss, Das Weib, Leipzig, 1891, Bd. I, p. 330.

[6] Fritsch, Die Eingeboren Südafrikas, Breslau, 1873, pp. 111, 280.

desires, and they had other similar means for the satisfaction of their unnatural lust (Blumentritt[1]).

Manipulations which cause enlargement of the clitoris and labia minora, it seems, are indulged in either purposelessly (at least, not in conscious action) or for various purposes. According to Ploss,[2] among many barbarous peoples the indulgence of the youthful females in masturbation, pleasurable titillation, and lustful pinching and pulling of the excitable portions of the genitals, is the cause of their gradual change of form. Still, perhaps these practices are undertaken with the more or less clearly-conscious purpose, not only of increasing the individual's own lustful pleasure, but also with a view to so change the genitals as to better adapt them for the performance of tribadism,—a vice which has always been very wide-spread in the Orient.

2. *Onanism by Means of Psychical Stimuli* (*Psychical Onanism*).—Central excitation of the sexual orgasm, as by simple memory-pictures, is always a sign of psycho-sexual hyperæsthesia, and is to be regarded as occurring, for the most part, as a manifestation of cases falling in group 1; for example, in hysterical individuals, those tainted hereditarily, and in states of psychical exaltation. According to von Krafft-Ebing,[3] where this means is effectual the fancy is abnormally excitable, and associations are facilitated.

The pollutions which take place in both sexes as a result of erotic thoughts, both in dreams and the waking state, must be placed in this class; the sensual excitation is brought about purely by an act of the imagination. Thus, for example, a man concentrates his entire attention in thought upon a female; "fancies that he approaches her vulva and attempts immissio penis; then he thinks of the various stages of coitus, until finally he experiences the complete orgasm."[4]

According to Hammond, there are men who know only

[3] Von Krafft-Ebing, Psychopathia Sexualis, p. 39.

[4] Hammond, Sexual Impotence.

this kind of excitation, and who have no erection in the normal way. As a rule, this hyperæsthesia occurs after masturbatic or other sexual excesses; so that the matter is one of memory-pictures in different variations. One of my patients is also able to indulge in the pleasure of this ideal coitus at any time. A quiet, comfortable position, either lying or sitting, is the preparatory measure necessary for success. Then he allows his fancy free rein, and dreams intensely—though consciousness is intact—that he is in the desired situation, until ejaculation takes place. This calls to mind the artificial induction of dreams by narcotics. In "The Significance of Narcotics in Hypnotism"[1] I have shown that narcotics (alcohol, opium, etc.), especially Indian hemp, induce a condition favorable for the acceptance of suggestions,—even for *auto-suggestions;* hence the use of haschish by Orientals when they wish to give themselves up entirely to a drunken imagination in which ideas of a sexual character play the principal *rôle.*

Too, such pollutions in the female sex, which are most frequently induced in sleep by erotic dreams, are not without importance. At the height of sexual excitement an abundant secretion is emptied from the glands of Bartholini. In many women, as Robinson[2] states, a lustful, convulsive sensation, which is also painful, occurs, which Robinson attributes to contraction of the constrictor cunni. In his opinion, previous masturbation and regular coitus are to be regarded as the etiological factors. Many of these patients experience a subsequent feeling of relief, and the next morning are refreshed; many others awake with pain in the back after pollution.

The induction of orgasm by erotic ideas is of especial interest by reason of the religious significance that has been given it in the imagination of ignorant peoples. "There is an uncommonly wide-spread belief that evil spirits of a certain kind possess the power to visit young maidens and wives, and also youths and husbands, while in bed at night, of course always in

[1] Schriften der Gesellschafft für Psychologische Forschung (Leipzig, Abel, 1891), Heft 1.

[2] Robinson, "Klin. Beob. über Pollutionen beim Weibl. Geschlecht," Med. Ag., 1889, No. 7.

the seductive form of the opposite sex, in order to perform coitus with them.[1] The feeling of depression on the day following the pollutions is ascribed to the power of the evil spirit of the night to sap the strength. These demons, which during the middle ages were known as incubus and succubus, as *ephialtes* and *hyphialtes*, as night-power or weight, as night-mare, etc., were known to the civilized peoples of Western Asia many centuries before the beginning of our historical reckoning, and they were feared under the names of night-men and night-women." According to Ploss, in the ruins of Ninevah were found a great number of tablets of terra-cotta from the library of Assurbanipalus (Sardanapalus of the Bible) on which there were cuneiform inscriptions. Among them were formulæ for exorcism and prayers in Accadian characters, with an Assyrian translation inscribed above them, which were directed against the night-men (lillal) and the night-women (kiel-lillal). We are justified in assuming that there was a belief in the possibility of cohabitation with a god, where we find that mature maidens who were approaching marriage sacrificed their maidenhood in the temple as a custom. Legendary demoniacal animals are also frequently held to be the progenitors of whole tribes, especially among the Indians and Polynesians. The consorting with the devil for years, which comes to us from the fourteenth and fifteenth centuries, is well known. Usually this sexual congress took place at night; but women were even "found in broad daylight in the fields entirely naked, and sometimes their husbands found them in the embrace of the devil," etc.

The forest has always been regarded as the place of preference for the attacks of demons upon women. The lust of satyrs, fauns, and sylvans is well known; and the Druids of the ancient Gauls and the forest-god of the Germans may be recalled.

In the islands of Aaro the unchaste forest-god has power only over menstruating women, who, therefore, dare not enter a forest. The states of excitement in the genital apparatus at the time of puberty in both sexes, and at the time of menstruation

[1] Ploss, Das Weib, Leipzig, 1891, Bd. i, p. 332.

in maidens and women, have a reflex effect upon the central nervous system, and induce erotic ideas that may attain the intensity of hallucinations, which then correspond with the religious belief of the individuals. The centrifugal effect of such ideas is to induce, either in the sleeping or waking state, should they be intense enough, the well-known lustful feelings; and this differs from voluntary psychical onanism only in the unconscious and latent excitation of the imagination. Essentially, however, in both cases it is ideal cohabitation,—the induction of orgasm by sexual ideas which on their part are conditioned by organic or psychical causes, and which, therefore, are physical in any case.

3. *Onanism by Means of a Combination of Sensory and Ideational Excitation.*—In onanists of the third group the imagination alone is inadequate for the induction of sexual orgasm. On the contrary, the imagination must be intensely excited by a sensory impression in order to induce a sufficient degree of sensual excitement in the nervous system. Often sensory impressions that appear to have no relation to the sexual life (optical and tactile impressions, odors, and tastes) are sufficient to excite the psycho-sexual mechanism. That, as von Krafft-Ebing[1] thinks, in all cases lascivious ideas are induced, according to my experience, seems questionable. With hyperexcitation of the genital centres, ejaculation occurs without other tactile irritation of the sexual organs, as in psychical onanists. In other cases ideas alone are not sufficient to induce the orgasm, which takes place only with mechanical assistance (masturbation, pressing and rubbing of the thighs).

Too, in some individuals a variation is to be noticed, in that with extraordinary excitation the imagination is sufficient to conclude the act, while in other cases manipulations complete the work. Thus, one of my patients reports that when he was 18 he excited himself sexually by looking at obscene photographs; on one occasion only did the excitement become so intense as to cause spontaneous ejaculation, and then it was with a feeling of lustful pleasure such as he had never before experi-

[1] Von Krafft-Ebing, Psychopathia Sexualis.

enced. Another patient, who is at the same time of contrary sexuality, has erection only when he sees naked male nates. The idea of the nates is not sufficient, at least, in the waking state, though it is efficient in dreams. Two female onanists, seen in my practice, without any friction induced sexual orgasm by sensory impressions which had no sexual relation whatever. One practiced onanism in this way while hearing music, or while regarding landscape paintings, and that without anything like a lascivious idea. The other was sensually excited at the sight of the grandeurs of nature, such as the sea. Both patients indulged in onanism in the street, in cafés, in the theatre, and in street-cars, without in any way attracting the notice of those about them. While with the first there was no knowledge of sexual intercourse, with the second occurred ideas of a sexual nature. When she became attracted by the sight of an especially strong and handsome male form, orgasm would occur in one minute at most. The touch of the physician in the first examination induced it. Another patient is able to have ideal cohabitation at a distance. For example, he seats himself in the theatre *vis à vis* a lady attractive to him; then he allows his fancy free rein, and thus enjoys the pleasures of love by picturing so intensely to himself all the positions of coitus with the person that ejaculation results.

According to Hammond,[1] it seems that in America such persons form a kind of a union or society, and have certain signs by which they recognize one another. They call themselves by a common name, which signifies "a man who indulges in ideal coitus." They say that they can tell by a man's face whether he belongs to their society or not.

One of my patients, of contrary sexuality, had an ejaculation when the man who was the object of his love, and who had no suspicion of the condition of his friend, felt his pulse on an occasion of illness.

In another case of contrary sexuality the man experienced orgasm on merely shaking hands with a man especially attractive to him.

[1] Comp. Hammond, *loc. cit.*

Hammond's[1] observation in the case of an epileptic is also remarkable: "He took employment with a dealer in vegetables whom he liked to visit, in order to see beautiful women. When he had chosen his partner, he would concentrate his thoughts on her and imagine her in the most various exciting positions. It was not difficult, he said, to fancy her before his eyes entirely nude. Then he would make voluntary contractions of the glutei, the accelerator urinæ, and other muscles, and usually after no longer than a minute orgasm would occur. He could also induce sexual excitement when he thought of a lady he had just seen, without having her before his eyes. Natural sexual intercourse, on the other hand, afforded him no pleasure; on the contrary, he was absolutely impotent with women, and not even with the help of fancy was he able to have sensual pleasure in coitus. Finally he became absolutely unable to prevent the excitement which came on, and that without erection, merely at the sight of an attractive woman. Likewise a painting or wood-cut of a woman, dressed, nude, or half-nude, induced orgasm, with or without erection and ejaculation."

In the cases mentioned, optical, auditory, and tactile perceptions (examples of olfactory and gustatory impressions acting in this way are not known to me) are the causal factors in the excitation of the sexual sense, and, indeed, regularly with deviation from physiological conditions, and often without any relation in content to sexual matters. Many authors presume a more intimate relation between the olfactory and sensory senses (von Krafft-Ebing,[2] Althaus,[3] Cloquet[4]).

In his latest work, Moll[5] opposes this. In his opinion the relationship between olfactory impressions and the sexual instinct is not more intimate than that of many other sensory impressions, and that of sight with the sexual sense is much closer than that of smell; especially since it is questionable whether there is a special centre for sexual sensations.

[5] Moll, Die conträre Sexualempfindung, Berlin, 1891, pp. 183, 184.

The sensory impressions mentioned induce in the cerebral cortex sexual ideas, feelings, and impulses which, in hyperæsthetic individuals, may give rise to complete sexual satisfaction. When it is present in sufficient intensity, a memory-picture alone may have the same effect. While in this chapter, to a certain extent, only the exterior of unphysiological excitation and abnormal intensity of the sexual instinct interest us, in Section III we shall learn the great importance which is to be attributed to the content of the ideas which accompany the sexual excitement in giving perverse direction to the vita sexualis.

Dangers and Results of Onanism, with Especial Reference to Insanity.—Though onanism, where it is not a symptom of a psychopathic or neuropathic predisposition, may always be regarded from a moral stand-point as a vice, still the physician, as a rule, will be concerned only with such cases of it as present more or less profound disturbance of the nervous system. From a more humane point of view, this "error," this "sin of youth," is to be looked upon as a malady, as a disease presenting characteristic symptoms. Concerning the real cause of this injurious practice authors differ. Thus, Erb[1] regards the single onanistic act as no more harmful than that of normal coitus. He says: "The effect upon the nervous system in a man must be essentially the same, whether the friction of the glans takes place in the vagina or is otherwise carried out; the nervous shock in ejaculation remains the same; it might well be presumed that the nervous excitement would be greater where the female is used."

But in reply to this it may be stated that masturbatic acts, with the exception of such infrequent cases as those of Magnan,[2] which must be regarded as instances of psychoses, have a much more intense psychical effect than does coitus. The content of the ideas in every single onanistic act must overcome reality, and thus a much more intense strain of the imagination is necessary. And the imagination itself, even with infrequent practice of onanism, with respect to the accompanying psycho-

[1] Erb, Handbuch der Rückenmarkskrankheiten, p. 163.
[2] Comp. p. 5.

sexual product,—the content of ideas,—becomes artificially accustomed to a single direction of activity. We shall learn in Chapter IX the deleterious influence of the content of the ideas of masturbators in cases of severe psycho-sexual disease. Besides, the fact of self-indulgence, save with infrequent performance of the act, brings onanists into a peculiar and, I might say, unphysiological relation to the opposite sex. In that it destroys the sexual relation with the opposite sex, it weakens sexual desire and attacks the most powerful natural instinct—love's impulse—at its very root; it injures the whole sexual foundation, the basis of all ideal activities; it extinguishes the fire of sensual feeling, the most powerful incentive to the putting forth of strength, in both individual and social existence, in the world of beauty and morality.[1] Masturbation moderately practiced exercises, on a good constitution, no direct destroying effect, but it changes, when it is long indulged in, the character, the imagination, and the whole mental existence in a way that is unmistakable and, so to speak, necessary. These evil effects of onanism seem to us to be greater than those lesser disturbances which seldom affect materially the general health, and which Dr. Löwenfeld[2] describes in detail.

Still, in purely a physical sense, it seems questionable whether coitus and masturbation are equivalent acts. Gyurkovechky[3] found a history of greater depression and weariness after occasional indulgence in onanism than after considerable excessive coitus. According to the expression of many patients, the act of indulgence which leaves behind it the most intense feeling of well-being is that in which the semen is expelled with the greatest energy and strength. Any delay in the expulsion, anything like weakness or lack of energy in the completion of the act, has an incomparably weakening effect upon the nervous system. But Hammond[4] assumes that the sexual act, in that it requires a greater expenditure of muscular power, must certainly be more injurious than onanism with like frequency of indulg-

[1] Comp. von Krafft-Ebing, Psychopathia Sexualis, p. 5.

[4] Hammond, *loc. cit.*

ence; at least, with reference to ejaculation and orgasm. "For, with the orgasm and the loss of semen, it is a matter of indifference where the semen is deposited, whether in the vagina or in any other receptacle." This conflict in the opinions of the authors is easily overcome when we properly consider the accompanying effect of the psychical factor, which varies with the individuals, but which is constantly in play. Experience shows that masturbation, since opportunity for it is constantly present, is much more frequently practiced than natural sexual indulgence. The exhaustion of strength induced by frequent indulgence points to the frequent and severe material injury of the nervous system. When, by reason of defective or incomplete erection, an individual is incapable of coitus, masturbatic friction of the glans may still be performed with a flaccid member. The majority of cases of impotence (on this point all authors agree) depend upon excessive and early indulgence in onanism.

Hammond states that he observed complete impotence in married men who had practiced masturbation moderately without noteworthy injury to their general health. There are many young men, strange to say, who see nothing in self-abuse that is immoral, or who, at least, in case they understand the evil, are unable to resist it. Naturally, after marriage they find that legitimate intercourse only imperfectly satisfies their sexual instinct, and that it excites their sensual feeling much less than did the evil habit in which they previously indulged (Hammond).[1] The dreams which accompany the onanistic act are not realized in marriage, and to the great surprise of such patients their virility is well-nigh extinguished.

At the same time, between the sexual instinct longing for satisfaction and the effort to remain pure, there arises a terrible struggle, which, unfortunately, only too often ends in victory for the vice.[2] From this arises the moral depression of those who abstain. This and the ever-renewed struggle, as well as the onanistic stimulation, gradually undermine the nervous system.[3]

[1] Hammond, *loc. cit.*

[2] Comp. Leopold Caspar, Impotentia et Sterilitas Viriles, München, 1890, p. 77.

[3] Comp. Beard, Sexual Neurasthenia; and von Krafft-Ebing, "Neurosen und Psychosen durch sexuelle Abstinenz," Jahrb. für Psychiatrie, Bd. viii, pp. 1, 2.

In the course of time weakness of the whole nervous system occurs.[1] At the same time it is important whether the pernicious habit has been practiced from early youth or only from after about the twentieth year. The earlier the vice is indulged in, the more serious are its effects. In the functional injury to the central nervous system, the loss of semen is not of any essential pathogenetic significance. "While in coitus the act is quasi-reflex and automatic, onanism is voluntary, and must be attended by activity and expenditure of nervous material which possesses a higher functional value" (von Krafft-Ebing[2]). Meyer[3] thinks that the impulse to masturbate is stronger and more obstinate when the result of psychical predisposition, weaker when it is accidentally provoked. In the first instance, therefore, it has a more injurious effect upon the mental condition.

With reference to the deleterious effect of onanism on children, alienists and those versed in the hygiene of childhood agree that masturbation, besides inducing motor, sensory, and circulatory disturbances, etc., may give rise to lack of feeling; want of desire for child-like play, in as far as this does not give opportunity for the vice; a shy, retiring disposition; psychical irritability; inclination to paroxysms of anger and rage; and weakness of memory and judgment.

"When it is remembered that abnormal precocity of sexual desire is one of the peculiarities of a neuropathic constitution, the conclusion seems justified that the children whose insanity arises from onanism have been under the influence of

[1] Only orthodox one-sidedness of view and complete ignorance of physiological conditions of life make such a statement as the following explicable: "Not even the shadow of a proof has been cast to show that a nervous man is made nervous or insane by a moral life,—*i.e.*, complete abstinence from sexual intercourse." (Comp. A. Römer, M.D., Die Sittenreinheit vor dem Richterstuhl einer ärztlichen Autorität, Streitfragen, wissenschaftliches Fachorgan der deutschen Sittlichkeitsvereine, Berlin, 1892.) The pamphlet is opposed to the works of Moll and von Krafft-Ebing, and states that sexual errors arise either from "seduction" or from "personal evil" (*sic!*). But those who show a tendency to yield to "the evil inclinations of the human heart" (p. 12) should, according to the receipt of Dr. Römer, call to mind "the grand words of the Apostle Paul in the Epistles to the Romans (i, 26, 27, 32), as well as in those to the Galatians (v, 16 and 24)."

[2] Von Krafft-Ebing, Ueber Irreseln durch onanie bei Männern, *v. supra.*

[3] Ludwig Meyer, Die Beziehungen der krankh. Zustände und Vorgänge in den Sexualerg. des Weibes zu den Geistesstorungen, Berlin, 1869, p. 15 *et seq.*

that evil *ab ovo*" (Vogel,[1] Uffelmann[2]). In young children masturbation causes convulsions, choreic conditions, and mental weakness. According to Spitzka,[3] between the fifth and tenth years the nutrition of the brain suffers. Such children are wanting in independent thought and action. At the age of 20 to 25 the majority of onanists feel the effects most seriously. Actual nosomania may result. If such cases develop actual insanity, they can be called cases of masturbatic insanity only when the connection with the excesses is a direct one.

Spitzka occasionally observed mania, melancholia, epilepsy, stupor, and katatonia in young onanists. "There is also a form of delusional insanity, developing during and after puberty, which deserves the name of masturbatic insanity. It is chronic, has a tendency to a restless form of dementia, and in its beginning it is characterized by anxiety, fear, suspicion, and depression. Later, confusion and motor excitement occur; and, still later, rage and destructiveness" (Spitzka[4]).

Through habitual indulgence, onanism becomes instinctive; and the vain efforts of the individual to overcome it undermine his strength of character. Thus, with this victory, it becomes a genuine pathological manifestation, whether it exist alone or in connection with nervous disturbances; and then it is to be regarded as the expression of a cerebral disease. The most frequent results of masturbatic excesses are: excessive pollutions (day and night), spermatorrhœa, premature ejaculation in attempts at coitus, hyperæsthesia of the genital centres, spinal neurasthenia, congestion of the prostate, inflammation of the urethra, hyperæmia and swelling of the mucous membranes, and intense sensitiveness of the glans. In young children, besides, there may readily occur vesical tenesmus, wetting of the bed, spasm of the compressor urethræ, and urinary incontinence. Further results are urethritis, prostatorrhœa, spermatorrhœa, and impotence.

[3] Spitzka, "Self-Abuse in Relation to Insanity," The Dublin Medical Journal, 1887.

[4] Spitzka, *loc. cit.*

The neurosis of the lumbar portion of the cord leads to general neurasthenia, tachycardia, pains, præcordial distress, feelings of pressure and weight or pains in the eyelids,[1] spasm of the lids, photophobia or subjective sensations of light, diminution of the acuity of central vision, neurasthenic asthenopia, etc. To these disturbances Löwenfeld[2] adds the so-called eye-migraine.

In the female sex there are similar neurasthenic and hysterical disturbances, such as hysterical attacks, paralyses (vesical paralysis), vesical tenesmus and spasm, ovarian neuralgia, weakness of the legs, and spinal irritation. Among local disturbances may be mentioned hyperæmia of the labia minora and the vaginal orifice, desquamation of the epithelium, fluor albus, cervical catarrh, intense hyperæsthesia, pruritus vulvæ, hypertrophy of the clitoris, and irritable conditions of the uterus and adnexa.

A condition that has thus far been too little studied, and which in its significance is one of the most important and frequent results of masturbation in the female, is a form of impotence in which the orgasm no longer occurs during the sexual act, even when it is performed with several men, but in many cases may be induced *post-coitum* by masturbation. In the chapter on impotence I shall consider the matter more in detail. The above-mentioned change of character, depending upon unphysiological stimulation, may occur in woman as well as in man, and in the female it may manifest itself in a more serious disinclination to marry (Tissot).

Steinbacher[3] speaks very caustically of such a disposition: "They think they can satisfy themselves with their unnatural stimulation, and it is owing to this circumstance that so many remain unmarried, of course unconscious that health and life are destroyed by the unnatural satisfaction of their desires. One sees only too many of such erring old maids to compare with the wife, who has been the faithful companion of her husband, chaste and moderate in indulgence and moral, and the mother

[3] Steinbacher, Die männliche Impotenz, München, 1877, p. 84.

of children. It is astonishing how much better women living a full life are preserved up to an old age, and how much fresher and more joyous they appear than those old maids who suffer with all the female ills; who are so hysterical, convulsive, yellow, and bigoted; who, insufferable in their eccentricities, live in close friendship only with dogs and cats."

The question whether onanism as an etiological factor lends specific features to insanity which make it possible, from the clinical symptoms, to ascertain the particular cause, von Krafft-Ebing, on the basis of large experience, answers in the negative, stating that, where the onanism is only a symptom of disease, or where it is an exciting cause operating with a neuropathic and degenerate constitution, it exercises no influence upon the clinical form of the malady; and that it is the same when it induces the outbreak of insanity and rapidly hastens the psychical and physical degeneration. In cases of the third category, where onanism forms the predisposing causal factor of the disease, the multitude of hallucinations and the ease with which they arise are striking.

In another place[1] the same author distinguishes two forms in the pathogenesis of masturbatic psychoses:—

(*a*) A psychical, through assisting mental causes. These are spontaneous mental feelings,—remorse, shame, and fear of the results of the vice, with the painful consciousness of being unable to overcome the habit by strength of will. In such cases melancholias arise with intense hypochondriacal features in harmony with the predominating symptoms of the accompanying neurasthenia.

(*b*) The cause is somatic, through the addition of other weakening influences (insufficient nourishment, sleeplessness, physical diseases, mental and physical strain). The form of the disease here seems to be essentially conditioned by constitutional factors. If these be slight in degree, pure exhaustion-neuroses, stupor, and delusional states occur; upon a degenerate foundation are developed states of primary dementia, paranoia, and insanity with imperative conceptions.

[1] Von Krafft-Ebing, Lehrbuch der Psychiatrie, 3 aufl., p. 208.

All the symptoms occurring in the sexual psychoses are more or less those of neurasthenia, as are olfactory hallucinations of a repulsive character.

In confirmation of von Krafft-Ebing's views, Kräpelin[1] describes the psychical degeneration in the following words: "Most frequently in onanists there occurs a progressive loss of mental activity, or inability to comprehend and elaborate mentally external impressions, weakness of memory, lack of interest, or dullness. In other cases symptoms of aggravated irritability become more prominent; or strange associations of ideas, inclination to mysticism, and exalted enthusiasm; or hypochondriacal and melancholic depression. With these are associated various nervous disturbances, especially abnormal sensations, from which not infrequently absurd delusions of demoniacal or secret or physical (magnetic, electrical, sympathetic) influences are developed."

From what has gone before, it is plain that onanism is to be regarded as the causal or exciting factor in the origin and outbreak of numerous forms of mental disturbance; that is, *in all cases* with a neuropathic constitution or in connection with other assisting causes, it is capable of inflicting serious injury on the mind, often accomplishing its complete destruction. The following figures place in a still clearer light the relation of masturbation to insanity. According to Ribbing's[2] statements, the admissions of insane patients to the asylums of Sweden were:—

1883 . . .	643	cases,	of	which	25	were	due	to	onanism.
1884 . . .	704	"	"	"	19	"	"	"	"
1885 . . .	744	"	"	"	22	"	"	"	"
1886 . . .	741	"	"	"	35	"	"	"	"
1887 . . .	791	"	"	"	35	"	"	"	"
Total, . .	3623	"	"	"	136	"	"	"	"

This constitutes 3.7 per cent. In this computation those cases are also included in which onanism was only an accessory cause, and not the only exciting factor in the induction of insanity.

[1] Kräpelin, Psychiatrie, 3 aufl., p. 33.

[2] Ribbing, Die sexuelle Hygiene, 3 aufl., p. 128 (Hobbing, Leipzig, 1891).

The figures for three years in England were:—

1885 . . . 13,158 cases, of which 160 were due to onanism.
1886 . . . 13,624 " " " 163 " " " "
1887 . . . 14,336 " " " 203 " " " "

And the percentages for each year were:—

1885 . . . 1.2 per cent. (males, 2.2 per cent.; females, 0.3 per cent.).
1886 . . . 1.1 " " (" 2.0 " " " 0.3 " ").
1887 . . . 1.4 " " (" 2.6 " " " 0.2 " ").

Ellinger[1] states that masturbation was an accessory cause in 83 cases out of 383 cases of insanity. On the other hand, von Krafft-Ebing points to the fact that, in 38 of his cases of insanity due to onanism, 31 were notoriously predisposed by heredity; that in only 3 of these cases did the insanity begin before the fifteenth year, though onanism had been practiced by almost all the patients from early childhood.

Ludwig Meyer[2] observed 7 cases of onanism in girls ranging in age from 1 to 9 years. Of these, 4 remained mentally intact; in 3 children there were psychopathic symptoms, and of these 2 had a neuropathic predisposition, and the third child was born of a criminal mother and presented the clinical picture of psychical degeneration.

Dr. Peretti[3] found, among 300 male patients in asylums, 59, or 19⅔ per cent., in whom onanism could be regarded as an accessory cause of the development of the mental disturbance (Ellinger reckoned 21.5 per cent.; Dahl, 21.25 per cent.). Thirty-three out of the 59 became insane between the ages of 15 and 25; and, of all the cases admitted between the ages of 15 and 25, 45.2 per cent. were onanists.[4]

According to Peretti's statements, onanism induces a loss of the resistive power of the mind, so that the latter is thrown out of balance by a very slight additional disturbing influence. The first signs of mental disturbance are a retiring disposition, apathy and irritability, and an hypochondriacal mood. An

[1] Ellinger, Allgem. Zeitschr. für Psychiatrie, Bd. ii, cited by von Krafft-Ebing, "Ueber Irresein durch Onanie."

[3] Peretti, "Ueber Geisteskrankheit bei Onanisten," Die prakt. Arzt., 1881, xi.

[4] Comp. Lombroso's statements on page 4 of this book.

insignificant circumstance may be sufficient to induce a complete outburst of despair, fear, or an attempt at suicide. The hypochondriacal depression may go even to the extent of hypochondriacal paranoia. Pure melancholia is infrequent. The mind is weakened, and the attempts at suicide have a theatrical character. To the inconstancy and apathy are added, later, hallucinations and ideas of persecution and conceit. And the suspicion and mistrust lead to the idea of being watched, fear of persecutors, and to attacks on those supposed to be inimical. This goes to the extent of senseless confusion and violence. In silent patients who have a disinclination to employ themselves, this may go on to hallucinations. Peretti calls this "masturbatic insanity,"—moodiness, with sudden changes; excitability; phantasms of all the senses, of which olfactory hallucinations are especially frequent; fantastic ideas; epigrammatic phrases and use of foreign words in letters; increased feeling of personal importance without self-knowledge; idealistic and impractical plans for the future, both for self and humanity.

Among physical symptoms, Peretti found a blowing systolic murmur, apex-sound remarkably loud, cardiac dullness normal, changeable pulse-rate, cerebral congestions, and anæmia.

Finally, we may here allude to the well-known form of masturbatic paranoia which goes by the name "erotomania." This name of a psychical degeneration means a tendency to fall in love. A neuropathic and hysterical predisposition and cerebral diseases may favor the development of such a condition. The love of such individuals is purely platonic; it manifests itself in "enthusiasm for a person of the opposite sex who gives æsthetic satisfaction, or, indeed, sometimes for a picture or statue," etc. (von Krafft-Ebing). They are unable to gratify their passion with the object of affection. For the most part, masturbation gives satisfaction to the unbridled fancy. The patient deifies the object of desire, worships it, and bores his friends with unremitting talk of the object of his abnormal enthusiasm. Gradually and unnoticed the pathological disposition becomes actual disease. Since such persons constantly inflame their imagination, and in solitude resort to onanistic stimuli,

they frequently come to have actual illusions and hallucinations. "The delusions of love become complicated with ideas of grandeur; or they become transformed into those of persecution, in that the ideas of love may alternate with hypochondriacal fears" (Tarnowsky).[1]

Cases of erotomania belong to Magnan's[2] fourth group. In such patients the lower sexual instincts of the occipital and spinal centres are completely at rest, while perverse sexual ideas are produced in the frontal region without becoming transformed into actual sexual stimuli through the spinal centres.

The points made may be summarized as follows:—

A. Onanism in Healthy Individuals.

1. The single act of onanism, in comparison with normal coitus, is injurious to the central nervous system; for an effort of the imagination must overcome reality, thus requiring the activity and waste of nervous material which possesses a higher functional value.

2. Masturbation, when practiced no more frequently than normal coitus,—*i.e.*, with moderation,—aside from the injurious influence on the nervous system mentioned, injures the character of the individual; for it undermines the physiological relations with the opposite sex, and thus perverts one of the most important sources from which spring the impulses to exert the powers, both in individual and social existence (celibacy, etc.); and by habitual cultivation the unphysiological excitement may attain an instinctive character. This victory of an anomaly of habit over the will must be looked upon as a sign of cerebral disease. Besides, the memory-pictures cultivated by onanism may become imperative conceptions, and force the individual's sexual impulse into a perverse direction.

3. Excessive masturbation leads, also, especially where there has been premature awakening of the sexual instinct, to *spinal* and *general neurasthenia*, to *genital diseases* (pollutions, etc.), and to early *impotence;* it *injures seriously the mental*

[1] Tarnowsky, *op. cit.*, p. 58.
[2] Comp. Magnan, *loc. cit.*

development of the individual, and it may, with the occurrence of other accidental deleterious influences of slight importance *per se*, directly induce insanity.

B. Onanism in Persons of Hereditary and Neuropathic Predisposition.

As a rule, here it is practiced excessively, and in all cases it has the deleterious influence upon the nervous and mental condition of such patients mentioned under 1, 2, and 3. In accordance with the condition and age of such onanists the symptoms enumerated occur with increased intensity, lead to progressive loss of mental power, and hasten the outbreak of sexual psychoses.

Under some circumstances the diagnosis of onanism is attended with difficulties. Shame, ignorance, false notions, excessive anxiety, and the tendency to lie are often sufficient to vitiate the statements of patients. In many cases it is years before the parents have any suspicion of the child's vicious habit. In many families no attention is ever given to the matter, and, unfortunately, the number of patients who come to understand it only when they have reached years of maturity is only too great. A lady of my clientele, who had masturbated from her eighteenth year, reached the age of forty before a medical book, which accidentally fell into her hands, explained the matter to her. Another of my patients had practiced onanism eight years, and completely destroyed her nervous system, before the physician discovered the cause of her trouble.

Vogel,[1] Uffelmann, and Emminghaus think that, without exception, at a very early age children have an instinctive notion that self-abuse is wrong; for they practice it in secret, and a confession can seldom be obtained. Owing to the great prevalence of this evil habit, when there is anything suspicious in the conduct of the child, or where the mental development leaves anything to be desired, a most careful watch should be kept. The places where onanism is cultivated are schools, academies, prisons, and all places of confinement; and, too, the educational institutes for girls are not to be excepted.

[1] Comp. Vogel, Uffelmann, *loc. cit.*

Wherever children show a shy, dreamy, retiring disposition, and are slow in school and difficult to induce to rise betimes in the morning, the possibility of the existence of the habit of self-abuse should be entertained. Owing to the establishment of an automatic habit, many patients masturbate in sleep. In such cases the diagnosis has been made certain by discovery under such circumstances. One of my patients often awoke with her finger in the vagina. Spots of semen on the linen,[1] spots of blood on female linen, redness of the labia minora and the vaginal orifice, the occurrence of spinal pains and affections of the eye, fluor albus, etc., are important indices.

Grünfeld states that he has quite constantly observed hyperæmia of the colliculus seminalis. The usual symptoms are dark-red or scarlet coloring of the colliculus seminalis, with increase of its size and tenderness. According to Gyurkovechky,[2] onanistic excesses lead to flaccidity and anæmia of the penis and testicles, make the scrotum smooth, and, owing to relaxation of the muscle of the tunica dartos, cause the testicles to hang low. The meatus is reddened, the rest of the urethra pale, and the colliculus inflamed in various degrees.

The mental and physical peculiarities enumerated, and consideration of the symptoms referable to its results that have been given in detail, should make it possible to make a certain diagnosis of onanism.

The *prognosis* depends upon the health and age of the patient. Infrequent indulgence in onanism by healthy individuals may in all cases be overcome by natural sexual intercourse. Too, even where there is a habit of frequent indulgence in self-abuse in individuals of healthy constitution during the years of puberty, it is abandoned as soon as there is opportunity for hetero-sexual intercourse. Daily experience lends the best proof of this. The earlier the habit is begun, the more the mind has become implicated, and the longer and more frequently the practice of self-abuse has been indulged

[1] One of Dr. Franz Carl Müller's patients ejaculated in his stockings in order to escape detection. (Verbal communication.)

[2] Gyurkovechky, *loc. cit.*, p. 138.

in, the more unfavorable is the prognosis. But even patients in whom the vice has become instinctive have some prospect of cure when there is still a possibility of normal sexual intercourse. However, in relation to this, it must be remembered that in young girls this equivalent cannot be provided except by marriage, which does not always rest merely with the desire of the sufferers. Even with a neuropathic constitution there is some prospect of cure and improvement, as long as the neurasthenic condition has not reached the intensity of a psychosis. Where masturbation is to be regarded as the symptom of a psychosis, the prognosis depends entirely upon the fundamental disease.

The prognosis[1] of masturbatic insanity (paranoia masturbatoria), especially in elderly persons, is not very favorable, even though remissions do occur and tonic treatment is possible. However, even here cures have been reported. According to von Krafft-Ebing,[2] the prognosis of masturbatic melancholia is not unfavorable.

On the whole, therefore, the prognosis, in all cases where complete mental and sexual deterioration has not taken place, is decidedly favorable; for even in the worst cases considerable improvement is possible.

B. Satyriasis and Nymphomania.

Abnormal sexual desire is an intense disturbance in the domain of the feelings and the will, called satyriasis in men and nymphomania in women.[3] Von Krafft-Ebing regards this sexual symptom-complex as a part of a psychosis which rests upon a psychical hyperæsthesia (in hysteria, states of mental exaltation, and senile and paretic dementia). Here, too, the transitions from physiological to reckless expressions of the sexual instinct, with loss of all normal deterring influences, are gradual. Emminghaus[4] regards the immediate re-awakening of desire,

[1] Peretti, *loc. cit.*

[2] Von Krafft-Ebing, Lehrbuch der Psychiatrie, 3 aufl., p. 519.

[3] I follow, in the main, von Krafft-Ebing's exposition. Comp. Psychopathia Sexualis, p. 373, and Lehrbuch der Psychiatrie, p. 87.

[4] Emminghaus, Psychopathologie, p. 87.

after satisfaction of it, with pre-occupation of the entire attention, as abnormal.

In Magnan's[1] classification these symptoms belong to the second group,—*i.e.*, disturbances which originate in those sensory regions of the cortex which lie behind the central convolutions, where, according to this author, the zone of the desires and instincts lies, and which are influenced quasi-automatically by the genito-spinal centre as soon as the forebrain for any reason ceases to act. As examples, Magnan gives two cases of women suffering with extraordinary sexual excitement. One locked herself in her room to avoid the sight of men, who excited her desires to the utmost; the other, the mother of five children, driven by similar animal desires, would surrender herself on the first opportunity, and at last, in despair at her suffering, she attempted suicide.

Causes and Symptoms.—While married life bridles the desire, sexual intercourse with different persons increases it. The imagination creates sexual scenes which go on to phantasms of the senses with hallucinatory delirium. "Everything calls up sensual thoughts, and the lustful coloring of ideas and apperceptions is intense. Feeling and will are entirely under the control of the psycho-sexual excitement" (von Krafft-Ebing).

The man affected with satyriasis seeks to satisfy his desire at any price, and thus becomes dangerous. Here enforced abstinence[2] must be also regarded as a cause; it leads to neurasthenia, and may, with an increase of sexual desire, endanger the freedom of the will.

In animals, too, during the time of rutting, the procreative impulse overcomes all other desires and feelings, and, if it be not satisfied, leads to sexual fury and perverse acts. Thus, according to Lombroso,[3] nymphomania has been observed in cows, mares, hens, angora cats, camels, and spiders; satyriasis, in buffaloes, dogs, storks, and doves. At the time of the sexual

[1] Comp. Magnan, *loc. cit.*

[3] Lombroso, Der Verbrecher, p. 20 *et seq.*

erethism the animals are uncontrollable, and bite and kill anything that comes in their way; or they tear their own flesh, tear up the ground, etc. In dogs and monkeys onanism originates in this way.

Even violent sexual attacks upon immature animals, and sodomitic acts, have not infrequently been observed (for example, in large studs) as a result of unsatisfied sexual passion. Houzeau saw a cock attack an immature pullet. In Egypt, Lessona saw an ass perform sodomitic acts in the absence of a female. For the same reason, *faute de mieux*, sexual union occurs between the swan and goose, between the elk or buffalo and the cow, and between the dog and wolf.

Likewise in man, enforced abstinence may endanger the freedom of the will and lead to perversity in the sexual act. Thus, a case is known to me where a criminal, who had spent several years in prison, immediately after his dismissal raped an old woman of 73 years in an open field. A second case was one of my patients. He was neurasthenic and previously a masturbator, and he took a vow in a students' society to preserve his chastity, determined to abstain at any cost. After he had been able to restrain his sexual desires for some time, one evening libido came over him with all-conquering force, and clouded consciousness. He was unable to resist, and, in a confused state of mind, he followed the first prostitute he met. The result was that he had great moral anguish and fear of having infected himself; for he had performed the act without any precautions. The patient stated that he was beside himself while in this state, which resembled intoxication. A third case, in which impotence followed abstinence of five years' duration, is reported in Section II.

Tarnowsky[1] also refers the origin of satyriasis principally to sexual abstinence, especially under the influence of religious ideas. "For example, there is the confession of the Abbé de Cours, which was written by himself and published by Buffon.[2] After long struggles, fasting, and prayer, all women began to

[1] Tarnowsky, *loc. cit.*, p. 61.

[2] Buffon, Histoire naturelle de l'homme.

appear to him as if surrounded by electric light. Their glance made a confusing impression on him. Later, definite hallucinations occurred: he imagined that the governor of the court set all women after him in order to induce him to break his vows of abstinence. The visions of St. Anthony were much more remarkable than this confession" (Tarnowsky).

There may arise from satyriasis, priapism, perversity of sexual acts, exhibition, rape, lust-murder, or excessive and shameless masturbation. The genital erethism may occur in attacks, intermittently and periodically (Magnan).

Sexual hyperæsthesia occurs more frequently in women than in men. "The nymphomaniacal woman seeks to attract men to her by exhibition or lascivious conduct, and at the sight of a man she becomes intensely excited sexually, and satisfies herself by imitation of coitus or by masturbation" (von Krafft-Ebing).

Here, too, weak-mindedness is a condition which constitutes a favoring predisposition. Thus, Sollier reports: "Marie B., imbecile, aged 22; tall, of delicate build. She stutters slightly; she regards herself as sharper than any of her associates. When 13 she consorted with one of her father's servants, and since then she has associated very frequently with other men. She imagines that every man she sees, no matter what his social position, loves and wishes to marry her. She stands at the window and throws kisses to men passing. She practices masturbation excessively, and she becomes angry and excited when kept from seeking the men who happen to be in the house, in order to surrender herself to them."

One of my patients, at merely the sight or touch (pressure of hand) of a man, would become excessively excited sexually, and satisfy herself by means of ideal cohabitation or masturbatic rubbing with the thighs. For a long time the genital erethism occurred in attacks every morning,—once at my office. In spite of the presence of three male witnesses, she threw herself on an ottoman, and in hysterical convulsions masturbated several times before our eyes. In these attacks consciousness is clouded. "In women the intensification of sexual desire is expressed also

in shameless exhibition; in constant washing with water, saliva, and urine; in combing and undoing the hair; in the milder forms of self-adornment and flirting; in vacillation between forwardness and modesty or sentimentality; or in hand-squeezing, letter-writing, suggestive glances, etc." (Kraepelin).[1] The most frequent consequence of nymphomania is prostitution. Von Krafft-Ebing calls particular attention to the *rôle* of the sexual sphere in relation to physicians. Nymphomaniacal women desire gynæcological examinations, simulate retention of urine, etc. Post-menstrually, sexual desire is increased; and, according to von Krafft-Ebing, at such times in neuropathic individuals the excitement may attain a pathological degree.

In harmony with him, Neumann[2] holds the opinion that religious fervor and an inclination to indulge in religious devotions are to be regarded as clinical equivalents. "The religious idea of sexual union in the form of marriage; the relation of the Church and Christ, which is looked upon as that existing between the bride and groom; the period of puberty, when a state of feeling arising from indistinct sexual sensations is frequently expressed in religious enthusiasm; the history of the saints, in which are told the efforts to subdue the flesh; and the practices of certain sects, whose revivals and meetings often become terrible orgies, are proofs of the physiological and inner organic relations existing between religious fervor and sexual desire. Of the same nature is the impulse in maniacal virgins to make pilgrimages and do missionary work, or to become nuns or, at least, the servants of priests; and they commonly talk much of virtue and virginity"[3] (von Krafft-Ebing).

The relation of religion, lust, and cruelty von Krafft-Ebing[4] reduces to the following formula: "States of religious and sexual excitement, at the height of their development, exhibit a correspondence in quantity and quality of excitement, and therefore, under favoring circumstances, one may take the place

[1] Kraepelin, *loc. cit.*, p. 139.
[2] Neumann, Lehrbuch der Psychiatrie, p. 80.
[3] Von Krafft-Ebing, Psychiatrie, p. 89.
[4] Von Krafft-Ebing, Psychopathia Sexualis, p. 8.

of the other. Both, under pathological conditions, may become transformed into cruelty."

The diagnosis of this form of sexual hyperæsthesia presents no difficulties.

In relation to prognosis, what has been said concerning masturbation must be recalled; for the abnormal sexual desire may result from it, just as onanism may be symptomatic of hyperæsthesia; and, too, the fundamental psychopathic or neuropathic disposition must be taken into account.

CHAPTER II.

THERAPEUTIC SUGGESTION IN THE TREATMENT OF ABNORMAL INTENSIFICATION OF SEXUAL DESIRE.

The close relationship of the various forms of onanism among themselves and with those of sexual hyperæsthesia (satyriasis, nymphomania, erotomania, etc.), and the similarity of therapeutic procedures in the groups of symptoms described in Section I, make it seem best to give, in a single chapter, a comprehensive description of the curative methods and the problems which meet the physician in the treatment of the various forms in which sexual excitement is expressed.

First of all, the cause of the sexual erethism, of the masturbation and its consequences, of the premature arousing of libido sexualis, must be removed. The most important duty of parents and teachers, and one which, unfortunately, through ignorance or false modesty, is neglected, consists in prophylaxis, —in a rational sexual education suitable to the process of sexual development.

In many schools and academies masturbation and vice are actually cultivated. To-day too little attention is given to the mental and moral condition of pupils. If the lessons are learned, the principal requirement is fulfilled. That many pupils are thus ruined in body and soul is never considered. With silly prudery the sexual life is veiled from the developing children, and not the slightest notice is taken of the excitation of their sexual instinct. It is thought best to leave all to nature. In the meantime nature rises in her might and leads astray (von Krafft-Ebing.)[1] With children strict and intelligent oversight is necessary, and when there are indications of commencing onanism or other signs of premature awakening of sexual instinct, energetic treatment should begin immediately, if possible under the direction of a physician educated in psy-

[1] Von Krafft-Ebing, Psychopathia Sexualis, p. 321.

chology, and capable of the employment of suggestion. The means for the detection of onanism, for the most part at least, have been made clear in the exposition of the symptomatology and diagnosis of masturbation. Fournier's[1] work also gives more details.

The children should be observed while at play, to ascertain whether they there give evidence of sexual excitement, and whether the manner of play corresponds with the sex. Thus, playing "papa and mamma" or "being engaged" may attain pathological significance. Preference by boys for girlish games and employments, and *vice versâ* by girls, may, with indulgence on the part of the parents, in further development lead to a change of character in the sense of contrary sexuality. A typical example of this kind is offered in the celebrated case of Count Sandor (alias Countess Sarolta V.). The father of the countess allowed her from childhood to go about in boys' attire, educated her as a boy, had her ride, drive, and hunt, and said to her: "Why, you are a man; with your energy, that is at once evident." Her tutor, Daniel K., most inaptly gave her sensuality a perverse direction. The child's mother had no influence in her education.[2] With full weight given to the hereditary taint, the mental weakness, etc., it still seems questionable whether the disease of the Countess Sarolta V., without these artificial influences, would have taken the same fatal direction.

The pathological importance of educational influence in originating such conditions will be later placed in the clearest light by numerous sad cases of contrary sexuality. In youth a cure, or at least compensation, may be most hopefully sought. At the first sign of puberty children should be taught to understand the sexual relations and the results of abuse. Their fancy should be supplied with pure nutriment, and the education at school should avoid those things mentioned above which may play the *rôle* of seducer. Where there is a perverse and neuropathic disposition great care must be exercised in order that the

[1] Fournier, De l'onanisme. 4th ed. Paris, 1885.

[2] Comp. Friedreich's Blätter für gerichtl. Medicin, 1891, Heft I, p. 8.

development of the instinct be delayed as long as possible. Such experienced physicians as Moll[1] and Tarnowsky express themselves to this effect. Furthermore, separation of the sexes is to be avoided as far as possible, though the training must be devoid of all influences which lead to sexual excitement. Moreover, the relation of servants to children must be strictly watched. The cases in which infants who cry are quieted by genital manipulation are none too infrequent, as are instances of seduction of immature children to attempt coitus, onanism, etc.

The question whether indulgence in coitus is to be allowed in mature individuals has given rise to many conflicting opinions, which, owing to the importance of the subject, we cannot overlook. Several investigators, as Acton,[2] Beale,[3] Paget,[4] and Gowers,[5] contend that abstinence has no injurious effect upon the health. They permit sexual intercourse only in marriage. Augagneur[6] remarks: "In order to stamp prostitution as a crime under all circumstances, it is necessary, by unequivocal laws, to make sexual intercourse outside of the marriage relation a crime." Ribbing would combat onanism by hygienic, moral, and religious instruction. He has seen cases in which such individuals were really successful in overcoming their sad malady, "without resorting to a life of debauchery or marriage."[7] The same author says further: "Chastity harms neither mind nor body. Little as I should advise a Don Juan to give himself to onanism, I should be as far from attempting to cure onanism by means of debauchery." He pleads for the punishment of prostitution, but has to confess (p. 184) "that we are far from the state of nature, and have found no *modus vivendi* in accord with culture and its requirements." Forel,[8] who, in

general, is an opponent of prostitution, allows that there are sexual neurasthenics who are intensely excited by pollutions, but who find relief in normal intercourse." Löwenfeld[1] confirm's Forel's experience with the observation that occasional interruption of customary regular intercourse has a deleterious effect upon neurasthenic conditions. Von Krafft-Ebing has shown, though it be with a series of cases that might be considered not entirely sufficient, that a state of general nervous excitement may arise as a result of repression of one of the most powerful instincts, and that in individuals of neuropathic predisposition enforced abstinence may give rise to danger of nervous and mental diseases.[2] Thus, continued sexual excitation without adequate satisfaction of it affects the health injuriously, as occurs not infrequently in marriages between elderly men and young women. As a result of the constant excitement and hyperæmia of the genital organs, without gratification, irritable weakness of the genital apparatus and its nerve-centres may ensue. According to von Krafft-Ebing, in predisposed individuals the results of abstinence are essentially the same as those of onanism.[3] Of course, very few men possess sufficient strength of will to come off conquerors in the conflict between sensuality and reason. The vast majority, when opportunity for normal sexual indulgence is not offered, fall into the vice of self-abuse or perverse gratification of the sexual impulse, thus choosing—if non-marital, but normal, sexual intercourse may be called an evil—the *greater* of two evils.

The entire process of development of the human organism tends to put the individual into the most favorable condition for the performance of the sexual functions. The conditions of life standing in opposition to a physiological need, to an instinct possessing the same justification and strength as the desire for food, can be of no possible use to the organism, of which medical experience offers the best proof. "The idea of complete health includes complete and regular satisfaction of all the

[1] Löwenfeld, *loc. cit.*, p. 17.

[3] Krafft-Ebing, Psychiatrie, p. 209.

needs of man, and that is the goal for which hygiene must strive, and not seek to stifle one of the most important functions of the organism, like the sexual instinct. The recommendation to voluntarily destroy any function like the idea of love is a subject for the fanatic, but directly opposed to hygiene" (Tarnowsky).[1]

As long as society is not in a position to offer to every mature individual satisfaction of the sexual appetite in some generally-recognized form, as in marriage, it is senseless to oppose non-marital sexual intercourse, and, in societies for abolitionism, to seek to cultivate absolute sexual continence. To combat prostitution with police regulations and laws is but a way in which to withdraw from medical and organized legal supervision immorality and contagious disease and transfer them to the family, as Tarnowsky, in his instructive work,[2] with the presentation of abundant evidence, shows. Forel,[3] likewise with resort to statistical material, makes an opposite statement. In his opinion, secret prostitution is neither so dishonoring nor so abnormal and dangerous as public prostitution.[4] The roots of this phenomenon, which is still especially favored by the constitution of modern social life, are to be sought in the varied intensity of sexual instinct; in the varying strength of the need to satisfy it; in the variation of power of resistance in different individuals to passionate desires; in physical and mental defects of development (therefore in defect of moral sense); and, finally, in poverty and ignorance. The limitation of the evil to a minimum, which seems to every one of any knowledge of the subject both desirable and attainable, with any prospect of relative success, can only be brought about through an inner reform of society; through correct education

[1] Tarnowsky, Prostitution und Abolitionismus, Hamburg, 1890.

[2] *Ibid.*, p. 31.

[3] Forel, Zur Frage der staatl. Regulirung der Prostitution (Bremerhaven und Leipzig, Lienken), 1892, p. 18. Unfortunately, I was unable to obtain, in time to use them for this work, the books recommended by Forel, "Fiaux, Les maisons de tolérence" (Paris, 1892).

[4] In the consideration of this question, the proportion of public to private prostitution in Berlin is important. While more than 5000 prostitutes are registered, according to police estimates more than 50,000 live by prostitution. Comp. Aerztl. Vereinsblatt, März, 1892, p. 93.

of the young and the ignorant; and through an increase of facility of marriage and amelioration of conditions of life. "For the more undeveloped an individual is, the more reckless he is in the gratification of his desires." We should institute a real sexual education, and lead the matured sexual instinct, by means of the preservation of rational indulgence, into paths devoid of danger; we should make needful concession to the natural impulse; and, thus, public vice, with its results,—the unlimited spread of venereal diseases and the increasing number of crimes against morality,—would be greatly diminished, and become more and more confined to the step-children of nature (those subject to congenital viciousness). But, more than all, the foundation would be removed upon which rest masturbation and the development of the sexual instinct in perverse directions.[1]

We might thus dispel the greater evil with the lesser; for it is nonsense to think of abolishing the evil entirely. The best cure for onanism and other manifestations of sexual hyperæsthesia—with few exceptions, there can be no doubt upon this point—lies in regular sexual indulgence. The condition of society to-day, of course, allows a man much more freedom and opportunity in this direction than a woman, with the unquestioned acknowledgment that his sexual desires are much more intense than hers. "In the highly-civilized state of the social life of to-day, woman in a sexual *rôle* and serving the social and moral interests of society can be thought of only as a wife" (von Krafft-Ebing). The aim and ideal of a woman is, and remains, marriage. For, as Mantegazza justly remarks, she demands not only satisfaction of her sensual desires, but also protection and maintenance for herself and her children. However, upon con-

[1] The Committee of Management of the Prussian Society of Physicians, in its meeting of December 13, 1891, in considering the question of prostitution, touched upon the subject of sexual education. There was no difference of opinion as to the fact that the sensual impulses which lead to non-marital intercourse can in no way be restrained by public police regulations. On this occasion, attention was drawn to Lassar's deserving work, who, in two articles ("Prostitution und Geschlechtskrankheiten," Hygienische Rundschau, 1891, No. 23; and "Die gesundheitsschädliche Tragweite der Prostitution," Berlin, A. Hirschwald), points teachers to the duty of having courage to teach developing youths and warn them against the dangers of infection. The committee appointed a commission to make a report upon measures for preventing the further spread of syphilis.

sidering the obstacles to matrimony which exist in the social relations of to-day, and which, on the one hand, make marriage impossible for many women; and upon considering the extraordinary dangers and disadvantages which attend all manner of unnatural sexual indulgence, must we not acknowledge that it is better, as Steinbacher[1] says, to give to the world the healthy fruit of a passionate love than, through sins against self, against nature and health, "in invalidism and misery, to stamp youthful years with the most repulsive mark of old age?"

The strength and intensity of the sexual instinct, like moral and physical individuality, are too various to make it necessary to give a general application to the foregoing statements. Such a misunderstanding might become a welcome license and cloak for all possible expressions of vice, and it would open the door to sensuality. While one, thanks to the inherent peculiarities of his organization, can easily practice abstinence, another is led to onanism, and, as a result of it, is utterly ruined if he has no opportunity for natural sexual indulgence. Only after the most careful study of the single case can it be determined how far and in what way the sexual appetite should be satisfied. From the stand-point of sexual hygiene, the principle of the weakest force must be as determinate here as in nature in general. Therefore, the chaste youth should exercise sexual abstinence as long as he is able to restrain the instinct without injury to his health. Should he be in danger, owing to increasing strength of his sexual impulse, of onanism, of falling a victim to satyriasis, or perverse sexual indulgence, then it becomes the duty of his teacher and his physician to cause indulgence in coitus and, too, to acquaint the neophyte with precautionary measures which will guard against excesses, infection, and the procreation of illegitimate offspring which, under certain circumstances (*e.g.*, with contrary sexuality), may be hereditarily tainted. Individual sexual capabilities should determine the frequency of sexual indulgence. It is impossible to fix a normal standard. Acton allows but one act of coitus a week; Martin Luther allows two; but, on the

[1] Steinbacher, *loc. cit.*, p. 85.

other hand, the Queen of Aragon recommended six sexual acts a day. "The Talmud directs one coitus a day for a man who is well and strong and not working hard; for mechanics, two a week; while students and laborers are to indulge but once a week."[1]

Concerning the advisability and injurious effects of so-called "preventives," opinions also differ. Gyurkovechky[2] allows that only those who have some idea of what it is to have "eight children and little bread" have any right to speak for or against the employment of such measures. A means which is much lauded, and used especially in France, for the prevention of conception (known by the name "fraudiren,"—coitus interruptus), consists in withdrawing the penis from the vagina immediately before ejaculation, which then takes place. In my opinion, there is no doubt that congressus interruptus is an act harmful to health. Peyer[3] saw fourteen patients suffering with spinal neurasthenia, spermatorrhœa, neuralgia testis, sexual asthma, cardiac palpitation, etc., resulting from it. At the instant of most intense excitement the ejaculation is voluntarily postponed as long as possible; complete retreat takes place with a great expenditure of physical and mental energy. "The action of the prostatic muscle and the bulbo- and ischio- cavernosus muscles is no longer natural, unobstructed, and energetic, but modified and weakened." In a woman, the sudden cessation of friction during the height of orgasm, before the feeling of ejaculation, with its consequent sense of satisfaction, has taken place, may induce disturbances of the nervous and sexual systems.[4] In contrast with this theory of Peyer and Bergeret, Gyurkovechky states that he has seen persons who bore this procedure well.

Of all the means for the prevention of conception, the condom seems relatively the least injurious for both parties; and it affords relatively the greatest protection against infection and pregnancy. Therefore, as does Gyurkovechky,[5] we can recommend to our patients a well-made, elastic condom.

[5] Gyurkovechky, *loc. cit.*, p. 144.

In the foregoing, the fundamental features of sexual prophylaxis have been sketched in all its most essential points, in accordance with the principles of hygiene. To emphasize it again, the most important principle is, and remains, individualization. No prudery, no false modesty, should keep us from giving the same care and attention to the most powerful of natural instincts which everybody gives to other physical functions,—such as is given to nutrition! Whole libraries are written about appropriate and healthful diet, but there is hardly to be found a single book resting on a strictly physiological basis concerning the care of the sexual functions! Numerous popular and error-breeding works and the products of an extreme asceticism are the only substitutes that have yet been offered to youth seeking knowledge.

A sexual education which takes account of all the physiological needs, in all therapeutic measures directed against psycho-sexual disorders, is an important and indispensable part of the psychical treatment. The application of suggestion is for the physician an excellent means of methodically disciplining, in the most effectual and quickest manner, the patient's feelings in accordance with these educational measures. Above all, this is true in those cases in which psychical treatment in the non-hypnotic state progresses slowly or is ineffectual. For this reason, in this book, sexual education, as an important part of psycho-therapeutics, must be considered.

Before we pass on to therapeutic suggestion in its narrower sense, we may review briefly other customary methods of treatment, since it is often necessary to use combined means. Here we may limit ourselves to a review of the most necessary measures, with citation of several excellent works on impotence, neurasthenia sexualis, etc., which give other methods of treatment in detail.

We have an important aid in *hygienic measures.* The patients should lead a life tending to strengthen them. The diet must be nutritious and unstimulating, and digestion must be regulated. Meats must be taken moderately, and there must be great moderation in the use of alcoholics. Supper should be

taken three hours before retiring. Onanists should not sleep more than seven or eight hours, and they must be compelled to rise early. Persons who masturbate automatically in sleep are to be provided with appropriate mechanical devices for arms and feet to prevent the act, and the genitals should be protected with a proper bandage.[1] Above all things, the onanist must avoid solitude and have no opportunity to dream. The imagination must be given healthful food, and the patient must be usefully employed from morning until night. Rational gymnastic exercise and long walking tours lessen the excitability of the sexual centres. In addition, there should be massage, swimming, etc. In the choice of diversions, according to the individual, such things are to be scrupulously avoided as tend to excite the imagination to psychical onanism. First of all, the cause of the habit is to be removed: remedy a phimosis; obviate other conditions, induced by bodily conditions or external circumstances, which cause excitement, pruritus, etc. The results of onanism—spermatorrhœa, etc.—are to be treated locally.

Hydrotherapeutic procedures are to be recommended in almost all cases of sexual hyperæsthesia. Thus Caspar[2] recommends cold baths, followed by cold douches to the spinal column; also cold rubbing with wet towels. Prolonged warm baths have a calmative effect on the nervous system in cases of satyriasis and nymphomania. Concerning the use of sponge-, shower-, and douche- baths, and hip-, steam-, and sea- baths, compare Gyurkovechky,[3] Beard,[4] Löwenfeld,[5] and Winternitz.[6]

[1] For description of mechanical means for the prevention of masturbation, compare Fournier, De l'onanisme, Paris, 1875. This author gives a long list of devices; for example,—shirts that are closed in various ways, trousers or drawers without openings, etc. Mantegazza, Fournier, and Porro recommend the subcutaneous insertion of a ring in the prepuce (near the frenulum). The wound heals and the ring is allowed to remain. Mechanical irritation causes tension at the base of the glans, and gives rise to pain. Inflammatory œdema follows attempts at onanism, and attracts the attention of the parents. According to Mantegazza, the ring is applicable to girls. Here the ring must be inserted between the middle and superior third of the labia majora, so that the labia are brought in contact with each other by the ring at the point indicated. Compare Mantegazza, Die Hygiene der Liebe, 3 Aufl., Jena, Costenoble, p. 82. But no mechanical devices can overcome psychical onanism.

[2] Caspar, Impotentia et sterilitas virilis, München, 1890, p. 104.

[3] *Loc. cit.*, pp. 158, 160.

[4] Sexual Neurasthenia.

[5] *Loc. cit.*, p. 154.

[6] Die Hydrotherapie, 1879, Bd. ii.

Too, treatment with sounds, injections, rectal treatment, and, in females, irrigations and other local applications, may be necessary.

Various forms of *application of electricity* in the conditions which result from onanism, especially neurasthenia, are highly recommended by all authors in the form of faradization as well as of central galvanization (Beard and Löwenfeld). Almost every author has his own method, which may be learned by consulting the special works. Moll's work,[1] which lately appeared ("Is Electro-Therapeutics a Scientific Remedial Procedure?"), should be consulted; and also the controversy of Möbius and Eulenburg[2] concerning the *rôle* of suggestion in the application of electricity. Moll declares that, though he does not regard electro-therapeutics as a scientific remedial procedure, it is still the physician's duty, even though it be based only on empiricism, to use electricity in appropriate cases.

Among the articles of the materia medica, the various preparations of bromine have a calmative effect upon the genito-urinary system. Other known anaphrodisiacs are: belladonna, lupulin, camphor, opiates, and salicylic acid with prolonged use. On the other hand, cantharides, phosphorus, and atropine exert an exciting effect on the genitals; and for this purpose Hammond[3] recommends strychnia.

Psychical Treatment in the Non-Hypnotic State.—In the last part of this section we come to psychical treatment in general, in so far as it has not been considered with reference to sexual hygiene, and to therapeutic suggestion in its strict sense as the most important part of it. All authors that have written on onanism, sexual neurasthenia, etc., agree concerning the effect of psychical treatment. In the non-hypnotic state, with due consideration of the individual concerned, such treatment must first be in the direction of an explanation to the patient of the nature and the results of his disease. To convince the patient that he or she has become the victim of an abnormal,

[1] Berliner Klinik, Heft 41, November, 1891.
[2] Berliner klin. Wochenschrift, 1892, No. 8.
[3] *Loc. cit.*

dominating impulse, whether an onanist or a nymphomaniac,—that is, self-knowledge,—constitutes an important step toward improvement. The mistrust of the patient is to be removed and his hope awakened by analyzing his case for him. All exciting influences, like obscene reading, bad company, pornographic pictures, etc., capable of exerting a detrimental influence on the patient's imagination, must be avoided. An attempt must be made to win the entire confidence of the patient, to strengthen his self-reliance, and to overcome his erroneous ideas by repeated explanations and educational means. The patient must learn to control himself, to strengthen his will, and, by practice, gradually become master of his sexual impulses. The diversion of his attention plays a *rôle* the value of which should not be underestimated. Experience teaches that mere diversion of the mind, even during coitus, may overcome erection. Cases of impotence due to mental preoccupation are not very infrequent; it occurs with especial frequency as a result of intense thought on abstract subjects. Broussais[1] asserts that mathematical studies diminish sexual power. Grimaud de Coux[2] and Martin Saint-Ange recommended the study of mathematics as one of the most effectual means of repressing intense libido sexualis. These authors report a case in which a celebrated mathematician was always restrained from completion of the act of coitus by the sudden recurrence in his mind of problems of geometry or proportion with which he had been occupied during the day. Hammond[3] reports the same thing in the case of a card-player who, during cohabitation, always was seized with the thought of a technical manipulation of cards, which destroyed his sexual power. Active business operations make a large demand upon thought, and thus the sexual impulse is repressed.

Rosenthal[4] and Bernheim[5] speak in favor of the "larvated" form of psycho-therapeutics in the non-hypnotic state and for

[1] Cours de phrénologie, Paris, 1826, p. 783.

that form which excites pain. Such forms depend, for their effect, upon the excitation of ideas of cure, by means of intense sensory impressions, such as cold douches to the genitals, faradic penciling, or other instrumental procedures, and fright and fear (with children). The means used may be medical, mechanical, electrical, and religious[1] and mystical. The patient's thought with regard to the cure should be altered. The patient, though seemingly passively, in reality brings about the cure actively. A quiet demeanor on the part of the physician that invites the confidence of the patient, an understanding of the latter's individuality, and great patience are indispensable.

The principal means of psycho-therapeutics, in the non-hypnotic state, seem to gain more and more recognition, especially among such investigators as undervalue the effects of hypnotic procedures. The various mechanical and other remedial procedures, above alluded to, may unconsciously (without the knowledge of physician or patient) exert a suggestive influence,—a statement which the effect of the measures themselves does not controvert. Löwenfeld[2] believes that quinine, iron, arsenic, and the bromides, as remedial agents in obstinate cases of nervous weakness (of sexual origin), are effectual for the most part through suggestive effect; and he recommends static electricity as an excellent means of inducing psychical effects.

In the various forms of psycho-therapeutics, psycho-therapy by suggestion forms the most effectual remedial measure. It fulfills all the requirements of such treatment, and gains a more speedy and surer entrance into the patient's mind than is possible to any of the other forms. Therefore, it may be regarded as an abridged and condensed procedure possessing all the advantages of psycho-therapeutics. With von Krafft-Ebing, among the authors repeatedly mentioned in this work, Caspar[3]

[1] There is no doubt, in spite of numerous exceptions, that a strict religious education with many persons is an excellent prophylactic against sexual errors. Compare the brochures of Römer, previously mentioned.

[2] *Loc. cit.*, p. 152.

[3] *Loc. cit.*, p. 98: "I doubt not that suggestive therapy (in impotence and sexual disturbances) will give invaluable results."

and Löwenfeld[1] principally speak in favor of hypnotic suggestion in sexual neuroses.

Tessie's[2] remarkable experiment shows that erotic feelings can be awakened and removed by hypnotic suggestion. To an hypnotized subject he suggested: "The right ring-finger represents lust; the left, chastity. He awakened the patient without speaking, and then pinched the right ring-finger. At this the patient gradually became erotic, and he overcame the feeling by pinching the left ring-finger. Tessie forgot to remove this suggestion. The next day the patient presented himself, worn out and scarcely able to stand. The patient stated that the preceding day he met a friend who pressed his right hand, and a few minutes afterward he was taken with an overmastering desire for coitus. He noticed that this desire arose from the right ring-finger, which he had pressed many times during the twenty-four hours. Excited by this means, he had practiced onanism several times and had coitus several times during the night; and on the day on which he came to Tessie he had had several ejaculations, for on the way he had pressed his right ring-finger."

The physiological basis of therapeutic suggestion in hyperæsthesia sexualis is demonstrated by those experiments that show the possibility of voluntarily increasing and diminishing by suggestion vasomotor and secretory processes, as well as emotions, impulses, and mental affects. Dreams of a sexual content, which, as is well known, may induce ejaculations, may be called physiological auto-suggestions, and are analogues of the suggested dream in hypnosis.

Notwithstanding the insufficiency of the material at hand, the collection of previous experiences answers this question in the affirmative.

[1] *Loc. cit.*, p. 157: "In hypnotizable persons hypnotic suggestion is capable of the greatest service. In the case mentioned above, of a girl who, after abandoning masturbation that had been long practiced, suffered with occasional sleeplessness and greater sexual excitability, a single hypnosis with appropriate suggestions was repeatedly successful in giving sleep and freedom from sexual excitement for weeks at a time. Still, this patient was an excellent somnambulist, who could be placed in deep hypnosis in a few seconds. In other cases in which only slighter degrees of hypnosis could be secured, the results were not so brilliant."

[2] La France, 1889, p. 109, cited by Caspar, *loc. cit.*, p. 99.

Charles Richet[1] demonstrated that it is possible to induce ejaculation by merely awakening a belief that coitus is being performed. Sexual psycho-pathology, in ideal cohabitation, presents analogous examples of orgasm induced by auto-suggestion. Merely the direction of the attention to the performance of coitus, in association with lively images of sexual content, induces vasomotor changes in the genitals, as any one may demonstrate on himself. Purely as a result of idea, excitation of the dilators of the penis occurs, exactly in the manner that blushing and pallor are brought about by psychical impressions.

While without hypnosis the vasomotor nerve-centres may be intensely influenced by ideas, in hypnosis there is a marked increase in the intensity of this physiological manifestation, which may attain overpowering force. This occurs as a result of the removal or weakening of the regulating inhibitory mechanisms,—associative and opposing ideas. Natural reaction, *i.e.*, the transformation of idea into a certain form of movement, may take place with more energy and rapidity. Vasomotor effects induced by suggestion may, in certain persons, become so intense as to cause hæmorrhages, menses, etc. Forel[2] shows that it is possible to induce and prevent erection by suggestion, and that thus pollutions may be controlled. In the same way, the well-known physiological fact of the waking state that simply ideas, feelings, and impulses call up desires or inhibit them,—*e.g.*, appetite (at sight of food), thirst, joy, excitation of libido sexualis at sight of a woman, etc.,—is intensified in hypnosis. In an hypnotized woman I was able to induce the greatest expressions of joy by suggestion, and at the height of the emotion change it by the same means to the opposite extreme of feeling, *i.e.*, to sadness with passionate weeping. In a similar manner, we may affect the psychical part of the sexual mechanism more easily and enduringly in hypnosis than in the waking state.

The memory-pictures, which in all psycho-sexual patients are influential in inducing sexual feelings, may be weakened in

[1] Moll, Der Hypnotismus.

[2] Forel, Hypnotismus, 2 Aufl., Enke, Stuttgart, 1891, p. 56.

their effect or rendered impotent by suggestion. In onanists, for example, we may successfully suggest repentance and open confession (*e.g.*, in hypnosis to control the statements made in the waking state), and thus successfully oppose their weakness of will, in so far as it does not arise from deep, inherited constitutional conditions. The impulse to self-abuse, or the pathological impulse to homo-sexual intercourse, may have become a habit which imperatively and unconsciously controls the patient, he being unable to resist it. In such cases we must strive to combat the pathological auto-suggestion in accordance with its manner of origin, for habit is to be regarded as auto-suggestion. The ideational excitant imparted in therapeutic suggestion must be intensified by repeated hypnotization, until it acts automatically from the brain and has become a habit. Through consequent discipline it finally becomes a habit having the same force as the pathological auto-suggestion, and thus compensates the central pathological excitant. Unfortunately, hereditary disposition sets a limit here also which therapeutic efforts cannot pass. In correct and skillful use of ideas induced in hypnosis lies the power of suggestion as a pedagogic aid. In the same way we are able to effectually combat the pathological results which manifest themselves in neurasthenic symptoms and alterations of the normal subjective feeling.

The nearer the anomaly approaches actual mental disease, the more difficult the physician's task becomes. The disturbance of attention makes hypnosis impossible, and the influence of the operator, unfortunately, is not always sufficient to equal the power of the auto-suggestions which in many patients arise from organic conditions. As we have seen from the foregoing consideration, the ideas implanted in the brain during hypnosis correct the disturbances of the sexual life, the causes of which in a great number of cases are psychical, and the secondary results of which manifest themselves in symptoms of functional weakness of the nervous system; or the psychical factors play the principal *rôle* in the disease. In comparison with other indirect remedial measures, we may characterize therapeutic suggestion in manifestations of sexual hyperæsthesia from

psychical causes as the most direct remedial measure, and one which attacks the evil at its root. In cases of onanism no other method of treatment can be compared with therapeutic suggestion in rapidity and certainty of action; psychical therapeutics in the waking state often does not succeed where hypnotic suggestion is successful. Since onanists are, as a rule, children, it is very easy to see that the categorical command of the suggestive impulse, owing to their sensitiveness to hypnosis, is much more effectual than the circumstantial procedure in the waking state. Besides, the latter method, in the matter of self-knowledge, strength of will, etc., makes demands upon the juvenile mind which reach beyond the mental horizon and ability of many children. After these theoretical considerations there can no longer be any doubt that psycho-therapeutics by suggestion is destined in the future to play the principal *rôle* in the treatment of onanists, while former methods of treatment are to be employed only for the sake of completeness.

In a more limited sense, the same is true of satyriasis and nymphomania in their milder forms; severe cases and those due to organic conditions are to be treated in asylums as cases of insanity, where in such cases suggestion may also possibly prove of benefit. Practical experience fully confirms our opinion based on pathogenesis.

CHAPTER III.

CASES ILLUSTRATING THE SUGGESTIVE TREATMENT OF SEXUAL HYPERÆSTHESIA.

TWENTY cases from the experience of others and myself follow, which, with the exception of Case 9, are published together for the first time from the manuscripts of the authors. The grouping of the cases corresponds with the foregoing classification.

ONANISM BY MEANS OF TACTILE IRRITATION.

(Cases 1 to 16,—1 to 9 by other authors; 10 to 16 by the author.)

Case 1. *Onanistic Inclinations in a Child Overcome by Hypnotic Suggestion, without Relapse. Reported by Dr. Liébeault, Nancy.*— L., a boy aged 3, in July, 1887, was cured of his onanistic inclinations in three sittings. He passed into light sleep. In September, 1888, relapse. I cured him of his vice by suggestion in eight sittings. According to his grandfather's statement, there has since been no relapse.

Case 2. *Onanism in a Boy Cured by Hypnotic Suggestion. Reported by Dr. Liébeault.*—Another boy, aged 7, passed at once into somnambulism, and in five sittings was cured of his onanistic tendencies. He has not been brought for treatment again; hence, I hold his cure to be lasting.

Case 3. *Masturbation and Enuresis Nocturna in a Girl Cured by Hypnotic Suggestion. Reported by Dr. Liébeault.*—A., aged 8, female, masturbated by touching the genitals with her hands from early childhood, and suffered with enuresis nocturna. After three hypnotic sittings (somnambulism) the evil habit and the enuresis disappeared. Has she relapsed? I have heard nothing of it. Still, to avoid relapse in such obstinate cases, from time to time they should be treated by hypnosis as a prophylactic measure.

Case 4. *Onanism and Chorea Improved by Suggestion. Reported by Dr. Liébeault.*—X., a boy aged 9, was seduced to onanism by an old woman. He was also subject to choreiform movements. Suggestive treatment improved him from sitting to sitting. Unfortunately, the treatment was interrupted, and I could not learn whether he was completely cured.

Case 5. *Unsuccessful Hypnotic Treatment of a Weak-minded Onanist. Reported by Dr. Liébeault.*—B., a young man aged 30, became weak-minded at the age of 12, and had masturbated for years. In spite of all

treatment, he continued the vice. At the first attempt at hypnosis he passed into deep sleep. Notwithstanding the fact that for months I daily subjected him to treatment by suggestion, I obtained no result.

Case 6. *Masturbation in a Girl Cured by Suggestion. Reported by Dr. Wetterstrand, Stockholm.*—A girl aged 26, school-teacher from the province, was given to masturbation from childhood. In three weeks of treatment she was cured by hypnotic suggestion. W. could not ascertain whether she had since married.

Case 7. *Temporary Improvement by Hypnotic Suggestion in a Boy, Predisposed by Heredity, Suffering with the Habit of Onanism. Reported by Dr. Bernheim, Nancy.*—A child aged about 8, Russian, was brought to me by his mother three years ago. The boy had masturbated for years. This tendency was probably hereditary; for, as a mature man, his father was unable to overcome this evil habit. The child was pale, seemed lymphatic and nervous, and had been badly trained. It was easy to produce hypnosis deep enough to leave no memory of it after waking. But during the hypnosis he threw and turned himself about. Quieting suggestions were without effect. I treated him three or four weeks continuously. During this time he seemed to have abandoned his habit; at least, his mother, who watched him carefully, noticed nothing. But after interruption of the treatment he renewed his habit. All medical, hygienic, and other treatment remained futile.

Case 8. *Lasting Removal of Habitual Onanism by Hypnotic Suggestion in a Boy. Reported by Dr. Bernheim.*—X., aged 8, a pupil at Bar-le-Duc, was brought to me by his father, April 9, 1891, on account of habitual onanism, which he had practiced for three years. A boy of 16 had taught it to him. Seven months previously his parents had discovered his vice. They surprised the child *in flagranti*, while he was apparently sleeping in bed. The boy masturbated as often as five times in a night; as a rule, three times, and as often during the day. Ejaculation began in the preceding October. Many methods of treatment had been tried (bromides, threats, baths, removal of all excitement, etc.). For three months he had drunk only water. Nothing had been successful. The child seemed very intelligent, obedient, and well trained. For two months it had been noticed that his mental powers were failing. Since then he had not been sent to school; for, in spite of the watchfulness of the teacher, he masturbated. Still, the patient had a desire to be cured. But the passion was stronger than his will, which was powerless. According to his statement, the act was performed in sleep at night involuntarily. Whenever he desired to enter the closet, he requested his father to accompany him, since, otherwise, he could not withstand the temptation to masturbate. Aside from rötheln and scarlet fever, X. had had no diseases. He had never shown symptoms of nerv-

ousness, and was devoid of nervous heredity. At the first sitting, on April 9th, I placed him in deep sleep, with amnesia on awaking. I suggested to him that neither by day nor by night was he to have a thought of touching himself, and that he would be able to withstand all temptation. I repeated these suggestions every day until the 23d of April. From the first sitting the child continued cured. The thought to masturbate did not occur again (according to his own statement). April 11th he weighed 44½ pounds; on April 13th, 45 +; April 16th, 46 +; April 21st, 47 +. Before his departure, I suggested to him to write me concerning the duration of his cure. I received a letter dated May 23d. The cure remained lasting. At that time he had gained slightly in weight. Some months later I met the family physician. According to his statement, the cure had continued lasting. The child, previously shy, and who would never look at the doctor, then met him without embarrassment, with open mien and a good conscience.

Case 9. *Moral Perversity (and Onanism) Cured by Hypnotic Suggestion. Reported by Dr. Aug. Voisin*,[1] *Paris.*—A boy, aged 16, was brought to me June 9, 1888, with the desire that I cure him of evil instincts by hypnotism. At the age of 13 he had tetanus. Since that time he had suffered with nystagmus and had stuttered; but before that, and since his sixth or seventh year, his evil peculiarities of character had made him unendurable. He lied, stole, was disobedient and vicious. His evil instincts had grown worse from year to year. In several schools he could not be endured. All efforts of his mother to improve him were vain. It was impossible to get him to take the first communion. Of late years he had stolen more frequently, and led a vicious life. He stole from his mother in order to run after girls. Onanism in him was a passion to which he gave himself in the same room with his mother without shame. He imagined that he loved evil, and stated that he felt no remorse. His parents consulted a great number of teachers and priests without effect.

The discipline of the houses of correction was too weak for him. Finally, I was consulted in the matter.

At the first examination, the existence of convergent strabismus of the left eye, nystagmus, and stuttering was ascertained. Ears, hands, and feet normal. No tumefied glands; no bronchocele. The tongue was deflected to left when protruded. He read only with difficulty, and had but an elementary knowledge of geography. Memory good, on the whole.

June 9th, first hypnotic treatment. Fixation of a shining ball that was hung over his head, in connection with sleep-suggestions, induced hypnosis in the fifth sitting. After the occurrence of sleep I began to combat the tendency to steal and to change his character by suggestion.

[1] Dr. Aug. Voisin, Médicin de la Salpêtrière, "Un cas de perversité morale guéri par la suggestion hypnotique," Revue de l'hypnotisme, 1888, p. 130.

After the first sitting he ceased to steal, and his character underwent a favorable change. The treatment was continued every third day, and the suggestions were directed in turn against his vicious character, his evil instincts, onanism, and his immoral habits.

July 6th the young man was like a different person. All thought of doing evil had disappeared and given place to the best principles. His disobedience and incorrigibility gave place to a desire to be pleasant to his mother. So to speak, he was no longer the same young man, and he expressed to me his delight at the change.

On October 20th, after absence of six weeks, the cure continued, though there had been no treatment in the interval.

The further continuance of the cure and the fact of a complete inner transformation were confirmed by a letter to Dr. Voisin, based upon observation, which was written by a former teacher of the patient after his discharge.

The foregoing case seems to me worthy to be reported, because the onanistic tendencies are to be regarded as a symptom of the boy's character. With the successful and lasting change of character the root of the evil was removed. This remarkable result offers hope to such unfortunates in whom masturbation is favored by hereditary predisposition.

Case 10. *Personal Observation. Successful Hypnotic Treatment of an Onanist in Three Sittings.*—V., aged 14, pupil of a foreign school, was sent to me, April 20, 1889, with a letter from his mother. Parents healthy; V. had had no severe illnesses; moderate left inguinal hernia; truss. Genitals normally developed. Patient is suspected of masturbation, and after rigid questioning he confessed his vice. For a year or two he had practiced it frequently (seduced to it). Unfavorable effect on the nervous system. Remarkable and increasing dullness in school. Sleepy, inattentive, dreamy, etc.

During his stay of nine days in Munich the patient could be hypnotized only three times,—on April 22d, 24th, and 27th. He passed into somnambulism; suggestions to remove his vice. During the treatment the patient made no attempt to masturbate. He stated that he felt disgust, and promised me repeatedly to masturbate no more.

April 28th he returned to school. After the three sittings I could only discharge the patient as improved, the more because it was clear that the unavoidable stimulus of seduction would still influence him. I called the attention of his relatives to the probability of relapse, and explained that a perfect cure might be obtained by frequent regular repetition of the procedure, together with strict control of the patient.

In September, 1891, I learned that further treatment of the patient for his vice had not been necessary. Influenced by the psychical treatment in 1889, probably, he had entirely abandoned the evil.

Case 11. *Personal Observation. Temporary Improvement, Lasting Six Months, of an Onanist by Hypnotic Treatment.*—Patient aged 18, without hereditary or pathological antecedents. Given to onanism since his thirteenth year; masturbates daily, usually mornings. He rises late, has no desire to work, and suffers with pressure in the head and pain in the back. Dreamy; memory weak. He had fallen behind in school. Depressed state alternating with causeless intense excitement (violent outbursts of anger). Patient was first hypnotized on February 18, 1889. Complete hypotaxis. Cataleptic symptoms. Energetic suggestions to give up the abnormal impulse and satisfy his desires with women. Up to March 11th, masturbation but once (previously daily).

Gonorrhœa from second coitus, which was cured by injections and bougies in the course of the following weeks. Up to May 20th the patient was hypnotized twenty-six times, at first daily, then two or three times a week, and finally every week or fortnight.

On May 20th the patient was discharged as essentially improved. The complaint mentioned had disappeared entirely of late. Mood agreeable. No onanistic relapses, but from time to time normal cohabitation. He stated that family circumstances made it very difficult for him to satisfy his libido regularly. After six months the patient reported that he was well. On my last inquiry (two years after) he reported that he had relapsed.

This relapse cannot alter the fact that a decided improvement was brought about by the treatment in 1889. If the patient and his relatives did not take pains to carry out proper sexual hygienic measures and provide prolonged medical control, the relapse can only be ascribed to this failure; the result of therapeutic suggestion is not altered by it.

Case 12. *Personal Observation. Lasting Cure of an Onanist by Hypnotic Suggestion, and his Preparation for Examination by Suggestion.*—B. S., medical student, aged 20. Parents and other members of family healthy. No diseases except measles and chicken-pox in early childhood. Moderate skolio-kyphosis due to rachitis treated surgically. Sexual desire began in his twelfth year; gratification of it since that time by masturbation, as a result of seduction. Patient had never felt the need of hetero-sexual intercourse. Though this constituted the content of his sexual imagination, he had never had the courage and self-confidence to substitute coitus for onanism. The patient still masturbated at least three times a week. For a long time S. had noticed the injurious effect of this sexual condition upon his nervous system. Great inclination to dream, languid appearance, retiring habits, anxiety. Great lack of energy and diminution of mental activity. S. often remained in a doze mornings until 11 o'clock, and, as a rule, rose late. Remarkable inattentiveness and mental weakness, which had made itself felt very unpleasantly in the preparatory studies he was making in the face of

his approaching medical examination. He looked forward to the examination with anxiety, convinced that he could not pass it. The patient was very easily confused, and had lost self-confidence. Great timidity. He consulted me not about his onanism, but to have his courage and confidence strengthened for the examination by suggestion. In other respects the patient presented no noteworthy physical or mental abnormality.

June 17, 1891, first hypnotic attempt. In spite of unconscious resistance to the suggestive sleep, in a few minutes he passed into the second stage (Forel), catalepsy, with inability to interrupt it voluntarily. Complete hypotaxis, but consciousness retained.

Suggestions: 1. Repugnance for onanistic manipulations. 2. Inclination for coitus and complete faith in its successful performance. 3. Indifference about the result of the examination; perfectly-clear head during it, and the presence in mind of knowledge acquired. 4. Post-hypnotic feeling of well-being.

June 18th S. joyfully told me that the previous day he had ventured to attempt coitus for the first time, and had succeeded perfectly. No thought of onanism since. Increased self-confidence and belief in the cure.

Repetition of the treatment and suggestions of June 17th.

June 19th, three hypnotic sittings. No onanistic inclinations. Voluntarily the patient gave me his word of honor that he would never masturbate again, and set out for Austria to take his examination at a provincial university.

June 26, 1891, he wrote in a letter: "It is my pleasant duty to inform you that your efforts in my behalf were crowned with the best results to-day. I passed my examination *with distinction*. For this I have to thank only your excellent application of suggestion; for what you suggested to me was fulfilled perfectly: I had a clear head and not the confusion which had previously hindered me in study and recapitulation of what I had learned. Since I had studied much, and, owing to the suggestion, was certain of being able to apply what I had acquired at the proper place, I went to the examination with a feeling of indifference. By such a result my faith in hypnotism was greatly increased. As for my former vice, I can assure you that, since I had the honor to be treated by you, I have not masturbated and have felt no desire to do so. I now have the best prospect of inducing my chamber-maid to accede to my desire. We kiss each other, etc. I mention this merely to show you that in this direction the suggestion has had the greatest success. With very kind regards, I remain, most respectfully, your ever-grateful patient."

Early in August, S. again presented himself. He had not masturbated again. He was better physically and mentally, and from time to

time was accustomed to visit the *demi-monde* to gratify his lively sexual desire. I think I may regard the patient as *cured* of onanistic tendencies.

The hypnotic treatment, owing to the youth of the patient, undertaken sufficiently early, removed in only three sittings the fully-developed masturbatic excesses that had existed for seven years. Besides, there was the remarkable influence of suggestion upon the mental condition of the patient during his examination.

It seems very questionable whether psychical treatment in the waking state (which, as Rosenbach[1] has shown in his instructive work, must, as a rule, avail itself of indirect methods,—medicaments, mechanical and electrical means) would have been attended in the foregoing case, in the same brief period, with a similar prompt result. To overcome a man's one-sided thought and feeling, that had been habitual for seven years, by means of awakening hopeful ideas and persuasion, would at least be much more tedious than to remove the injurious associations by means of hypnotic suggestion, even if the first method were possible in a medically-educated skeptic.

Case 13. *Personal Observation. Successful Suggestive Treatment of an Onanist.*—H., aged 24; mother gouty, father nervous. A paternal great-uncle a drinker; other members of family healthy. At the age of 8 patient had typhoid fever, and was nervous after it for two years. The patient learned to masturbate as a result of itching of the genitals induced by a superficial sore on the prepuce. Touch induced erection, and further friction ejaculation. The patient is very powerfully built, tall, and, aside from phimosis, presents no abnormalities or anomalous symptoms.

For two years he masturbated daily, and during the act thought of coitus with a lady to whom he was attracted. Masturbation was always accompanied by the same idea. Unfavorable effect on the nervous system. The patient likes to lie abed late dozing. Memory and understanding suffered. Headache, loss of energy, depression, irritability, and pressure in back of head were added. The neurasthenic troubles hindered his studies. Since learning its meaning, onanism was less frequent, at times only three or four times a week. In a students' society he had taken a vow of chastity, and he had numerous inward struggles between moral thoughts and sensual excitement.

Owing to the fact that his ability to work had diminished during the last two months, he had taken an antineurasthenic hydropathic cure, by which his general condition had been improved. But his onanistic tendency is unchanged. During the last week he had masturbated three times; pollutions occurred at night once or twice a week.

[1] Comp. "Ueber psychische Therapie innerer Krankheiten," Berliner Klinik, July, p. 23 (Fischer, 1890).

On the evening of November 20th, when a prostitute addressed him, his sensual excitement overmastered him as never before, overcame his resolutions, and clouded his brain; so that, as if "drunk or in a dream," and devoid of will, he followed her and had coitus for the first time. When he awoke from his dream, severe self-accusation, remorse, fear of infection. On the morning of the 21st H. consulted me to learn whether he had been infected. The psychical impressions left by the events of the day before were so strong that at the examination the patient sank into a chair, almost fainting and disheartened. Encouraging words and explanation of the sexual relations quieted him somewhat. The patient then came under my treatment, which consisted of three measures: (*a*) operation for phimosis; (*b*) antineurasthenic therapy; (*c*) removal of onanistic inclinations by suggestion.

I began with *c* on November 24th, after I had explained matters to the patient, considering his religious convictions and scruples of conscience. The duty of the physician required him to warn against onanism; normal intercourse performed with prostitutes, with measures against infection, was the lesser of two evils, but the physician had no right to oppose the patient's moral principles by recommending coitus. The patient, therefore, must struggle against his sexual instinct, and the struggle could be lightened by hypnotic suggestion; if, however, the patient could not thus overcome it, coitus was to be preferred to masturbation.

November 24th, first hypnotic attempt. Deep somnolence (stage II). Imperfect memory. Suggestions against onanistic thoughts and depression. Strengthening of self-confidence and resistive power by suggestion. Excellent result. After hypnosis and during the following days the patient felt well and had no inclinations to onanism. Spirits raised.

Repetition of the procedure on November 28th and December 1st. The patient passed at once into somnambulism.

December 30th, operation for phimosis. My intention to perform it during hypnosis was not carried out, because the patient was too excited. In all the patient was subjected to twelve sittings; was discharged toward the end of January, 1892, as cured. Up to that time it had been unnecessary for him to repeat coitus. He has been under observation, and there has been no relapse so far.

Case 14. *Personal Observation. Onanism and Neurasthenic Troubles. Lasting Cure by Suggestion.*—N., aged 28. Father drinker, uncle and brother contrary-sexual, sister hysterical. Neuropathic disposition due to hereditary taint. Patient stated that since his twentieth year he had had pulmonary hæmorrhage five times. Until three years ago he had lived abroad, where there had been small opportunity for hetero-sexual intercourse, on account of the small number of women and the diseases

among them. He recovered from his pulmonary affection, and after his twentieth year gave himself to masturbation, as he said, *faute de mieux*, from enforced abstinence. Since that time—for eight years—he had masturbated several times a week; habit continued. According to his statement, severe mental strain attending disappointed affections, together with the psycho-sexual anomaly, had essentially contributed to the development of the present state of nervous exhaustion. The patient had become conscious of his abnormal condition about a year before.

Mental depression with melancholic paroxysms of weeping, bodily weakness, no desire to work; feeling of lack of energy especially noticeable; inability to complete any work; want of pleasure in life; thoughts of suicide; avoidance of people; moodiness; inclination to hypochondria; spinal irritation and headache following masturbatic excesses. There was an unconquerable fear of hetero-sexual intercourse; last coitus performed nine years before without functional disturbance, but with embarrassment.

Patient of delicate constitution, well nourished, of medium size. Thorax well developed. Right supra-clavicular groove somewhat sunken. Percussion and auscultation afford no indication of existent lung disease. Heart-sounds pure; cardiac dullness normal. Genitals of medium size; phimosis. The prepuce cannot be completely retracted without pain, and this is an obstacle to the performance of the sexual function.

Appetite, digestion, and sleep good; but rising early in the morning requires much resolution. Wakes frequently with erections, which lead to onanism. Masturbation twice during the last week.

The patient has great faith in hypnotic treatment, and wishes to have his desire for work and his sexual function restored by suggestive treatment.

From November 3, 1890, he is treated daily. He passes into the second stage, hypotaxis and suggestive catalepsy. Gradual deepening of hypnosis. The patient remains in the hypnotic state about half an hour, and passes gradually into natural sleep. Suggestive removal of the symptoms and the inclination to onanism. Repetition of the influence upon the feeling and the desire to work.

November 14th, operation for phimosis; wound healed at the end of the month.

In spite of the removal of the obstacle, there is still a certain reluctance to perform coitus. Still, gradually, through suggestive treatment, it became possible to induce the patient to make several successful attempts (during the first part of December). Besides, the patient, from the first day of treatment, began to employ himself in mental work with exact regulation of hours. Gradually the sense of pleasure in

work came as a result of the suggestions. The onanistic tendencies were at first successfully fought against, and then they became less frequent. The gloomy thoughts disappeared.

December 18th the patient departed, and, as the most important result of thirty-eight hypnotic sittings, there was an essential inward change in the patient. He masturbated no more, and began to take pleasure in hetero-sexual intercourse. He took up a regulated occupation without injurious influence on his nervous system. The depression disappeared, and there were no more physical complaints. On December 15th rheumatism of the right shoulder was overcome in two hypnotic sittings. N. also believed that he had gained in resistive power, for he was able to endure quietly a very painful misfortune; in his opinion, the same misfortune previously would have been the source of violent emotional excitement.

The patient went home delighted with his unmistakable improvement. After his return, on January 27th, at his desire, the treatment was resumed to change his improvement into an actual cure. Though the sexual act is successful, still the patient has no desire for it; and the satisfaction it gives, notwithstanding complete erection and ejaculation at the proper time, is not like that afforded by onanistic manipulations,—an observation which has been made by experienced physicians in women.[1]

Up to March 9th the patient was subjected to thirty-two more hypnotic sittings, with the most favorable result on his general condition. During this last period he performed coitus twice weekly, as a rule. He was no longer troubled with onanistic inclinations. Finally, satisfaction in the sexual act and libido sexualis came up to the patient's desire. In spite of my advice to be careful, he gave himself up to the pleasures of the carnival, and during the month of February had headache removed by suggestion three times. The headache was referable to carousing all night.

March 9th I made the following entry in my journal: "Ideas opposed to coitus have entirely disappeared. Libido and satisfaction perfect. Embarrassment, shyness, and melancholic tendencies no longer present. Desire for work and pleasure in life have returned. Onanism overcome; spinal irritation removed. Migraine occurs only after especial excesses. The nervous system is strengthened, has resistive power, and the patient is now fully able to follow his occupation and conclude a marriage which he desires."

He is to be regarded as *completely cured* of his onanism; on the other hand, with reference to his neurasthenia, considering his hereditary neuropathic disposition, I can regard him only as *relatively cured.*

The patient returned home March 9th.

[1] Comp. Dr. Lahmann, "Ueber Onanismus beim Weibe als einer besonderen Form von verkehrter Richtung des Geschlechtstriebes," Therapeut. Monatshefte, April, 1890.

Although, in the foregoing case, hypnosis was repeated seventy times, there were never any injurious effects observed: no loss of resistance to external influence, no spontaneous hypnosis, no breaking up of the personality (Benedikt); on the contrary, the patient, who had been shy, languid, devoid of energy, and without pleasure in work, became a happy, industrious man, energetic, and with normal sexual functions, which gave him physical and mental equilibrium and made him capable of resuming his place in life.

In this case suggestive therapy did all that was possible. Whether the patient's congenital condition,—the neuropathic disposition,—which in itself is unalterable, and the tendency to pulmonary disease will again lead to a renewal of symptoms remains to be seen. Thus far, we can only say that, according to the patient's reports, up to the present time he follows his occupation industriously.

Case 15. *Personal Observation. Successful Suggestive Removal of Imperative Sensations Due to Onanism.*—G., male, aged 26. Paternal grandfather drinker; maternal grandparents died of tuberculosis. Mother neurasthenic, timid, easily excited. Father, brother, and sister healthy. Father's relatives subject to heart disease. In childhood patient had measles and pleuritis, and later several attacks of fever (malaria?). G. is robust and strong, and weighs 200 pounds. Greatly developed panniculus adiposus. Heart and lungs without demonstrable disease. G. presents an hereditary neuropathic constitution. According to his autobiography, as a child he was easily excited and remarkably irritable, and was eccentric. From his twelfth to his fourteenth year he masturbated several times daily, without noticeable unfavorable effect on his physical health. On the other hand, the onanistic excesses seem to have been the exciting cause of development of psycho-neurasthenic symptoms; for since that time the patient's memory had grown remarkably weak, and he had lost energy. As a child shy and retiring, he now kept more and more to himself, and his timidity often became the object of joke by his companions. A book on "self-protection" explained to him the injurious effects of onanism, and he abandoned the vice. G. gives the impression of an apathetic, weak-willed man, devoid of self-confidence. Without advice, he gave himself to the study of medicine. In spite of his fourteen semesters, he is still a diligent student. Two years and a half ago, after nine semesters, he passed the *physicum*. He is constantly troubled with the knowledge of having been left behind by his com-

panions, and avoids, as far as possible, his former comrades, who have become practicing physicians. He has also abandoned his best friends. He likes best to take long, solitary walks, and, without thinking more deeply of his fate, lives, as he expresses himself, "*Tag für Tag ins Blaue hinein.*"

He has no desire for sexual intercourse, but from time to time he performs coitus normally, in order to prevent pollutions, which otherwise are frequent (three weekly). He is potent or impotent according to the mental condition at the moment. Physically, the patient complains that on the slightest excitement he has cardiac palpitation and outbreaks of perspiration. At school he was timid and blushed whenever his name was called. These imperative states of anxiety are at present prominent in his trouble. When he is called upon by one of his clinical teachers to examine a case, this feeling of anxiety overcomes him, so that he feels paralyzed and wholly unable to answer or even to leave the auditorium. Owing to this, the patient has not been able to obtain the eight certificates of practice necessary to allow him to take the State examination. He has put off this duty from semester to semester. At the present time (June) he has the alternative of losing a year or of overcoming the impediment during the last month (July) of the semester.

This painful position, which makes G. incapable of doing anything and brings his future in question, induced him to consult me on June 22d.

June 25th, first hypnotic attempt (method of Bernheim-Liébeault). G. passes into the second stage,—*i.e.*, in spite of retained consciousness, he is unable to resist the suggestions. Suggestions: (*a*) After waking, you will ask me for a cigarette. (*b*) You must obey unconditionally the next call to "practice," like an automaton, and will be unable to keep your seat.

After waking, the patient declared that he had not slept, but that, only to please me, he had kept the position suggested. He thought this first attempt had been entirely unsuccessful, in accordance with his preconceived notion of hypnosis and the actual. Apparently, he took me for a credulous person, and left without performing the post-hypnotic suggestion. As the later statements of G. revealed, after leaving me, he went to a friend about 4 o'clock. Strange to say, here the thought of a cigarette came and did not leave him. Unwilling and annoyed, he left his friend's house at 5 o'clock to find himself, a little later, in the park in front of my dwelling. For an hour he struggled, walking in the park, against the impulse to regain his equilibrium by visiting me. At 6 o'clock he called, but did not find me in. The next morning, at 10 o'clock, the patient entered with the words, "A cigarette, please; and I promise to really 'practice' from this time forward." The self-deception of many patients concerning the events of hypnosis, to which, also,

Bernheim and Forel have repeatedly called attention, could not be more clearly illustrated than by this experience with a person who, owing to his medical education, was the more entitled to express an opinion.

As early as June 26th the patient was able to master his imperative feelings,—*i.e.*, to practice.

G. was thereafter hypnotized five times: on June 26th, 27th, and 30th, and July 2d and 11th.

Relapse between the 4th and 11th of July. Inability to respond to his name in the gynæcological clinic. After energetic suggestion on July 11th, the patient went voluntarily to the assistants at the clinic, and a few days after this hypnosis he obtained the needed certificate.

August 1st G. informed me, with delight, that he had all eight certificates necessary to allow the State examination. He was of the opinion that he never could have obtained them with his own efforts without the suggestive stimulation.

The psychical after-effect of this success upon the patient's self-consciousness was unexpectedly favorable. His mood was lightened and hope raised. Although, from the stand-point of the physician, the patient was by no means to be regarded as cured, still, I had to follow the wishes of the patient, who, relying upon his own powers, thought he could dispense with further suggestive treatment, and desired to attempt his own cure.

I regard this case, so instructive for suggestive therapy, as worthy of report, because, between the onanistic excesses and the development of the psycho-neurasthenic symptoms which became especially prominent on June 22d, and, though weakened, are still present to a certain extent, there seemed to be an etiological relation.

Case 16. *Personal Observation. Masturbatic Inclinations and Neurasthenic Symptoms. Successful Treatment by Suggestion.*—A., male, aged 19 years. Mother nervous. Father and other members of family healthy. No severe illness aside from diseases of childhood. He masturbated from his fourteenth year with the idea of coitus, at first daily, later once or twice a week.

A. finds that his mental strength suffers. He grows weak-willed and has no more power of endurance. Easily tired mentally. Inability to carry on his studies regularly. Great confusion. He has seldom performed coitus and has a remarkable shyness about intercourse. He is treated in twelve hypnotic sittings; passes into hypotaxis at the first attempt. He relapsed but once during the course of treatment. The masturbatic inclinations disappeared, and he performed coitus once a week. His ability to work returned. Subjective feeling of well-being returned, and at the present time complaints of neurasthenic symptoms have ceased. He is still under observation, but he may already be regarded as essentially improved.

Onanism through Psychical Stimuli.

(Cases 17 and 18.)

Case 17. *Observation by Dr. Wetterstrand. Psychical Onanism Essentially Improved by Suggestive Treatment.*—X. X., medical student, aged 26 years. While during a year he was engaged to be married he noticed that sometimes lascivious thoughts came to him. He fought against them strenuously, but without success. His fancy was filled with frivolous images, and, at the sight of his *fiancée* and other ladies of attractive appearance, he experienced irritation and tickling on his penis, which were accompanied by erection, often ending with ejaculation. He suffered with this inability to control his imagination, and therefore consulted me on October 22, 1889. He was hypnotized five times, and, although the time was so short, he was still considerably improved.

On December 14th the patient wrote: "I feel that my trouble has been considerably ameliorated, and therefore I would once more express to you my warmest thanks."

Case 18. *Personal Observation. Psychical Onanism (due to Masturbation Practiced during Eight Years), with Hysterical Symptoms and Beginning Apathy, Cured by Suggestion.*—A., female, aged 20. Mother nervous. Father died three years ago with apoplexy. Grandfather healthy. A. has had no especial diseases. She has menstruated since her fourteenth year, and has masturbated about as long. She seems to have had pruritus vulvæ, which the sexual irritation followed. Uncertain on her legs for years. The emotional shock caused by the death of her father, three years ago, was very severe in its effects on her. She became nervous, often aphonic; complained much of headache and pain in the abdomen; restless sleep, loss of appetite, dizziness. A. became more quiet and apathetic, and took less interest in everything. She was treated by the family physician with medicines and electricity without result. Repeated attempts to hypnotize her were unsuccessful. She then came to X., and was treated by Dr. P., to whom I am indebted for these facts. To the complaints mentioned were added vomiting, diarrhœa, anæmia. At the same time there was great desire for medicines (phenacetin, antipyrin, and bromides). It was difficult to keep her from using these medicines. The hysterical attacks recurred again and again; in September, 1890, quite severe hysterical attacks, with weeping, crying out, confusion, but with retained consciousness. At that time Dr. P. had but a suspicion of masturbation. Spots of blood on the linen that had been partially rubbed out and a careful questioning induced the patient to confess.

During this period she masturbated very frequently; at least, several times a day she rubbed the vulva and clitoris, and at night she always had a finger in the vulva or vagina. Irritation and itching became

especially intense immediately before and after menstruation. The whole vulva was greatly swollen and there was fluor albus. Applications of carbolic acid, cocaine, and glycerin with chloroform, were without effect. Faradization of the vulva was temporarily beneficial, and it was used twice daily until she was sent to Munich. Owing to her great lack of voluntary control, she was placed under the constant care of a nurse, and day and night her arms and legs were secured. For sleep she was given sulphonal gr. xxx and paraldehyde ʒiss, alternately. The tendency to masturbate continued strong. Whenever it was possible she made shoving, rubbing movements with the legs, the pelvis (on the edge of the chair), masturbated through her clothing (hand in pocket) while out walking, and used every opportunity in the bath, etc. One night she succeeded in releasing herself, and in the morning she was again found with her finger in her vagina. During the last six or seven weeks of her stay in X., she did not directly touch the vulva with the finger or hand, and she also tried to give up the movement on chairs. She walked out often and slept without medicine; but she was often restrained during the day, and always at night.

In May, 1891, Dr. P. made three attempts to hypnotize the patient; at the third she went to sleep, but suggestion was unsuccessful. Further attempts were not made. Weight, when received, 90 pounds; January, 1891, 100 pounds; September, 1891, 92 pounds. Even though there had been unmistakable improvement, Dr. P. thought that hypnotic treatment might lead to complete recovery, and sent the patient to me in Munich in the middle of September.

After personal examination on September 17th and 18th, I was able to extend Dr. P.'s observations and statements, as follows: Heart and lungs apparently healthy. The patient appears as about 16 years old. Sensation to painful impressions increased on the flexor surface of extremities; reduced on the extensor surface, and in part absent. The tactile sense at some points, especially on the extensor surface of the upper arm, is diminished. No disturbance of temperature sense, localization, or muscular sense. Uterus and ovaries sensitive to pressure; intense hyperæsthesia of the vulva. Bilateral peripheral narrowing of the visual field. Color sense normal; likewise acuity of vision and hearing, but easily fatigued. Smell and taste normal. There is constant headache, pain in the abdomen, and unbearable itching of the genitals. Weight, 93 pounds. Hæmoglobin, 75 per cent. (estimated with Gowers's hæmoglobinometer).

Patient seems depressed mentally. Complete weakness of memory; so that the patient, for example, cannot recapitulate the words and meaning of a short written extract. Want of energy and dull apathy for all external impressions. She performs automatically what she is told to do. She has no interest whatever in employment or pleasures

(theatres, concerts). Lack of all spontaneity. She asks no questions and opposes all efforts to rouse her from her indolence. Occasional transformation of this state to exaltation, loud hysterical laughing, and cramp-like convulsions.

Observation for several days and careful examination of the patient show that the present form of gratification is psychical onanism. The idea of a male person,—one of her relatives,—as well as his caresses, induce sexual orgasm, without mechanical help of movement of the limbs, which is manifested in slight convulsive jerking. The patient knows nothing of sexual intercourse, conception, etc., and therefore her imagination is never filled with lascivious images and scenes; but, in remarkable contrast with her libido sexualis, it has remained pure, like that of a child. Pleasant or intense lustful sense-impressions of various kinds are capable of inducing orgasm; thus, for example, scenes at the theatre, musical impressions, or the sight of beautiful pictures, which need contain no figures (human), like beautiful landscapes, suffice. Likewise, simple bodily contact (hand-pressure) with attractive persons induces lustful trembling. The patient masturbated near me three times in the horse-cars, and that without any noticeable movement. At the same time, like many hysterical persons, she was not without great cunning, and only after close questioning did she confess the truth with reference to the number of her sexual attacks.

September 18, 1891, first hypnotic experiment (Liébeault-Bernheim method). Hypotaxis, suggestive cataleptic phenomena, with inability to resist the suggestions. No post-hypnotic amnesia. Owing to the marked apathy, the patient comprehends the suggestions with difficulty; the ideational stimuli must be made very energetically, and often repeated, in order to make them effectual. From this time she received the following suggestions daily: (*a*) abhorrence of every kind of onanism; (*b*) purity of thoughts; (*c*) cessation of headache, abdominal pain, and itching; interest in external affairs.

After going into the hypnotic state, the patient daily continues in hypnosis from a half-hour to an hour and a half. Besides, with the consent of her mother, the sexual relations and the dangers of self-abuse are rationally explained to her.

Patient states that she does not dream; at least, she has no memory of dreaming; but her restless sleep and violent headache on awakening daily, as well as the depression associated with it, give rise to the presumption that, even with restrained arms and legs, the psychical onanism is continued in dreams.

According to my notes, with daily continuance of the hypnotic treatment, the decrease in the frequency of the onanistic attacks was as follows:—

Auto-sexual satisfaction by means of idea: September 21st (for the

last twenty-four hours), 6 attacks (1 by means of friction); September 22d, 3 attacks; September 23d, 2 attacks; September 24th, 1 attack; September 25th, 2 attacks; September 27th, 4 attacks; September 29th and 30th, none; October 1st, 2 attacks (from looking at paintings); October 2d, none; October 3d, none, and none on the days following.

During October there was unmistakable improvement. She stated that she avoided all ideas that could have induced attacks, and relapse was infrequent. This improvement was recognizable objectively in the patient's general condition. She became more lively; asked questions of those about her and of the physician; employed herself in reading, reading aloud, and letter-writing, and her mood and mind became brighter and more active.

Relatively, the most favorable time in the patient's condition was always immediately after hypnosis; in contrast with her restless sleep at night, she slept in perfect quiet. During these post-hypnotic periods, which at first lasted an hour, then four hours, and finally the remainder of the day, the stimulus to masturbate and the itching were absent, pain ceased, and her mood was pleasant. Thus, suggestive treatment showed itself to be the most effectual of all curative means, and always gave the patient great relief. To overcome the hyperæsthesia of the genitals and the pruritus vulvæ, daily sitz-baths gradually cooled, frequent use of vaginal tampons, application of cocaine solution, ointments with calomel, frequent cold bathing, etc. Besides, on retiring, bromides and sulphonal were given to induce quiet sleep, and to have an anaphrodisiac effect. The application of the galvanic current was also finally used to combat the headache and the feeling of pressure in the occipital region (especially mornings after waking). Further, in order to stimulate her mind and divert her attention from her favorite dreams, the patient was taught in several studies. Gymnastic exercises, within the customary limits for young girls, completed the general treatment.

The patient is still treated in this manner, and her improvement is to be attributed in greater part to the forty-two hypnotic sittings. She grows brighter mentally; sleep grows quieter; pain becomes less frequent and intense; the post-hypnotic remissions grow longer; the hyperæsthesia of the vulva is essentially diminished. The stimulus to masturbate and the itching occur less frequently, and they are weaker. Of late there are no more onanistic relapses, though the patient is still restrained at night as a precaution. Gradually the patient has developed an intense repugnance for onanism, so that finally every question on the subject is answered with irritation and repugnance for the vice. The progress is slow, but constant, and she may already be regarded as essentially improved. Present weight, 98 pounds; hæmoglobin, 80 per cent.

From September, 1891, to April, 1892, the patient was treated with about one hundred and fifty-two hypnotic sittings, and during the last

four months she regularly passed into deep somnambulism. Since this time she has masturbated no more, and may be regarded as essentially cured. For a month there has been endometritis, which has yielded to local treatment. Headache and abdominal pain have disappeared entirely, as well as the troublesome itching. From a languid, apathetic patient, she has become a bright young girl of gay mood, with a fresh, blooming appearance, and full of interest in all that takes place around her. She will be sent home in a few days as cured.

Satyriasis and Nymphomania.

(Cases 19 and 20.)

Case 19. *Professor Forel, Zurich. Satyriasis, with Weakness of Will and Inability to Work, Lastingly Cured by Hypnotic Suggestion.*—Mr. X., student, aged 25, came to me in July, 1889, for consultation. Since 1885 he had committed sexual excesses, either with women or in onanism. The impulse became irresistible two or three days after the last indulgence; he was forced to masturbate. Mentally affected by it (probably by the mental impression, through auto-suggestion, rather than by the number of emissions); since the summer of 1888 he had become so languid and weak of will that he was absolutely incapable of work. He remained in his room, listless and abulic, and did nothing, totally neglecting his studies, and he could not continue his work for the doctorate.

In this condition, which had existed for a year, he came to me, told all, and asked for help. In July, 1889, I hypnotized him, and brought about hypotaxis (without amnesia). Ability to work returned immediately; the spell was broken. Mr. X. was hypnotized six or eight times in all. There was likewise great improvement as regarded onanism; at first it gradually diminished. Now and then it was still practiced, and for the last time in February, 1890. However, the sexual instinct lost, as a result of suggestion, its violent, impulsive character, and soon became perfectly normal,—*i.e.*, aside from infrequent coitus, at the most, there was but one pollution a week. Since the first hypnotic sittings (July, 1889) his ability to work has continued undisturbed and unlimited up to the present time (July, 1890). He was not hypnotized thereafter. Mr. X. was always nervous, but otherwise of genial temperament and normal.

Case 20. *Personal Observation. Nymphomania with Hystero-Masturbatic Attacks. Cured by Suggestion.*—M., aged 22, teacher. Father died of spinal disease. Mother healthy. Two cousins insane. Brothers and sisters healthy. The eldest sister is said to be remarkably apathetic. M. was healthy in her early youth. When she was about 5 years old and living in a large city, for a long time an officer was accustomed daily to take her up from play with her companions immediately after closing

his office. He took the innocent child to his room, caressed her, touched her genitals, and, after having covered her eyes and mouth, he committed immoral acts with her,—masturbated her, undressed her, and became intensely excited sexually, probably with orgasm. The pleasant feelings which he caused the child by his manipulations, on the one hand, and threats to kill her if she were to tell on him, on the other, caused M. to keep silent concerning the matter. In this way, during the two years of continued intercourse, the childish imagination was thoroughly poisoned. After the relation ceased, the child began to practice auto-masturbation excessively. At the age of 11 the menses began. At the age of 17 she went to France as a teacher, and at 18 she was deflowered, and, up to the present time, states that she has had coitus about ten times. A relative accompanied her to my office, and I noted the nervous excitement of the former. A short examination showed that her companion was more seriously affected than M.

During the last ten years the onanistic manipulations have been practiced from eight to twelve times daily, and have seriously affected M.'s predisposed nervous system. She states that she has never touched her genitals with her hands, but she induces the orgasm by movements of the thighs; its occurrence is often accompanied by hysterical convulsions and loss of consciousness. The patient feels much fatigued after these onanistic attacks. The ideas accompanying such attacks often consist of the thought of having intercourse with some man. The intensity of such thoughts often reaches that of hallucination. The severest attacks occur in the morning, while the patient is lying on her abdomen in bed. She states that at such times the impulse is irresistible. She is absolutely unable voluntarily to control the impulse, and thus she has become the slave of the psycho-sexual reflex mechanism, which is thrown into action by all kinds of sensory impressions and ideas. For some years orgasm has taken place without tactile stimulation of the genitals at the occurrence of certain perceptions, accompanied by intense pleasurable feeling (psychical onanism); thus, for example, when the patient sits dreaming on the sea-shore watching the play of the waves; while lost in contemplation of the river Isar; while looking at certain paintings containing nude figures, or even at landscapes devoid of figures; at the sight of attractive male forms; or even at the mere contact with a man (pressure of hand). These ideas in the form of memory-pictures are also sufficient, without mechanical friction, to induce the sexual orgasm.

In general, all sensory impressions and ideas which induce pleasurable sensations are capable of bringing about lustful feelings. The patient's dreams are also effectual in the same way. She states that a short time ago she dreamed that she was in the arms of the emperor. Her whole thought is directed to the sexual sphere. Her impulsive

excitement reaches the intensity of nymphomania, with an inclination to attack men. She fears her own passion, and begs me never to leave her alone with a man in the waiting-room. In such states of excitement it is only with the greatest difficulty that she controls herself. Increased cardiac action, rapid breathing, and suffusion of the face are the objective signs of her exaltation. Repeated onanism during the first visits to the physician, as well as during the physical examination.

Her mental condition has seriously suffered under the constant influence of this sexual hyperæsthesia that has existed for years. Weakness of memory, absent-mindedness, inability to follow out a thought, hysterical change of mood, etc., make it impossible for her at present to follow any employment. Nevertheless, with due consideration of her hysterical state of mind, she does not impress one as being a person degraded or morally defective. She feels that she is ill, and has an earnest desire to get well, but that she cannot attain this by means of her own strength. She has by no means lost her sense of modesty, and, in spite of her violent sexual impulses, she has not prostituted herself. The dramatic dream-life of the patient, as fully revealed later during hypnosis, gave the observer a view of the patient's secret mental life and many opportunities for interesting psychological studies. These experiences confirmed the judgment made of her character in the waking state.

M.'s form is stately; full bust. Panniculus adiposus well developed. Mucous membrane ruddy. Heart and lungs normal. On the posterior surface of the right forearm there is an area of anæsthesia, pear-shaped, fifteen centimetres long and seven centimetres wide. In the right axillary line, at the level of the fourth rib, there is a point sensitive to pressure; right ovary also sensitive to pressure. Genitals normal, not especially sensitive; moderate turgor of the clitoris, which is remarkably large. Occasional pruritus vulvæ. Color-blind for blue and red. The right visual field concentrically narrowed. Olfactory and gustatory anæsthesia on the right side. Quinine and salt are not tasted on the right side of the tongue; asafœtida, violet perfume, and smelling-salts are not smelled on the right side. On the other hand, on the left side, these substances induce lively reaction, with correct recognition of them. No olfactory hallucinations. Hearing intact on both sides.

The menses increase the hyperæsthesia, last four days, and cause pain and weariness in the legs. Repeated vesicular spasm with active retention of urine (attributable to reflex irritation after onanistic excesses) on attempting to urinate. As a rule, the spasm ceases after five minutes.

September 25th I attempted to hypnotize her for the first time, but without success. With face suffused and excited, she threw herself about in her chair, and the attempt ended with an hystero-onanistic

attack. I then had her come every day, and showed other hypnotized patients, and suggested to her in the waking state that she was not to become excited when visiting the physician. Thereafter she became much quieter, and I could touch her without causing her sexual excitement. She then asked to be hypnotized.

September 30th, second hypnotic attempt (Liébeault-Bernheim method). In less than a minute M. goes to sleep and passes into deep somnambulism, with post-hypnotic amnesia. She carries out all suggestions, hallucinations, acts, and commands in the domain of the body with perfect precision. She is one of the best somnambulists I have ever seen (*sonambule agitée*). As a rule, if no contra-suggestion is given, she acts out her dreams, speaks of the events of her daily life, and takes up, from time to time, an imaginary glass from the table to strengthen herself, and has hallucinations of all possible situations. After I have suggested to her abhorrence for onanism, she always says to herself the following sentences: "Ugh! that is bad; you must not be naughty; the doctor does not allow you to be; I abhor it." In the following sittings, auto-suggestive recapitulation of the suggestive commands of previous sittings. She twice struggles successfully against the impulse to onanism in hypnotic dreams. Once, in a dream, she allows the imaginary glass to fall to the floor; she begs pardon, and wishes to take up the pieces. When it is suggested to her that a lead-pencil is a red-hot iron with which she is to be burned on the arm, the touch is followed by violent painful reaction, manifested by jerking the arm away and crying out. Sometimes the places touched on the arm clearly showed a red line (the first degree of burning); at other times there was nothing apparent. On one occasion desquamation of the superficial layer of the skin, with formation of crusts for some days; but it is not certain whether or not this process was hastened or brought about by scratching or rubbing at times when she was not under observation. In one instance she blew on the spot that appeared burned (not yet erythematous), and poured the contents of this imaginary glass over it, in her imagination thus overcoming the irritation,—all this without the skin reacting with redness.

Every one of the stigmatic experiments tried by me on this patient underwent correction when I ascertained that in the waking, as well as in the sleeping, state every moderately-intense tactile impression induced circumscribed hyperæmia of the skin, whether there was any suggestion at the same time or not. With moderate pressure with a piece of wood (lead-pencil) one can draw on the skin of the arm, breast, etc., any kind of a figure, which, in half a minute, appears as an erythema traumaticum in the form of the figure drawn. In this way the word "Otto" appeared in red letters on the left breast; likewise the number "1" which I had written on her arm over the sleeve. Still, the possi-

bility that this may be induced by the ideational stimulus is not thus denied.

We see other vasomotor changes brought about by psychical stimulus as well as by tactile irritation: for example, erection. Careful exclusion of mechanical irritation is necessary to establish the occurrence of erythema as a result of suggestion. Though some of the suggestive experiments made in the vasomotor domain seem to have excluded mechanical irritation, still, I must confess that I have not yet reached a final judgment. This class of experiments is not continued with the patient.

The importance and the infrequency of the phenomenon in question, which forms a part of the patient's history, constitute my excuse for this digression.

October 2d and 3d, repetition of suggestions against onanistic inclinations. October 2d, M. masturbated while looking at a picture (Tannhäuser in the Mountain of Venus), though since the first sitting the attacks had decreased in frequency. October 3d it was suggested to her: You will have a severe pain in the region of the left ovary every time you attempt to masturbate, and will be able to overcome the impulse. The following three days there was not a single attempt to masturbate, though the patient remained in bed until 10 A.M. When, on October 4th, she made an attempt to masturbate, there was violent pain in the left ovary.

From October 8th to 15th, daily repetition of the therapeutic suggestions; successful suggestive removal of the anæsthesia of the right arm; no more onanistic attacks. October 16th, relapse, with violent ovarian pain. From October 16th to 31st, further hypnotic sittings without relapse. The general health improves; nymphomaniacal inclinations have been absent since the beginning of October.

At the present time the patient may be regarded as capable of following her employment, and has begun to resume it. Her sexual hyperæsthesia is much diminished; her general physical and mental state is essentially improved; the inclination to onanism has decreased. The patient is still treated intermittently.

At this period it may be stated with exact certainty that the improvement, in the sense of a relative cure, is to be ascribed to hypnotic treatment.

December 15th. The patient is to be regarded as completely cured of nymphomania. She does not practice onanism any more, but at the time of the menses she is excitable sexually, and, to avoid a relapse, at these times it is necessary to treat her prophylactically.

March 10, 1892. The cure of the onanism in about forty hypnotic sittings is complete. No relapse anticipated. The patient is still under treatment.

Concluding Remarks.

The foregoing table gives the following results:—

Cured, with subsequent report, (2 still treated prophylactically; 1 case with relapse.)	10	13 =	65 per cent.
Cured, without subsequent report,	3		
Greatly improved, (3 with subsequent report; 1 case still under treatment; 1 case relapsed.)		5 =	25 per cent.
Temporary improvement,		1 =	5 per cent.
Complete failure,		1 =	5 per cent.
		20	100 per cent.

Of the 20 cases of onanism (among which the cases of satyriasis and nymphomania are reckoned), 11 passed into somnambulism, 6 into hypotaxis, and in 3 cases no degree of hypnosis is given. The number of hypnotic sittings extends from 3 to 152. Of the 20 cases, 10 were completely cured, with subsequent reports; 3 without later reports,—in all, 13 cures. In addition, 3 were lastingly improved, with subsequent reports. According to this, the probability of lasting cure of onanism or sexual hyperæsthesia by hypnotic suggestion may be expressed as 65 per cent.; the probability of some success, as 90 per cent.

For the sake of a *résumé*, the two cases of satyriasis and nymphomania in which onanism plays an important part were included.

The great susceptibility of onanists to hypnosis seems remarkable, of whom eleven passed into somnambulism. This is in part due to the youth of the patients. But even the milder degree of hypnosis does not prejudice the result, as Case 14 shows. In spite of the seventy sittings, the patient did not go beyond the second stage; yet the therapeutic effect is among the best obtained.

Owing to the great excitability of hysterical and neurasthenic persons. the first attempt to hypnotize them is not always successful. In Case 20 the patient could not be hypnotized on

the first trial, owing to an intense degree of psychical erethism. Only after she had seen several hypnotized patients did she have a desire to be hypnotized. I artfully increased this desire by having her come several times and making her wait for a long time, so that her requests became more urgent. I thus induced a favorable psychical predisposition, and at the second attempt she passed immediately into somnambulism.

In Case 18 several physicians had previously made attempts to induce hypnosis, but without success, because she laughed at them. Slight hypotaxis at the first trial. I regularly allowed the patient to lie asleep for half an hour, as a result of which the hypnosis gradually deepened, so that later deep somnambulism always occurred. Owing to the apathy which excessive onanists show for all impressions, suggestibility is much diminished, and Case 18 shows that the depth of hypnosis, in spite of the existing *rapport*, does not always correspond with the degree of suggestibility.

The more the patients are accustomed to masturbate automatically, as in sleep, the more difficult it is to affect them. In such cases we cannot dispense entirely with other therapeutic measures. Appropriate bandages, belts to prevent masturbation, etc., are of the greatest service in such cases. Bérillon has also lately advocated this view, he having successfully treated about thirty cases of confirmed onanism by suggestion.[1] It is also well, where the patients present erethism, to prepare them for hypnosis by large doses of bromides. At least, I was repeatedly successful in deepening the hypnosis by this means. In addition, general treatment of the nervous system—for example, by hydro-therapeutic procedures—should not be spared.

Case 15 demonstrates beautifully that suggestion may force its way into the patient's mind in a state of complete con-

[1] Comp. Revue de l'hypnotisme, Dec., 1891, p. 180. In the reported discussion of a paper by Professor Bernheim, Dumontpallier and Gorodichze report cures of severe cases of onanism by means of psycho-therapeutic treatment. Since the article mentioned appeared after the conclusion of this work, the cases could not be considered in detail. The same is true of a case mentioned by Schmidkunz in his work, "Psychologie der Suggestion" (Enke, Stuttgart, 1892, p. 398). The case is one of involuntary masturbation, which was successfully treated in four hypnotic sittings by Dr. G. The patient was able to overcome later relapses partly by means of auto-suggestion and partly by mechanical means.

sciousness, though the patient thought that he had held his arm cataleptic merely to please. It is also well, in good somnambulists, to give the suggestion that pain will occur upon the first attempt to masturbate. Case 20 gives a noteworthy proof of this.

The more the onanistic habit is the result of hereditary disposition or of an existing psychopathic condition, the more difficult the therapeutic task and the more unfavorable the prognosis. Thus, in the single case of complete failure (Case 5), the patient was an imbecile; and in Case 7, in which there was but slight temporary improvement, there was marked hereditary disposition, for the father was likewise an onanist, and there were several other symptoms of hereditary taint.

One case of melancholia masturbatoria with beginning dementia I had to refuse as inappropriate for hypnotic treatment. Onanism had been practiced more than thirty years, and there was hereditary disposition. The age of the patient (female), her absent-mindedness, and her mental decay contraindicated the use of hypnosis. Since no attempt at hypnosis was made with this patient, her case is not included in the report.

In none of the cases reported was there any injurious effect attributable to hypnosis. Of course, the cases are reported by recognized specialists in suggestive therapeutics. On the other hand, I was able to observe, in several cases, that the hours of relatively the best condition were those immediately succeeding hypnosis. These favorable intervals increased in length, in the course of treatment, from several hours to half a day, then to several days.

Without regarding hypnosis as a universal remedy for onanists, I think, from the practical experiences confirming our theoretical considerations, that we may conclude that, with reference to certainty and rapidity of effect, as well as with reference to the permanence of success, no other therapeutic method has given similar results in sexual hyperæsthesia. As little as we can dispense with other means as a supplement, the application of suggestion seems to me to be, to a certain extent,

indicated as a specific remedy, since abnormal symptoms in the domain of thought and instinct, in cases of sexual hyperæsthesia, especially in the form of onanism, may thus be corrected. If other means and methods are not successful, then failure to use suggestive therapeutics out of prejudice and ignorance must be regarded as inexcusable negligence on the part of the physician toward his patients.

II. SEXUAL IMPOTENCE AND ANÆSTHESIA.

CHAPTER IV.

PATHOLOGICAL CONSIDERATIONS.

By impotence we understand complete or partial defect of power to perform coitus in a normal way with an individual of the opposite sex.[1] This is called impotentia cœundi, in contrast with impotentia generandi, which relates to the fertility of the semen.

Physiology.—The experiments of Eckhard[2] and Goltz[3] have demonstrated the interrelationship of the cerebral cortex and the sexual organs. The impulses necessary for erection arise in the cerebrum, and pass through the crura and pons to the spinal cord. The erection-centre in the lumbar portion of the cord may be excited by cerebral (sexual ideas and perceptions), spinal (stimulation of the conducting paths in the cord), and peripheral stimuli (reflex irritation from the glans penis). Ideas and sensory impressions constitute the most frequent form of excitation. The erection-centre in the lumbar portion of the cord is likewise subject to inhibitory influences arising in the brain. In dogs, section of the cord between the dorsal and lumbar regions allows more prompt and rapid occurrence of erection. Unpleasant cerebral excitement (fear of failure in coitus) intensifies the effect of the inhibitory nerves, *i.e.*, hinders erection. The accessions of blood to the corpora cavernosa of the penis, to which erection is due, is regulated by the contraction and relaxation of the organic (involuntary) muscular fibres of the tissue: the nervi erigentes relax the muscular fibres and the spaces fill with blood. Contraction of the ischio-cavernosus muscles compresses the penis near the symphysis pubis, so that the backward flow of blood is impeded; and these muscles

[1] Comp. Caspar, *loc. cit.*, p. 3.
[2] Beiträge zur Anatomie und Physiologie, Bd. iii, iv, vii.
[3] Pflüger's Archiv, Bd. viii.

elevate the penis, and erection occurs. After ejaculation the muscles relax and the penis collapses. The distended bladder may oppose the return-flow of blood (morning erections). When there is insufficiency of the muscular apparatus, there is premature return of blood, resulting in partial relaxation of the organ.

Causes and Forms of Impotence.—Sexual power may be interfered with by the most various circumstances. The physical mechanism of the sexual act requires a normal condition in all the parts concerned in it. Congenital or acquired faults or defects of the sexual organs may cause impotence (impotentia cœundi e defectus seu deformatione[1]): for example, injuries of the brain or spinal cord. Consecutively, other serious maladies, like diabetes, anæmia, obesity, etc., may lead to it. Alteration of sexual power takes place as a result of toxic influences (alcohol, nicotine, opium, etc.).

The organic changes which, as a result of anatomical lesions of the muscular or nervous parts of the genital apparatus, or of the nervous centres and paths which control erection, become the causes of impotence, should be mentioned here merely for the sake of completeness; for our purpose, however, they are important only in that in such conditions there can be no thought of therapeutic effect by psychical means. In a wider sense, congenital anæsthesia sexualis belongs here,—absolute defect of sexual instinct, notwithstanding normal development of sexual organs.[2] According to von Krafft-Ebing, a milder form of this defect is presented in the so-called "naturæ frigidæ," who show disinclination or very slight inclination for sexual intercourse, and experience no lustful or psychical excitement in coitus. Whether such cases are amenable to psychical treatment remains to be seen; at any rate, the original condition sets the natural limits for the possibility of improvement.

What is true in the case of congenital anæsthesia also holds good in the case of acquired anæsthesia, when the latter is the result of degeneration of the nervous conducting paths

[1] Caspar, *loc. cit.*, p. 11.

[2] Comp. Psy. Sexualis, p. 31; Hammond, p. 2.

and the genito-spinal centres as a result of castration, atrophy of the testicles, or central lesions (paretic dementia). On the other hand, cases of diminished or temporary absence of libido, belonging to this class, form the transition to the forms of impotence to be discussed later.

Hereditary disposition, physical condition, and age play a predisposing part in the occurrence of impotence. The sexual power begins, on an average, in males at the age of 18; in females, in our climate, at the age of 16, sometimes a year earlier. After the age of 40 sexual power diminishes, and is extinguished in men at the age of 65, in women at the age of 50. There are exceptions to this, in accordance with individuality and constitution.

Hereditary predisposition to impotence, with respect to intercourse with the opposite sex, is found in persons of contrary sexuality. Such cases are repeatedly described under the term "Impotence,"[1] and in monographs on "Impotence" are usually considered. This class of psycho-sexual diseases, belonging to relative impotence, will, owing to their great practical importance, be given separate consideration in Section III, and therefore no further reference is made to them here.

Fürbinger[2] examined 200 cases of impotence, aged from 18 to 52, and found that 50 per cent. of all cases occurred in the fourth decade of life. All these cases were from private practice; on the other hand, out of 15,000 patients treated at Friedrichshain during the last three years, only two came for defective facultas cœundi. Among such patients young single men exceed married men in number. Officers, merchants, and physicians make up the largest contingent; theologians and teachers the smallest. The cause was, in 28 per cent., onanism; in 38 per cent., gonorrhœa; in 13 per cent., both of these factors; 10 per cent. were given to great excess in venery. In accordance with these figures, 89 per cent. of cases of impotence occurred in patients who attributed their malady to onanism,

[1] Comp. Leonpacher, "Psy. Impotenz," Friedreich's Blatter für gericht. Medizin., 1887, p. 290.

[2] "Ueber Impotentia virilis," Med. chirurg. Rundschau, 1890, p. 188.

gonorrhœa, and excesses. Only 10 per cent. showed a blameless past life. Fürbinger was also able to note variation of sexual power in the same individual, in accordance with physical and mental conditions and external circumstances. I can confirm this observation from my own experience. As a rule, impotence goes hand in hand with neurasthenia. "It may be the only symptom of neurasthenia" (Fürbinger). For this reason it is difficult to separate impotentia cœundi psychica from impotentia cœundi nervosa irritativa (sexual neurasthenia), as Caspar[1] does, even though it must be allowed that this distinction, in accordance with the predominance of symptoms of sexual neurasthenia, or purely psychical symptoms, is practically useful.

In pure functional disturbances of virility the condition of the external genitals is negative, though sensory disturbances in the glans may be discovered,—frequently hyperæsthesia. The functions which go to make up the sexual act may be disturbed singly or in various combinations:—

1. Erection may be incomplete or wanting, so that the member becomes lax ante-introitum or after immission.

2. Ejaculation may be premature, too quick (præcox), or delayed, and take place with insufficient ejection of semen.

3. Orgasm may be diminished, and it is seldom intensified.

4. Libido sexualis may be diminished or increased.

In accordance as 1, 2, 3, or 4 occurs alone or in various combinations with the others, we have various varieties. Thus, for example, we may have libido sexualis increased and power of erection simultaneously diminished; or ejaculation and orgasm may be interfered with where libido and erection are normal; or libido may be almost extinguished and, power of erection being retained to a certain extent, erection occurs from peripheral stimulation, with ejaculation which is nearly normal. Fürbinger saw cases of the latter character.

The forms of impotence may be classified in accordance with other peculiarities, as *total* and *partial*, *constant* and *temporary*, *absolute* and *relative*, *original* and *consecutive*, depending

[1] *Loc. cit.*, p. 11

upon the view of the case held. In *partial* impotence one or more of the factors just mentioned are intact. *Constant* impotence signifies defective power with woman at all times; the *temporary* form is that in which there is occasional failure of erection,—for example, as a result of intense preoccupation of the mind by urgent business or of occasional mental preoccupation. According to his contemporaries, Newton was constantly affected with the latter form. This form has also been called real *psychical impotence*, or moral or hypochondriacal impotence. It presumes increased excitability of the inhibitory centre. A thought, a doubt, concerning the successful performance of coitus is sufficient to destroy erection. Cases are not infrequent where young married men, who have had intercourse before marriage only with votaries of Venus, are impotent in the marriage-bed. The absence of approach on the part of the young wife on the one hand and the fear of exposure on the other excite the inhibitory mechanism. As has been before mentioned (Section I), intense preoccupation with abstract subjects (*e.g.*, mathematics) has a paralyzing effect on the sexual function.

Absolute impotence means that the patient is impotent alike for all women, while *relative* impotence is applied to cases where the defect is manifested only with respect to certain persons; like those young husbands who can have intercourse with a puella, but not with their wives. There are also married men who are impotent outside of marriage relations, probably as a result of the custom of intensified association of ideas. There are also men who can perform coitus under definite circumstances,—for example, with dressed women,—while they are absolutely impotent with a nude puella.

Not only mental, but also severe physical, labor and great fatigue may induce temporary impotence. Gyurkovechky[1] speaks of an occupation impotence. Thus, according to him, book-worms are weak *in sexualibus*. "With intense mental activity the thinking portions of the central nervous system are thus exercised at the expense of the sensory and motor portions and consecutively developed."

[1] *Loc. cit.*, p. 132.

Sensuality and virility, in accordance with the foregoing scheme, may stand in a certain contradiction to each other, in such cases as are most frequently observed among artists and men of learning,—painters, actors, authors, physicians, and professors. Abstinence[1] also leads to impotence (consecutive atrophy of the testes), as we have seen in the preceding section.

The original form of impotence is found, for example, in individuals affected with congenital sexual weakness, the forms of which have been previously mentioned. *Consecutive* impotence signifies the occurrence of a functional weakness of the muscular and nervous apparatus of erection, resulting from general neurasthenia or some other primary disease.

In addition to this, we may mention the form of impotence depending upon delusion, and due to groundless imagination, which should be classified as belonging to the psychoses. Hammond[2] reports a case of hypochondriacal mania, in which the patient imagined that his genitals degenerated, while in fact they were perfectly healthy.

Functional weakness of the genital reflex arc and of the

[1] The results of abstinence induced by erroneous education are clearly shown by the following communication, received during the publication of this work from the brother of the subject of Case 67: At the age of 15 years, X., while at school, made an attack on a servant-girl (aged 22). On touching her person he had an ejaculation. The strict discipline of his elder married brother restrained all sexual tendency at home. While serving his apprenticeship as a merchant, owing to enforced abstinence, he became hyperexcited sexually and made an attempt at rape; the approach of persons prevented its completion. He fled. After his return to a large city, a visit to a brothel. However, he found, as he believed, that his virility was much diminished by abstinence. A single act of coitus weakened him so that he was forced to keep his bed several days. Confession and a violent scene at home. His brother and guardian had practiced abstinence until marriage (in his twenty-fifth year) without harm, and demanded the same of him. Though the patient felt himself in the right, by energetic self-control he practiced abstinence five years. During the first nine months frequent tickling sensation in the glans. Frequent dreams at night, with pollutions, which gradually ceased. While bathing he accidentally came to masturbate (self-pollution), which he only practiced three times. He found that this weakened him still more. During the latter part of the five years sexual desire gradually disappeared entirely, and after abstinence for five years he made another trial in a brothel. He was impotent, and, in spite of several attempts, remained so up to the time of making this report, though not yet 30 years old. Accident so decreed that the strict guardian and brother should learn the fruits of his plan of education on the same day. He received, almost simultaneously, news that one brother had begun treatment for contrary sexual instinct, and that the other was impotent as a result of the abstinence he had enforced. Owing to the congenital neuropathic disposition of both these patients, their sexual education should have been most painstaking, in order to prevent functional disturbance.

[2] *Loc. cit.*

muscular and nervous apparatus in relation to it may result in lasting loss of sexual power,—a form known as *paralgtic* impotence. On the other hand, when it represents but a temporary exhaustion of nerve-cells, it is called *atonic* impotence.[1] In the latter form there is erection occasionally, but it lasts but a short time and is insufficient for coitus.

Impotence in the Female Sex.—Sexual impotence in women is far less frequently the object of the physician's treatment than that in men. The lesser intensity of the sexual impulse and the form of the genitals in the female sex, as well as natural modesty, are probably sufficient to account for this. Hammond[2] justly points out that our education and social conditions effect a development of the sexual impulse in the male sex much beyond the limits demanded by the interests of future generations; while, on the contrary, feminine education in civilized lands is entirely directed to restraining and limiting sexual desire.

As in the male sex, organic defects (absence or incomplete development of the clitoris) may cause absence or diminution of sexual desire. It must be remembered, however, that the mucous membrane of the vulva, the cervix, and the os uteri possesses sensibility similar to that of the clitoris, and that therefore the operative removal of the clitoris does not prevent lustful excitement (Hammond). Congenital defect of sexual instinct (*frigiditas organica idiopathica*), according to Hammond, also occurs, though it is exceedingly rare.

An anomalous formation of the genitals may render immissio penis impossible, and thus cause impotence, as may acquired anatomical defects (syphilitic growths, hernia of the labia majora, etc.).

The most frequent functional hinderance to cohabitation is vaginismus (hyperæsthesia of the hymen and the vulva, with involuntary spasmodic contraction of the sphincter vaginæ). Pain and spasm make the sexual intercourse of such patients a burden.

Usually, vaginismus occurs only after attempts at coitus as

[1] Caspar, *loc. cit.*, p. 75. [2] *Loc. cit.*

a result, for example, of spinal irritation or hysteria, but most frequently after masturbation.

Sexual excesses and want of correspondence in the size of the genitals also play a part in its etiology.

The most frequent form of impotence, and that which in its practical bearings has not been sufficiently recognized, is that due to defect or absence of the female orgasm, whether it be due to a want of sympathy with the husband or to the fact that the stimulus caused by the friction of the penis, with complete desire and intense sympathy, is not sufficient to bring on the acme of the sexual paroxysm in the woman. The man has already passed the acme, the penis becomes relaxed, while the woman is still in a state of strained expectation without having experienced the characteristic lustful feeling. This difficulty in the occurrence of the orgasm may be congenital, or —and this is the most frequent form—it may be due to sexual excesses and masturbation, or to local disease, as after childbirth. In such cases there is exhaustion of related central ganglion-cells, which no longer react promptly to the stimulus. Erection of the clitoris may also be involved. Finally, lustful sensation, just as in the male, even though it occur, may be weakened and remain incomplete.

The forms of impotence here described have excited a controversy among gynæcologists in the *Archiv für Gynäkologie*,[1] the *Therapeutische Monatsheften*,[2] and the *Allegemeine medicin. Centralzeitung*,[3] in that an attempt is made to regard such cases as " perversions," and, in support of this error, to account for it by assuming a deviation in the distribution of the nerves of lustful sensation like the hypothesis of some authors (Mantegazza) that in pederasts the terminal branches of the pudic nerve are distributed to the rectum and anus. Dr. Carl Laker gives the following characteristics of the peculiar sexual perversion of the female described by him:—

[1] Archiv f. Gynäkologie, Bd. xxxiv, Heft 2, 1889, p. 293. Laker, Ueber eine besondere Form von verkehrter Richtung (Perversion) des weiblichen Geschlechtstriebes.

[2] Therapeutische Monatsheften, 1890, p. 165. Dr. Gustav Leimann, Ueber Onanismus beim Weib als einer bes. Form von verkehrter Richtung des Geschlechtstriebes.

[3] Wiener med. Wochenschrift, 1889, No. 28, and Allgem. med. Centralztg., 1889, p. 37. Franz Torggler, Casuistischer Beiträge zur Perversion des weiblichen Geschlechtestriebes.

1. Normally developed and frequently increased sexual desire.

2. Normal inclination toward the opposite sex and absence of any pathological inclination toward the same sex.

3. Complete absence of sexual satisfaction in normal intercourse (never has been experienced).

4. Complete satisfaction of sexual desire in solitary and mutual onanism.

5. Consciousness of the abnormal condition and desire for a cure.

6. Absence of states of psychical degeneration.

Laker gives three cases as examples:—

Case 1. Sexual inclinations began in her twelfth year. Sexual intercourse in her fifteenth year without satisfaction. Seduced into mutual onanism by friends (several months later). She experienced complete gratification. Married at 22 years of age. Never any lustful feeling in coitus; always in onanism. This patient knew several who suffered like herself.

Case 2. Seduced to mutual onanism in her fourteenth year. Natural intercourse in her nineteenth year, without lustful pleasure. Increased libido. Bore two children. Owing to her anomaly, she cannot bring herself to marry again.

Case 3. Seduced to onanism at the age of 11 years. Abnormally increased desire. Intercourse with several men without ever being satisfied by coitus. Orgasm by means of auto-masturbation. According to Laker's experience, this form is quite frequent in women. To explain the anomaly, the author assumes the existence of an anatomical deviation in the distribution of the sensory nerve-endings. For this "typical common form" he recommends local surgical treatment, and thinks that perversion of the sexual instinct may develop from mutual onanism.

Franz Torggler confirms Laker's experience:—

Case 4. The patient was seduced to onanism in her fourteenth year, and was a slave to it until her sixteenth year. Then a platonic love-affair. After six months' acquaintance with her lover, mutual onanism with him, which gave her more pleasure when the clitoris alone was stimulated than when the vulva and vagina were manipulated. Coitus avoided for social reasons. Seduction in her eighteenth year. Frequent coitus; excessively-increased sexual desire without satisfaction in coitus; after every attempt at coitus, she masturbated in order to experience the acme of the sexual paroxysm. After the relation ended, resort to onanism

again. Then marriage to a man she loved. Again no satisfaction in coitus. She then came to place her hand on her clitoris during the conjugal act, in order to induce orgasm by manipulation.

Gustav Loimann gives three cases, of which the first is essentially like those reported. The second case is instructive in relation to explaining the anomaly, and for that reason may be repeated briefly here:—

The patient menstruated first at the age of 17; marriage at 20. Happy married life for ten years. Eight children. Complete satisfaction in coitus. Widow at 30. Intense sexual desire; no chance to marry again. *Faute des mieux*, onanism, which was injurious to her mental and physical health. On the advice of a physician, she entered into a relation with a student, aged 18, who had been entrusted to her care, without thought of consequences. The former satisfaction did not occur. She attributed this to the inexperience of her lover, and sought another and another. The desired satisfaction never came, but she developed a chronic vaginal catarrh. At commencement of treatment masturbation was practiced as inordinately as before.

In its principal features, the third case is similar to the second: at first complete satisfaction in marital intercourse; death of the husband; onanism; later, failure of orgasm in coitus.

Concerning the etiology of this misunderstood form of disease, which, according to the statements of gynæcologists, is frequent, it is noteworthy that in all the cases reported, with the exception of the first by Laker, auto-masturbation or mutual onanism preceded the defect of orgasm in coitus. Loimann's patients, as far as the sexual paroxysm was concerned, were potent for years until the beginning of habitual onanistic indulgence. Through frequent unnatural stimulation, the impressionability of the centres influencing lustful feeling in woman is greatly altered and diminished in power to respond to normal stimulation,—a fact which Loimann has correctly recognized. In every instance it is a form of genuine female impotence in which the orgasm is no longer induced by the sexual act. By manual friction the excitability of the clitoris is increased as compared with that of the vaginal mucous membrane and of the os uteri, and that without necessity to assume

unequal distribution of nerves to account for the variation of sensitiveness.

The question whether masturbation by means of objects resembling the penis in form, and which, therefore, do not stimulate the clitoris exclusively, but also those parts of the vagina which are subjected to friction in coitus, is likewise capable of inducing impotence, cannot be answered from the cases at hand. By analogy, it might be presumed that this form of stimulation could not cause impotence unless male ejaculations were to take place too quickly. Concerning Laker's first case, which seems to be an exception, it may be remarked that in woman lustful feeling is not always brought about by the first coitus, but that it occurs sometimes only after repetition of the act. In accordance with individual peculiarity, it requires a longer or shorter time before the various phases of cohabitation occur in a normal way. Loimann saw cases in which marriage led to complete satisfaction only after many months or after childbearing. I can confirm this from my own observation. At the present time I am treating a woman in pregnancy (aged 17), who, in intercourse during several months with her seducer, never had lustful feeling; and she experienced it first, after the occurrence of pregnancy, in intercourse with another man. Another patient assures me that of her various lovers only a few were able to induce in her the acme of the sexual paroxysm in coitus. It is the same with prostitutes, who very soon pass from the stage of hyperæsthesia to that of anæsthesia and relative impotence.[1]

In the cases described by Laker it is to be considered that auto-masturbation began only a few months after defloration, with which the pathogenesis of impotence had its beginning. Finally, want of satisfaction in the concrete case, which might be explained by speedy ejaculation of the man after immissio penis, is to be strictly distinguished from absolute impossibility. One of my patients was satisfied by her husband only at the beginning of married life, and after the birth of her child

[1] In that prostitution usually excludes the physiological condition of the sexual relation, namely, excitation of love,—the participation of the psycho-sexual centres favorable for normal coitus being either diminished in intensity or absolutely impossible,—it may be regarded as pathological and classified as one of the forms of impotence described.

remained relatively impotent with him, while she was fully satisfied by the stronger stimulus of coitus with another.

In many women orgasm occurs only after prolonged coitus or after repetition of it after a short pause. The psychical condition of women in all cases of impotence requires much more careful study than in the case of men. Sexual intercourse in woman, as a rule, includes a much more intense psychical participation than in a man. "A woman loves with her whole soul. To her love is life; to a man it is the joy of life." Unrequited love wounds him, but it costs a woman her life, or, at least, her happiness. At any rate, the mental tendency of woman is monogamous, while man tends to polygamy (von Krafft-Ebing[1]). Therefore the occurrence of relative impotence in women should be much more frequent than in men.

The pathological explanation of female impotence is often only an expression to cover up our want of knowledge of the marital relations. We are not able to ascertain how often the wife's disinclination to sexual intercourse and her apparent passiveness are due to the sexual weakness of the husband, who makes it impossible for the wife to complete the act, and thus, by nervous excitement, without subsequent completion of it, lays the foundation of nervous troubles. In judging female impotence, we must also take into consideration the decisive part played by the sexual functions in the mental life and development of woman. We should remember the numerous unhappy marriages brought about by our social conditions, the frequency of which, according to the statements of certain statisticians, is 75 per cent. The question of female impotence, in a broader sense, touches most intimately both private and social life. Upon the correct judgment of the physician, which, in the case of women, must be reached after the most careful psychological analysis of the sexual life, depends the happiness of the family and the therapeutic treatment. This often makes heavier demands upon the psychiatrist than upon the gynæcologist, who looks at everything through the spectacles of local anatomy. Thus may be explained the error of attempting to

[1] Psychopathia Sexualis, p. 14.

make a new class of sexual perversions out of cases of simple female impotence.

Diagnosis.—A careful local examination must first determine with what form of impotence the patient is afflicted. In the majority of cases, endoscopical examination of the urethra reveals nothing. The majority of disturbances of the sexual mechanism are thus of a functional nature, and reveal themselves, therefore, in the subjective sensations and observations of the patients. The discovery of the cause points out the method of therapeutic procedure. In making a diagnosis, attention should be given principally to constitution, manner of life, and the state of the nervous system in general. Often, signs of flaccidity and weakness of the genitals are to be observed; for example, in neurasthenia sexualis and after sexual excesses. In the forms of impotence resulting from abstinence, Gyurkovechky[1] found that the testicles were smaller than they formerly were. The mental condition of such patients requires the most study. The feeling of lustful pleasure may be altered or entirely absent without the necessity, for that reason, to call the patient directly impotent. If the fulfillment of marital duty become an unpleasant necessity, or if the sexual act with prostitutes is done with repugnance, lustful feeling is either much diminished or absent. There are persons who naturally possess but a slight degree of lustful sensibility. Individual disposition and the intensification of sexual desire by love determine the intensity of lustful feeling.

The foregoing points may be extended by reference to the diagnosis of sexual hyperæsthesia in Section I.

The *prognosis* depends upon the conditions in each individual case. Cases of impotence due to organic causes are to be treated locally, and are not amenable to psychical therapeutics. Congenital defect of the sexual mechanism permits only a doubtful prognosis. The prognosis in cases of impotence due to abstinence is unfavorable if the testicles are shrunken. In consecutive impotence the prognosis depends entirely upon the primary disease. Impotentia nervosa irritativa presents

[1] *Loc. cit.*, p. 138.

opportunity for treatment; for example, in general treatment of the nervous system and in the effort to re-adjust the want of relation between the various functions which make up the sexual act. Atonic impotence also permits complete cure, while in the paralytic form the organic changes in nerve-centres and paths which control erection make the prognosis unfavorable. In psychical impotence it should first be determined whether the central disturbance is primary or secondary. Gonorrhœa, diseases of the prostate, inflammation of the testicles, and onanism affect the mind secondarily; while impotence due to imperative ideas, absent-mindedness, etc., is primary. On the whole, in the cerebral neuroses the prognosis is favorable, if they are understood and treated with reference to their etiology. At the same time, hereditary disposition, in these cases, must also be taken into consideration; acquired psychical impotence, in the absence of symptoms of other serious disease of the nervous system, offers a fertile field for psycho-therapeutists. Relative impotence in married persons, for example, as a result of lack of acquiescence on the part of the wife, touches delicate ground, and offers prospect of success only in cases where both parties submit to systematic psychical treatment. The delusion of impotence belongs in the domain of the psychoses, and is to be judged and treated from that stand-point.

CHAPTER V.

THE RÔLE OF SUGGESTIVE THERAPEUTICS IN THE TREATMENT OF FUNCTIONAL SEXUAL WEAKNESS.

The causes and forms of impotence determine in each case the direction of therapeutic measures. The majority of sexual invalids (according to Fürbinger, 89 per cent.) attribute their malady to sexual excesses, onanism, and gonorrhœa. The principles of prophylaxis here are exactly the same as those laid down in the pathological states described in Section I (compare what has been said concerning sexual education, page 34).

Among the methods of treatment in vogue, correct hygienic measures are the most important. The most important means of cure is rest to the exhausted genitals. Coitus must not be indulged in for a period long enough to permit recovery. Sufficient sleep must be obtained, and diet tending to produce superfluous fat, which injures sexual power, must be avoided, as must stimulants. In addition, the measures described in the therapeutics of sexual hyperæsthesia are indicated.

If there are symptoms of neurasthenia universalis (cerebral or spinal), general treatment (climatic, hydro-therapeutic, gymnastic, electrical, etc.) is advisable. In case of combination of spermatorrhœa, chronic gonorrhœa, etc., the local treatment is given in so much detail in all special works on impotence that it is unnecessary to consider it further here. Concerning strict individualization in the application of balneo-hydro-therapeutical measures, consult the foregoing section and special works; also for the various methods of application of electrical currents, which, locally as well as generally, may have the happiest effect; for example, in anæsthesia of the glans, in the beginning of atrophy of the testicles.[1] Electricity in the treatment of impotence is also indispensable to the psycho-therapeutist. Here it is only necessary to refer to the medicaments that are briefly alluded to

[1] Hammond, *loc. cit.*

in Section I. A detailed treatment would lead us away from our subject and be but a repetition of what is familiar. Gyurkovechky[1] thinks that medicaments are not the means in the treatment of impotence which most frequently and surely lead to success. And Hammond compares the effect of substances of various properties in many forms of impotence with that of bread-pills. However, we must here examine one method of treatment which of late years, especially among French writers, has led to much discussion, viz., Brown-Séquard's method of treating impotence.[2]

The subcutaneous injection of the testicular juice of various animals in the impotence of males, according to the assertion of the celebrated physiologist, exerts a favorable influence upon diminished sexual power. There is said to be an effective principle in the semen that is capable of stimulating great power. Brown-Séquard attributed the loss of virility in old men to the diminished activity of the testicles. He (aged 72) injected on himself during three weeks an extract of testicular juice ten times. This painful procedure had a favorable effect upon him, troubled as he was by the weaknesses of old age. "In place of states of exhaustion came a feeling of strength like that of twenty years before. Again, he was able to stand without fatigue for hours. Muscular power, measured with a dynamometer, showed a decided increase. The stream of urine was stronger and of greater length. Defecation was essentially stronger. After four weeks the old conditions of weakness returned." Variot observed the favorable effect on the sexual functions in five men. An extract from the ovaries, it was presumed, would have a similar favorable effect in women. Though numerous objections were offered to this theory, by assuming that suggestion and peripheral irritation through pain played a part in the results (Féré and Dumontpallier), Brown-Séquard's reports fell on fertile soil. Chemists sought to isolate the active principle of sperma (Parke, Davis & Co.); it was called spermin or spermatin (Schreiner). The newspapers hailed Brown-

[1] *Loc. cit.*, p. 153.

[2] Fürbinger, "Zur Würdigung der Brown-Séquard'schen Behandlung der Impotenz," Deutsche med.-Ztg., vom. 22, Juni, 1891, p. 583.

Séquard's discovery as the giver of perpetual youth. And a year later the discoverer himself was forced to flee to England to escape from the impotent horde that assailed him.

A great and celebrated manufactory applied to Fürbinger, as he states, to obtain the testicles of all men subjected to autopsy in the hospitals of Friedrichshain, in order that they might meet the demand for spermatin. Later, Brown-Séquard recommended the use of the testicular fluid by enema as producing wonderful results. Reaction was not wanting. The better representatives of medical literature, even in France, kept silent. Against his inclination, Fürbinger at last decided to test the new method of treatment. In order to eliminate the psychical factor, Fürbinger took old men and patients from the lower classes who were not acquainted with the object of the treatment. He mixed fresh semen of healthy men with five times its amount of a solution of thymol, added a drop of potassium hydrate, boiled, and then filtered the whole. The solution was then used for injection. He treated eighteen men, aged from 24 to 72 years, and patients or old men affected with skin diseases, rheumatism, etc. In three days the injections were increased to five. In one-half the cases pain occurred at the seat of injection; once violent inflammation was induced. Four patients felt depressed. Two consumptives became greatly excited and had no sleep. "Not a single instance of sexual excitement reported or confessed." The failure of this test, according to Fürbinger, needs no comment. According to these experiments, the exciting and youth-giving power of Brown-Séquard's treatment seems to rest upon an erroneous assumption. All the effects may be directly attributed to auto-suggestion, as Fürbinger, Forel, and others assume.

Psycho-therapeutics.—For affecting the imagination of impotent men, there could hardly be a more effectual psycho-therapeutic procedure than this of a belief in the secret and youth-giving effect of an extract of the testicles. The very sexual origin of the substance awakens hopes and intensifies the patient's expectation. The entire attention is directed to the parts diseased, and intensified by the exciting and painful injec-

tions. The patient feels something taking place in him; his faith grows; the mysterious effect of the youth-giving juice excites his fancy in the most lively fashion. Let us remember that the cerebral part of the sexual act in almost all cases of impotence also suffers, if it be not the cause alone of impotence! Thus, the possibility cannot be denied that these factors may overcome the psychical functional disturbance and completely cure many cases of impotence. Other means used to conceal our psycho-therapeutic procedures in the waking state speak in favor of this explanation.

In the majority of cases of so-called psychical impotence, the object is to remove the influence of excited brain activity from the inhibitory nerves. If, for example, it is possible to demonstrate to the patient that he is capable of an erection, the first step toward recovery has been taken. The patient's self-confidence is thus strengthened in the most marked manner. Faradization of the genitals; the use of larger and larger metal sounds, that are left in place ten or fifteen minutes; suppositories of silver and tannin in the posterior urethra; clysters, etc., induce erection. All these means, like Brown-Séquard's, affect the patient's mind, and demonstrate the principles of psychical treatment in the waking state, which we have described in the treatment of sexual hyperæsthesia. Fear, distrust, superstition, hopelessness, and hypochondriacal mood often, as causes of psychical impotence, present insurmountable difficulties. Success with such patients depends entirely upon correct individualization and the acuteness of the physician. It is necessary to so influence the patient that he is not constantly pre-occupied with himself; that he takes his malady and any possible failure with indifference. Useless sexual excitement (for example, with a *fiancée*) must be absolutely avoided. Every forced act on the part of the patient paralyzes the erection-centre only the more. Rest of mind is the most essential thing for the patient. But one must be careful not to attempt to cure a real disease by argument; this would only make matters worse. The physician's task is to have a well-considered plan for the cure of the patient carried out. Cold rubbing, baths, medicines, and

local treatment must conceal the method of cure. The patient must gain the impression that the means used are helping him. Occasional abstinence is of use in this direction.

Patients that have become impotent as a result of severe mental work must give up their occupations for a time. A sojourn in the country should be recommended to such. In other cases they should be advised to perform coitus in a state of partial intoxication, in the hope that the alcohol will effect a partial paralysis of the mental activities. Regulation of sexual intercourse also plays a part. A suitable marriage is in all cases an excellent preventive of impotence.

Waking-Suggestion and Hypnotic Treatment.—The use of the cerebral functions for the purpose of cure consists of (*a*) psycho-therapeutics in the waking state, the special value of which in impotence is shown in the foregoing paragraphs; (*b*) suggestive therapeutics. The fundamental principles and differences of these two methods of treatment have been given in detail in Section I (Therapeutics), and they are as applicable here as there. Psycho-therapeutics takes account of the patient's judgment, the co-ordinating cerebral activity, and sets in motion his will, his attention, and his judgment. Suggestions, on the contrary, have the special tendency to cause the idea imparted to be transformed into an act. Then, the more cerebral activity is dissociated, the less is the activity of the controlling inhibitory apparatus of the brain, and thus the more the intensity of the ideo-motor, ideo-sensory, and ideo-sensorial reflex activity is increased; that is, suggestibility. *Per se*, it is a matter of no consequence whether sleep exists or not, even though it must be allowed that, in spite of notable exceptions, sleep in general increases the receptivity for suggestions. Waking-suggestion—that is, the unqualified acceptance and appropriation of an idea—always indicates a weakening of the associative and contrasting ideas, or extinction of intra-cerebral reflex excitability; that is, strictly speaking, it may be defined as hypnosis. The increasing degree of faith presumes a diminution of judgment and reflection. The results obtained with the help of imagination, in cases of impotence, show the

peculiar cerebral pliability of hypnosis; as suggestions in the waking state, they form the transition to hypnosis. Therefore, our series of cases of cures by suggestion in the waking state are placed by the side of those cured by hypnosis as a class belonging to the latter. The psycho-therapeutics of the waking state, as we have seen, pass without definite limitation into waking-suggestion, and the latter into hypnosis (in its narrower sense). The physiological basis of suggestive therapeutic effect in sexual weakness is the same as in sexual hyperæsthesia. In the patients of Section I there is increased activity of the sexual functions; in impotence, a diminution. Our introductory remarks in Chapter IV show that ideas have an exciting and an inhibitory influence on the sexual mechanism, especially on that of erection. The sexual functions stand in a dependent relation to the cerebral cortex. Ideas, desires, and images of sexual content cause sexual excitement, weaken the influence of the inhibitory centre, and, through the effect on the erection-centre, induce the well-known vasomotor and motor effects which give rise to the filling of the penis with blood.

From this it will be seen that the object of the treatment is to strengthen such ideas as induce sexual erethism, and that by weakening habitual associated and pathologically intense opposing ideas (cause of psychical impotence), as well as to increase their peripheral effect (influence on erection and ejaculation). As a result of the removal, the weakening, the dissociation "of the organically associated ideas maintaining the equilibrium," the suggested idea becomes all-powerful. The facilitation of the process of transformation of an idea into a feeling (libido sexualis) and movement, thus brought about, is, of course, not subject to observation.

However, in order to overcome the mastery of the inhibitory centres over the sexual mechanism that has existed for years, or, by means of ideational stimuli, to excite the weakened sexual functions to renewed activity, a few hypnotic sittings are not sufficient, as so many patients believe, but the unhindered ideational stimulus of suggestion must be repeated until, through cumulative effect, its intensity and lasting influ-

ence seem assured; until it acts automatically from the brain. An impotent patient who has been able to perform coitus once, as a result of suggestive treatment, can only be regarded as convalescent; only repeated and habitual success in sexual congress constitutes a cure. Length of treatment and prognosis must follow these principles.

Ringier[1] very justly remarks that in no form of medical treatment is the tendency to break it off so pronounced as in hypnotic treatment. The patient expects wonders, and, as a rule, is disappointed. The simplicity of the procedure does not come up to his expectations. Besides, the first symptoms of improvement often come unnoticed and unconsciously to the patient, in contrast with the more marked effect of physical and medicinal procedures. Besides, many patients at first, during hypnotic treatment, are inclined to ascribe the more frequent occurrence of sexual desire and erections to other causes. The causal relation of cure and suggestive treatment escapes the observation of the patient, and often it is only the constant association in time of improvement with the suggestive treatment which causes an actual recognition of the psycho-therapeutic effect. An occasional pause in treatment, as a rule, convinces such patients; for, as soon as they attempt to be independent, they recognize the assistance afforded them by suggestion.

On the whole, then, it is best to treat patients for chronic impotence with suggestion only when they will engage not to discontinue the treatment prematurely, for, by so doing, they increase their want of confidence in themselves, make a repetition of the procedure more difficult by auto-suggestion, and injure the reputation of psycho-therapeutics, sufficiently attacked and misunderstood without this. The great principle in the treatment of psychical or functional impotence is strict individualization with both men and women. The foregoing general principles will suffice; details will be found in the histories contained in the following chapter.

[1] Erfolge des therapeutischen Hypnotismus in der Landpraxis. Lehmann, München, 1891.

CHAPTER VI.

CASES ILLUSTRATING SUGGESTIVE TREATMENT OF SOME FORMS OF IMPOTENCE.

THE following eighteen cases include all instances known to the writer of suggestive treatment of impotence. By "functional" impotence in the following cases is meant a state of sexual weakness without demonstrable anatomical foundation, in so far as it is not exclusively and demonstrably of psychical origin.

RESULTS IN PSYCHICAL, FUNCTIONAL, RELATIVE, AND PARALYTIC IMPOTENCE.

Case 21. *Reported by Dr. Van Renterghem (Amsterdam). Psychical Impotence. Lasting Cure by Means of Larvated Waking-Suggestion.*—G. S., engineer, aged 29, married, fell from a height of five feet to the floor. Without being severely injured, he received several painful contusions, one in the region of the perineum. He was treated at home. For the first few days he suffered with trouble on defecation, which was soon overcome by appropriate treatment. Pains had disappeared two weeks after his fall, and he only complained that his genital functions were out of order. On April 3, 1891, his physician sent him to me. Present condition: Strong constitution. Apparently in robust health. No antecedents, either nervous or in the domain of the vita sexualis. He complains of impotence. Genitals perfectly normal. No disturbance of urination. The man is married, loves his wife, and has always lived with her in perfect harmony; and he has led a regular life, both before and since his marriage. He confesses that he attempted coitus two days after the accident, but that it was not successful, owing to pain,—a fact that caused him great anxiety. A second and third attempt, some time later, met with no better success. He thinks, therefore, that, as a result of the fall, some disturbance of the genitals has occurred which has caused the impotence. Patient is much depressed and suffers on account of the disturbance of his marital relations. I was successful in quieting him with the assurance that if some hindrance to ejaculation had resulted, it could be removed by repeated introduction of a sound. At the first attempt I introduced a sound with ease. I allowed the instrument to remain in the urethra one minute. Before the patient left he promised me not to have congress with his wife until I gave him permission.

April 7th. Though occupying a bed with his wife, he did not approach her last night; but erection occurred repeatedly. Introduction of sound.

April 10th. He asks for permission to attempt coitus. I refuse it. Use of sound.

April 14th. Patient does not appear.

April 17th. Patient excuses his absence on the 14th as a result of business. Introduction of sound. After this, he confesses that he disregarded my instructions and had congress with his wife. Coitus was perfectly successful. When asked why he had not told me this before, as it would have made the use of the instrument superfluous, he answered that he had postponed his confession purposely, fearing that I would be unwilling to continue the treatment, upon which all his faith rested.

It is to be noted that to bring about a permanent cure I introduced the sound but three times, and that at long intervals.

Case 22. *Reported by Dr. Van Renterghem. Psychical Impotence Treated without Success by Suggestion in One Sitting.*—B., civil engineer, aged 28, was sent to me July 8, 1889, by his physician, to have his belief in his impotence removed. The young man (one month married) seemed very nervous, was uncommunicative, and so anxious that my efforts to hypnotize him were entirely unsuccessful. He did not return.

Case 23. *Reported by Dr. Van Renterghem. Functional Impotence Treated in Thirty Hypnotic Sittings without Success.*—J. K., merchant, married, aged 42. Gonorrhœa. Growths in the urethra had been removed by galvano-cautery. He suffers with emphysema and chronic bronchial catarrh. Frequent (several times a day) attacks, which are sometimes accompanied by loss of consciousness. Remissions, which, however, never last more than two or three weeks. Besides, states of great anxiety, disturbed digestion, fluid stools, etc. Unhappy married life. Separate sleeping-apartments. While abroad he was treated for a long time for psychical impotence. His present physician (specalist in genito-urinary diseases) states that the impotence does not depend upon any demonstrable anatomical causes. K. sleeps well.

June 7, 1888. Pollution occurs from time to time, always preceded by complete erection. Still, K. does not venture to approach his wife sexually. He asks me to hypnotize him and suggest forcibly that he perform coitus. He thinks he cannot be hypnotized, because Donato was not successful in fascinating him.

Hypnotic sittings were had between June 18th and July 12th. However, he never passed into hypnosis deeper than the third degree of Bernheim's classification (ninth degree), and was little susceptible. The result was negative. The patient promised to inform me of any subsequent success.

Case 24. *Reported by Dr. Van Renterghem. Relative Impotence Cured by Hypnotic Suggestion.*—J. K., bridge engineer, aged 44; married at 26. He lost his wife after nine years of married life. Since this time he had had intimate intercourse with a single woman. Four months ago these relations were interrupted by a project of marriage. Since this time he had had, possibly from disinclination, only irregular intercourse. On the very first attempt coitus was incomplete, and did not give him the accustomed pleasure; and he thought himself subject to premature impotence. At second time erection occurred, but not ejaculation; a third time there was not even erection. This impotence was accompanied by an indescribable feeling of illness, and was followed by a host of nervous symptoms,—anxiety, sleeplessness, pain in the region of the kidneys, excitability, etc.

May 19, 1888, I began to treat K. He came to me in a state of great excitement. I was successful in quieting him in hypnosis. I suggested to him "disappearance of the nervous symptoms," and the assurance that his impotence had no tangible cause, but depended entirely upon his mental excitement.

May 20th. Patient has become much quieter since yesterday. He had a good night, and awoke without the feeling of anxiety. Before going to sleep he had a complete erection, and also on awaking. Repetition of the suggestions of yesterday.

May 21st. More excited than yesterday. Some sleep last night, but not quiet. Pain in back and languor. I hypnotized him and induced catalepsy. Suggestibility increases. After waking he states that he has felt the sensations of sleep. I suggested to him to find his former mistress and perform the sexual act with her, assuring him that he would succeed in it.

May 23d. K. excuses himself for having missed the sitting yesterday by attributing his absence to business. He had followed my advice, and coitus took place to his entire satisfaction. I hypnotize him again, and suggest that he perform coitus this evening with another woman, giving assurance that it would be successful.

May 24th. Yesterday's attempt was perfectly satisfactory. Some months later I received notice of his marriage.

Case 25. *Reported by Dr. Liébeault. Psychical Impotence Improved by Hypnotic Suggestion.*—B., aged 20 years, healthy, has powerful erections when he thinks of the woman he loves, but as soon as he is in her arms he grows so excited that erection is no longer possible.

On the first attempt at hypnosis B. passes into light sleep, and, in five sittings, is so influenced that he is able to perform coitus for some time. Later he relapsed; but he had to leave Nancy, and treatment could not be continued.

Case 26. *Reported by Dr. Liébeault. Impotence Caused by Auditory*

Hallucinations Cured by Suggestion.—L., aged 50 years, with other imperative ideas, has suddenly developed the notion that he can no longer fulfill his marital duties. He hears voices that keep him from it. I succeeded in removing his hallucinations by means of suggestion. Thereafter the patient was capable of intercourse with his wife to his entire satisfaction.

Case 27. *Reported by Professor Bernheim. Psychical Impotence Treated by Suggestion without Success.*—For seven weeks I treated with hypnotic suggestion (second degree) a young man aged 26 years. He was hypochondriacal, sad, and preoccupied with self. He complained, also, of sexual impotence, though there had still been erections for two or three years. Complete failure.

Case 28. *Reported by Professor Bernheim. Psychical Impotence Cured by Suggestion.*—Male, aged 25 years; neurasthenic; has thoughts of suicide. For about two years he has suffered with impotence. His mother is nervous. On the first attempt at hypnosis he passed into deep sleep. He was completely cured in ten days by suggestion.

Case 29. *Reported by Professor Bernheim. Relative Impotence. Probable Success by Means of Hypnotic Treatment.*—A Belgian merchant consulted me three years ago on the following subject: Married three years and loving his wife, he has never been able to satisfy her. Erection incomplete in spite of all efforts. Still, he is not impotent; for, when he makes the attempt with another woman, he can perform coitus three times in a night. Patient is 38 years of age, in good health, and without nervous antecedents. Probably the emotional excitement on the marriage-night, on the first attempt, paralyzed erection, and unconscious auto-suggestion, on each new attempt, reproduces, to a certain extent, as a reflex act, the paralysis of the genito-spinal centre. I hypnotized the patient easily. Deep sleep, with partial post-hypnotic amnesia. He could remain in Nancy but three days. I gave him six hypnotic sittings, and made him promise, in case of failure with his wife, that he would return, that an attempt might be made again under the direct influence of new suggestive treatment. The patient departed, and no word was received from him. He was probably cured (von Schrenk).

Case 30. *Reported by Professor Bernheim. Psychical Impotence Cured by Suggestion.*—X., laborer, of Nancy, in November, 1890, seeks my aid on account of impotence. He had never been able to perform coitus. Erections, especially at night; great desire to perform coitus. He wishes to marry; but every time he visits a woman erection fails to occur. He is tall, aged 26 years, of good constitution, very nervous and impressionable. He often suffers with sleeplessness. His mother, also, is said to be nervous. He states that he has never been ill and has never masturbated. His genitals are well formed.

I hypnotized him. He passed easily into the second stage (catalepsy, automatism, memory after waking). Later he passed into somnambulism several times without memory on awaking. I hypnotized him daily for fifteen days. Sleep at night returned. Nervous excitability diminished, but impotence continued in spite of all efforts. I continued the treatment once or twice a week for two or three months. In March, when I recognized that in this way I should obtain no immediate result, I sought to strengthen the idea in him that he was perfectly cured, but that he must not make further attempt at coitus. "One fine day, without your thinking about it, this thing will take place of itself." I had him visit me every ten or fifteen days, and each time I suggested to him that the cure would take place without his thinking about it. In July, 1891, he informed me that he had been successful. While sleeping with a woman he had no erections during the night, but in the morning he was able to perform coitus twice. I enjoined him not to abuse his powers and to wait patiently for complete cure. Six months later he learned to accommodate himself to his erections, and he no longer felt powerless in the presence of a woman.

Case 31. *Reported by Professor Bernheim.*[1] *Psychical Impotence Cured by Hypnotic Suggestion.*—X., merchant, aged 27, consulted me October 10, 1889. He came from the Urals, and was several weeks on the way before he found me. He complained of absolute impotence and had never been able to perform coitus. At the same time erections are powerful, but in the presence of a woman he begins to tremble with excitement and erection disappears. It is apparently a case of psychical impotence; mental excitement has an inhibitory effect. Besides, he tells me that he has masturbated a few times, but rather unconsciously, at night in sleep. Sometimes this would occur three nights in succession, then it would not occur again perhaps for ten or fifteen days or more. X. seems very nervous. He is very impressionable; he speaks often suddenly and easily begins to tremble. In his excitement he shoots beyond the mark. His constitution is excellent. He has never been ill, and has always been free from nervous disease. Examination negative.

I easily succeeded in placing him in deep sleep. I suggested physical and mental rest. "There will be no inclination to masturbate at night; in the presence of a woman erection will last until the completion of the act, without the occurrence of excitement. You will be cool, have no trace of fear, and be able to perform the act." The patient was able to remain in Nancy only from October 10th to 23d, when his vacation expired. I repeated the same suggestions daily. After the first sitting he masturbated no more at night. Once, on the night of October 13th, he awoke with his hand on his penis and was about to masturbate; he immediately stopped, and the act has not been repeated.

[1] Hypnotism, Suggestion, etc., Paris, 1891, p. 336.

October 20th, at suggestion, he attempted coitus, when he noticed that fear and tremor did not come as formerly. Therefore he thought his object nearly attained. I suggested to him now energetically repetition of the attempt on October 22d, with the assurance that he would have complete success this time. October 23d he told me of his success, the first of the kind in his life. Though erection diminished toward the end of the act, yet he was still able to complete ejaculation. Now I suggested that, once freed from his excitement, in the future he would make no failures. He returned home satisfied.

Case 32. *Reported by Dr. Moll*,[1] *Berlin. Functional Impotence Cured by Hypnotic Suggestion.*—J., aged 31, noticed nine months ago that in coitus he had ejaculation either before immissio penis in vaginam, or that when it took place at the proper time ejaculation was devoid of pleasurable feeling. After about forty trials I was successful in hypnotizing the patient so deeply that with eyes closed he was obnoxious to the most various suggested hallucinations. After this, the attempt, repeated for several days, to induce him to perform coitus by post-hypnotic suggestion, was so successful that within four days the patient was able to perform coitus twice with immissio penis and normal lustful feeling. Unfortunately, I lost sight of the patient, who showed no objective signs of disturbance of the sexual organs or nervous system; for in the second coitus he acquired gonorrhœa after having dispensed with preventive measures, against my advice.

Case 33. *Personal Observation. Functional Sexual Weakness Treated in One Sitting by Suggestion without Success.*—T., aged 31. Father nervous. Had measles ischias lasting two or three years, but no other diseases. Masturbated since his twentieth year. After self-abuse continued five years, first attempt at coitus; ejaculatio præcox with incomplete erection. States that he has not masturbated for a year; often awakes in the morning with complete erection. Pollutions at night once or twice a week. Moderate hyperæsthesia of the glans. Neurasthenic complaints; easily tired; tinnitus aurium. Great weariness on awaking in the morning; rising requires great resolution. Cardiac palpitation. Depression, with entire loss of self-confidence. Patient was never in love. Genitals normally developed. Water, electricity, and sounds have been used for his psychical impotence in vain. Patient was sent to me by Dr. Kopp. January 12, 1891, first attempt at hypnosis. T. has an idiosyncrasy against hypnosis. He cannot make himself passive; consequently, allows his attention to be diverted, and conceals his apparent anxiety and excitement by effectual resistance. On January 13th the patient writes me that it is impossible for him to overcome his idiosyncrasy, and therefore will not take any further treatment.

[1] Reported by Caspar, Impotentia et sterilitas virilis, München, 1890, p. 99.

Of course, the negative result of a single trial is of no value in answering the question whether and in what length of time psychical impotence can be cured by suggestion. In spite of the prejudice of the patient in the foregoing case, the prognosis with psychical treatment did not seem to me at all unfavorable. A series of sittings would have taught the patient to submit to the influence, and thus his suggestibility would have proportionately increased. The gradual occurrence of quiet by means of suggestion, and the removal of neurasthenic symptoms in connection with careful attempts at coitus, in my opinion would have brought about a cure in spite of the difficulties.

Case 34. *Personal Observation. Impotentia Paralytica (?) Treated Experimentally in Four Sittings. Temporary Improvement.*—Male, aged 41. Mother died of heart disease. Father and brothers and sisters living and healthy. B. has never had other illness than the diseases of childhood and emphysema that causes little trouble. From his tenth to his sixteenth year he practiced onanism excessively. As a result, irritable weakness of the lumbar cord came on. Frequent pollutions in climbing, riding, and in sleep. B.'s hyperexcitability is so much developed that when he merely thinks of a woman ejaculation results with a relaxed or half-erect organ. In attempts at coitus, ejaculatio ante introitum vaginæ; immissio has never been accomplished, though in previous years, especially nights and mornings, erections were not infrequent. The patient can only recall having had one actual erection in the last two years. Nevertheless, in the last four years he had attempted coitus four times, always with great psychical excitement. There is pain in the back after pollutions, which still occur frequently. Besides great depression there are no other abnormal nervous symptoms. Genitals normally developed.

The patient has tried in vain all kinds of treatment at the hands of celebrated specialists,—hygienic, electrical, medical, hydropathic,—and now, as a last resort, wishes to try suggestion, thinking that his impotence may be of psychical origin; that, if his excitement on attempting coitus can be overcome, perhaps he will succeed. In spite of an unfavorable prognosis, in order not to destroy all the patient's hope, I made four hypnotic attempts from September 16 to 19, 1889. In these sittings the patient did not pass beyond slight somnolence. On the night of September 16th and 17th he noticed the beginning of erection, which increased the next night. Attempt at coitus September 18th. Weak erection made immissio penis in vaginam possible, but only for a short distance. But ejaculation took place in the vagina. On Septem-

ber 19th the patient was called away from Munich, and could only be discharged as essentially improved. In spite of the unfavorable conditions, owing to the slight improvement, continuance of treatment would have been advisable.

Case 35. *Personal Observation. Psychical Impotence Essentially Improved in Three Hypnotic Sittings. Favorable Prognosis.*—K., aged 29. No hereditary taint. Parents and brothers and sisters healthy. Diseases of childhood,—scarlet fever, dropsy, scabies, till his twelfth year. He began masturbation in his fourteenth year, taught by a companion, and he practiced it daily until his twenty-first year, always fancying himself in the sexual act with women. Onanism less frequent since his twentieth year, and abandonment of the habit since his twenty-fourth year. The patient has never noticed any injurious effect from the vice on his physical or mental health. Physically he seems entirely healthy. Pollutions every three or four weeks. Nights and mornings erections are frequent, and they also occur during the day at thought of a woman. In spite of numerous attempts, the patient has not been able (in ten years) to perform immissio penis and complete coitus. Ejaculatio præcox and relaxation of the organ before introduction have made all attempts futile. His libido sexualis is very intense; he loves a girl and wishes to marry, but the thought of failure has become an imperative idea. At each new trial there is such intense psychical excitement that he breaks out in a perspiration. The patient came to consult me September 26th, and, though desiring help, he was so much under the influence of auto-suggestion that he could not be hypnotized. First trial, September 26th. Very slight somnolence. He denies the influence and wants to be put in a deeper sleep. On this occasion quiet and success in coitus were suggested. On the same day he sought a puella, but immediately lost his libido when he saw her padded breasts while undressing. The first trial was a failure, because no erection occurred in spite of tactile stimulus.

After a time, second trial. For the first time in his life the patient succeeds in bringing about immissio penis, but ejaculation took place with a relaxed organ immediately after its introduction; so that there was no gratification, though the emission took place in the vagina. Nevertheless, this is to be regarded as some progress.

September 27th the hypnotic procedures had a negative result, as did another attempt at coitus. At the door of a brothel the patient is overcome with fear and repugnance, and turns away.

October 4th, third hypnotic trial with the help of chloroform to overcome the unconscious but obstinate resistance. K. passes into the stage of excitement, which, by suggestion, I transform into hypnosis. Suggestive cataleptic symptoms. Energetic suggestion that coitus will be successful. On awaking the patient declares that he has not been influenced in the least, but he has but a partial memory of it. He is

still possessed by the imperative idea that he cannot be hypnotized. An attempt at coitus on the same day was a fiasco. Since the patient can come only once a week, owing to his living out of the city, therefore he proposes to take a vacation for several weeks, that suggestions may be repeated daily and thus have a more powerful effect on his condition. In spite of the three first trials, the patient is but little improved. Considering his general condition, age, etc., the prognosis seems favorable. Before his departure I assure the patient that with a regular continuance of his efforts certainly coitus will gradually become successful; that he must not allow himself to be discouraged by failure.

November 15, 1891, the patient writes: "Unfortunately, I have not yet had any completely satisfactory results, though I must confess that since my first visit to you I have made some progress. I regularly have half an immission and can make five or six movements, but emission takes place after three or four. It is my intention to continue my efforts this winter by myself, and then next year to take your treatment. I think then to have success in a week."

January 30, 1892, the patient writes: "After many attempts with this single person, I was so far successful that, with proper approach, I was able to perform the act fully. However, whether I could perform coitus with others at any time seems doubtful to me. As soon as I can subject myself to further suggestive treatment at your hands, I think I shall be completely cured."

In this case absolute impotence has become relative. The improvement of November, which in the table is given as slight improvement, has become a relative cure, due to suggestive treatment.

Case 36. *Personal Observation. Relative Impotentia Cœundi Psychica with Neurasthenic Symptoms. Suggestive Treatment. Negative Result with Reference to Sexual Weakness; Positive with Reference to the Nervous Symptoms.*—X., aged 36, landed proprietor, married, childless. Parents, especially father, nervous. In youth, masturbation. Patient very much "spoiled" in rearing; anxious about his health to the extent of silliness. Constantly in fear of apoplexy because of congestive symptoms due to rich food. Strongly built, large, abundant adipose. Internal organs, lungs, heart, without demonstrable disturbance; sometimes nervous, disagreeable cardiac palpitation. Abdominal organs normal. Penis and testicles somewhat small, but, according to statement of physician, functionally capable. Trials have proved this. Sleep and appetite, with few exceptions, excellent. In short, the patient may be called a healthy man physically; on the other hand, his great anxiety is a mental abnormality, causing changing hypochondriacal moods with rela-

tive impotence. Energetic advice and dietetic rules have, thus far, always had a good influence, but have been insufficient to bring about cure. Aphrodisiacs (mild) proved worthless. This from his physician, who sent him to me October 17, 1889.

The patient was remarkably anxious and very reticent in his communications. Therefore, on the first day it was not possible for me to learn the details and causes of his psychical impotence. The first sitting, therefore, could be regarded only as a test whether the patient was susceptible to suggestions or not.

With the use of the method of Bernheim and Liébeault, the patient passed into somnambulism. Complete hypotaxis, suggestive catalepsy, and post-hypnotic amnesia. Decrease of nervous excitability and anxiety and disappearance of palpitation suggested. Success in coitus in the future. The patient left the same day. The effect on his general condition was favorable. According to the statement of his physician, the patient was much improved by the sittings held during the next week; was less excited, and made no complaint. Still, his impotence remained unchanged, as I had foreseen. The patient could not follow my advice to submit himself to treatment for several weeks for his impotence.

On the occasion of a visit to his home, October 27th and 28th, I hypnotized the patient twice, with the same success as on the 17th. Again, according to the physician's statement, the suggestions quieted him and improved his condition, without having any special influence on his sexual sphere. In a letter of December 7, 1890, the physician reports his condition as "very satisfactory."

The foregoing case, on its negative side, is not especially instructive. As I learned in the course of treatment, the patient was able to have congress with other women, but not with his wife. His wife seemed to be a natura frigida; at any rate, she does not know how to respond to her husband. In such a delicate case, as long as there is no sympathetic assistance on the part of the wife, the treatment of the husband alone must remain fruitless.

In such cases it is always the part of the physician to prepare the wife mentally, eventually by means of hypnotic suggestion; that is, to remove any possible indifference or want of proper interest constituting a mental impediment. I am convinced that in the foregoing case the married life could be made happier if both parties could be subjected to systematic treatment.

Case 37. *Personal Observation. Impotentia Cœundi Psychica on a Neurasthenic Basis Cured by Suggestion.*—A. B., aged 33, physician, without hereditary taint. The patient has had no severe diseases aside from typhus in his youth. Sexual desire appeared in his tenth year. From this time, onanism without noticeable effect on the nervous system. Abandonment of the habit with the beginning of hetero-sexual intercourse. Congress was successful without especial difficulty till his thirtieth year. Patient is without libido nimia, moderate on the whole. Gonorrhœa, which lasted a long time, made coitus impossible for a long period. After recovery, hyperæsthesia of the glans remained, with irritable weakness of the sphincter vesicæ. On attempting coitus, violent mental excitement, with feeling of anxiety; erection impossible. Impotentia cœundi. The patient was treated for a long time by noted specialists with cold sounds, electricity, etc., without noticeable success.

B. is about to become engaged, and is unhappy over his condition, which constantly takes up all his thoughts. His sleep is undisturbed, though he has erections and pollutions. At Professor Forel's advice, he seeks help from me by means of hypnotic treatment.

October 29, 1889, first attempt. Complete hypotaxis, suggestive catalepsy, and impossibility to voluntarily overcome contractures. Patient quieted by suggestion; prospect of complete virility given with diminution of the troublesome sensations. No post-hypnotic amnesia. On the same day coitus is twice performed with a prostitute without the former excitement.

October 30th. The hyperæsthesia, which compels the patient to think constantly of his trouble, is unchanged. Second hypnosis; suggestions the same as on the 29th. Sexual congress again to-day; complete erection, but ejaculation premature.

October 31st. Hyperæsthesia unchanged. On this day and on November 1st removal of his attention from his own person energetically commanded; other suggestions the same. The patient thinks less about his condition; weakness of the sphincter of the bladder does not cause any more complaint; simultaneous diminution of the hyperæsthesia, though it is still present. Business calls the patient away before conclusion of treatment. He wrote me December 3, 1889, that "shortly before taking the train I performed coitus perfectly," but, unfortunately, he contracted gonorrhœa, which prevented further efforts. At the conclusion of his letter the patient expresses a desire to return to Munich, as soon as circumstances allow, to perfect the success already obtained. When I met him, about a year later, the patient informed me that he required no further treatment after his recovery from the gonorrhœa. Power continued permanent, and the troublesome symptoms gradually disappeared.

In the foregoing case, in four hypnotic sittings, all that was possible was attained; that is, by removing the psychical inhibition the patient was lastingly convinced of his sexual power, which exercised a favorable influence on the hyperæsthesia, also probably due to psychical causes.

The patient owes his cure to suggestion. It was permanent. Exactly two years later, in October, 1891, the patient relapsed as a result of severe nervous disease.

Case 38. *Personal Observation. Impotentia Cœundi Psychica et Nervosa Irritativa (Atonica?) of Twelve Years' Duration Cured in Two Months by Suggestive Treatment.*—S., aged 34. Mother died of dropsy, father of tuberculosis. One sister healthy, a second has diseased eyes. Maternal uncle and his son epileptic. S. was healthy as a child. At the age of 15 was manustuprated by a servant-girl; this led him to mutual onanism, without, however, allowing the boy to perform immissio penis. "I stood," as he said, "at the well without being able to dip from it." This intense excitation of his libido sexualis led him to auto-masturbation, which for the first two or three months he practiced two or three times a day; later, several times a week. At 18 he practiced it but once a week. At that time he reveled in lascivious pictures, and increased his power of fancy by looking at obscene photographs and artificially retarded ejaculation in the onanistic act. As a result, intense sexual hyperæsthesia, infrequently ejaculation through mental stimulus alone with intense lustful feeling. At the age of 22 he gave up masturbation. First coitus fairly successful, but without the expected satisfaction. He was much occupied with erotic thoughts, and from this time experienced impotence growing more and more pronounced. He remembers to have performed coitus only once with complete satisfaction, and that with an attractive servant-girl. Defect and want of erection, premature ejaculation, sometimes with relaxed organ, and diminution and complete absence of pleasurable feeling sent him, at the age of 23, to physicians; and he has now been treated for eleven years without any essential change in his condition, and that in spite of a favorable prognosis in general. Hydropathic and electrical treatment in all possible forms fruitless. In 1889, gonorrhœa from an attempt at coitus, which lasted till February, 1890. Orchitis due to the use of sounds (?), but probably the result of the gonorrhœa. Previous to beginning treatment with me, careful treatment with bougies for five months with galvanism. Gymnastic exercises, in spite of prescription, were not carried out systematically enough.

The patient appears intelligent, but his memory has suffered much. Depressed, confused; want of energy, incapable of determination, a cer-

tain apathy. He has no interest in anything. Phlegmatic temperament. Very corpulent. Genitals fully developed. Right hernia; tendency to it on the left side. Penis short and thick; glans blue and remarkably insensitive. Both testicles sensitive to hard pressure. Left epididymitis; cord harder than usual on palpation. Spermatozoa are present, but with diminished vitality. It is also demonstrated microscopically that there is no remnant of gonorrhœa. Patient has occasional pollutions (about once a month), especially frequent nights and mornings, sometimes during the day, with powerful erections. His libido sexualis is very lively, but in attempts at coitus inhibitory ideas and feelings of anxiety (fear of infection, of impotence) are so dominant that erections do not occur, and his libido is changed to an irresistible disinclination for the act. The merest trifle—want of neatness in the puella, etc.—may call the inhibitory mechanism into action. Looked at from this stand-point, especially considering the erections and the living spermatozoa, the patient, as all physicians have declared, has impotentia cœundi psychica; but he also certainly exhibits the result of onanism (as described above) in signs of irritable weakness, as well as a diminution of virility manifest in his character, which depends not only on psychical inhibition, but is in contrast with his intense libido sexualis. The want of lustful feeling and anæsthesia of the glans are due undoubtedly to the hyperexcitation of the reflex arc by onanistic excesses. Therefore, the diagnosis is impotentia cœundi nervosa irritativa et psychica.

October 1, 1891, first hypnotic attempt. Somnolence which, from sitting to sitting, aided by darkness and a pleasant reclining attitude, is deepened to sleep. Suggestive catalepsy. During October daily hypnotic sittings, lasting from one-half to three-fourths of an hour. Suggestions: Self-confidence in coitus; assurance of success in it; increasing pleasure; pleasanter mood. Daily repetitions of these suggestions. Frequently, after the end of these sittings, erections and libido sexualis occur. During the night of October 14th the patient had a pollution, with increased pleasurable sensation.

October 18th, on the way to a brothel, he was seized with fear of making a fiasco. He turned back; depressed. During the first half of October, two visits to a puella without the occurrence of erection. Forbidden to induce erection by tactile stimulation. During October the patient had powerful erections either at night or on waking in the morning, sometimes during the day.

October 27th, first attempt at coitus. On my advice, the patient waited (without tactile stimulation) for the spontaneous occurrence of erection. After it came on, perfect immissio penis, but disappearance of the erection during the act. Thereafter help at the hands of the puella. Then followed correct performance of the act, with ejaculation at the proper time (neither premature nor retarded), and a feeling of satisfac-

tion, even though the intensity of lustful feeling was not up to what the patient desired. Post-coitum and the next day, a feeling of repugnance at thought of sexual congress, with depression. The sexual indifference disappeared in two days. Awakening of self-confidence by suggestive stimulation. Early in November renewal of erections. After November 5th, faradic penciling of the glans to increase sensation.

November 9th, a visit of two hours with a puella without the occurrence of erection. Depressed by the failure. The night of November 12th the patient spent with a puella. Again complete failure. The assurance that he had not made a proper choice, and daily treatment with faradic electricity and hypnosis caused the patient to make a new attempt with a prostitute known for her attractive qualities. During the night of November 20th, which he spent with her, erection occurred spontaneously. Complete immissio penis. Continuance of erection. Friction was really felt, and ejaculation was not premature. More lustful pleasure than usual, but still not intense enough to satisfy the patient. The mechanical part of the act had been perfectly successful. The patient is happy; self-confidence increases. The next day after the act erection occurred twice, in complete contrast with the repugnance for everything sexual which had previously occurred and lasted several days after such an attempt. Treatment with hypnosis and electricity continued.

November 24th, he comes and delightedly reports that he had performed coitus the preceding night to his entire satisfaction. Erection spontaneous and continuous, without any aid; immissio penis and ejaculation perfectly normal. This time the patient experienced a pronounced lustful feeling. Erection occurred five times on the day following this attempt. He had experienced nothing like this in ten years. Performance of coitus again on the night of November 26th, with the same success.

Since the patient has performed coitus perfectly three times in the last three weeks without depressing or weakening effect, he can be discharged as essentially cured. In other respects the hypnotic treatment has benefited him. He was hypnotized twenty-six times, and electricity was used twenty times.

I take the following from notes of his condition sent me by the patient:—

"The undersigned, who was under medical treatment for twelve years for impotence, without having received the slightest benefit, began suggestive treatment September 30th. Suggestion exerted a beneficial influence at once, for erections occurred normally and more frequently than formerly. After a week a pollution occurred, which was repeated in four or five days, while of late years such an event was extremely

infrequent. About the end of November it became possible to perform coitus three times in seven days. On the second occasion lustful pleasure was perceptibly greater than the former minimal pleasure. The disease which for twelve years defied medical art may be regarded as cured by suggestion.".

Several months after discharge the patient wrote me that the power of erection had only increased after his departure (every night three or four erections, sometimes five or six). He performed coitus repeatedly satisfactorily in all respects; on some occasions it was not completely successful, for which he blamed the other party. Later, he contracted gonorrhœa. Thus, the power of erection and to perform coitus remained perfect in all essential points after discharge. The patient, therefore, may very justly be regarded as cured.

Concluding Remarks.

As the table (next page) shows, of 18 patients there were:—

Cured, { with later report, . . . 4 / without later report, . . 6 }	10	=	55.56 per cent.
Essentially improved, ...	1	=	5.56 per cent.
Slightly or temporarily improved, .	2	=	11.11 per cent.
Treated without success, ...	5	=	27.77 per cent.
	18		100.00 per cent.

Of the 18 patients, 6 passed into somnambulism, 5 into hypotaxis, and 3 into somnolence; in 2 cases hypnosis could not be induced. One patient was treated in the waking state. In another case the degree of hypnosis was not given. No case in a female was treated. The number of sittings varied from one to fifty-six. Ten patients were cured. According to the foregoing figures, the prospect of success in the treatment of functional or psychical impotence by hypnotic suggestion is 60 per cent. At the same time, it should be remembered that in some cases systematic treatment could not be carried out; and that other cases, owing to the want of success by other methods of treatment, are to be regarded as having been given up or as especially difficult.

Almost all impotent individuals (according to Fürbinger, without exception) are neurasthenic, and are, therefore, difficult

to hypnotize. The increased sensitiveness to auto-suggestion, the result of irritable weakness of the brain, may be regarded as a direct symptom of the neurasthenia. The inhibitory imperative idea of sexual inability, as an auto-suggestion, especially resists suggestion from without, if it is not possible so to mask the psychical procedure that the brain, in spite of mistrust, will accept it; or if the psychical erethism, which is constantly or occasionally present in the majority of neurasthenics, prevents the necessary concentration of the attention and the beginning of the hypnotic state. To hypnotize neurasthenics is one of the most difficult tasks for the psycho-therapeutist, demanding great circumspection, practice, patience, and time. Only after forty sittings (Case 31) did Moll succeed in inducing hypnosis deep enough to permit the suggestive induction of the most various hallucinations. In one of my patients (Case 33) the disinclination to be hypnotized (probably as a result of perverse ideas connected with it) was so great that the patient would not allow a second attempt. In another case (35) the patient had convinced himself (auto-suggestion) that he could not be hypnotized, and I required the assistance of chloroform. This imperative idea was so strong that, in spite of partial amnesia after waking, the patient declared that he had not been influenced in the least.

The word "hypnosis" and the prevalent opinions concerning it lead many patients to believe that sleep is necessary for the success of the therapeutic suggestions; and there is no idea of sleep for them when, after waking, they remember the events of the hypnosis. Though sleep favors the objectivity of suggestions, it is not necessary, and actual sleep occurs in only about a third or a fourth of all patients hypnotized. Many somnambulists are minds awake, but without memory after the hypnosis; they speak, walk, and do not present the appearance of sleep in any way, but think that they have slept because they remember nothing. The opposite of this illusion of sleep is presented by those persons who actually appear to sleep,—dream, snore, etc.,—and still, after waking, protest that they have not been really asleep. Such patients often have but an

indistinct memory of the events of the hypnotic state, and are often deceived concerning the time sleep has lasted. How little weight is to be given to the memory of patients in this state of self-deception is shown by the fact that suggestion may awaken or destroy post-hypnotic memories. The word "hypnosis," in its reference to sleep, does not comprehend clearly enough all suggestive phenomena. Therefore, I can only agree with Professor Bernheim when he suggests that the word "hypnosis" be abandoned, and proposes as a substitute the expression "state of suggestibility."

The false views which neurasthenics especially have formed of hypnotism, which they often look upon as dangerous, may be the starting-point of bad effects due to auto-suggestion, which, however, have nothing to do with hypnosis *per se*. In the cases reported there were no unfavorable effects of any kind; on the contrary, in cases where the impotence was not affected, the influence on the general condition and nervous symptoms was favorable.

After the details set forth in this section there can no longer be any doubt that, if need be, in psychical and functional impotence, suggestive treatment in hypnosis is indicated as the most effectual procedure in psycho-therapeutics, and that henceforth it should be more extensively used and receive more careful consideration than heretofore.

III. SEXUAL PARÆSTHESIA.

CHAPTER VII.

THE FORMS OF SEXUAL PERVERSION WITH REFERENCE TO THE THEORY OF PROFESSOR VON KRAFFT-EBING.

Definitions and Classification.—Von Krafft-Ebing designates sexual paræsthesia as the excitability of the sexual instinct to inadequate stimuli. Every expression of sexual desire which does not correspond with the purpose of nature—procreation—is perverse. This manifestation of the sexual impulse often occurs in connection with hyperæsthesia, and may find satisfaction with the opposite or the same sex; in accordance with which von Krafft-Ebing distinguishes hetero-sexual perversion and homo-sexuality. The impulse toward the same sex with diminution or entire absence of feeling for the opposite sex is, in accordance with Westphal's [1] suggestion, called "contrary sexual feeling." By this expression Westphal means that the phenomenon does not always affect simultaneously the sexual desire as such, but that merely the feeling, the whole inner disposition, becomes different from that of the sex, as a simultaneous, undeveloped degree of the pathological phenomenon. In our opinion, to which we shall later recur in more detail, in all genuine cases of contrary sexual feeling the sexual instinct is implicated; so to speak, it is the starting-point, the centre around which all other symptoms are grouped. Therefore, changes of character approximating that of the opposite sex, without implication of the sexual sphere, do not seem to us to deserve the name of contrary sexual feeling.

In the manifestations of paræsthesia sexualis, according to their practical significance, we differentiate two groups:—

I. Inversion of the sexual feeling (contrary, or homo-sexual, feeling).

[1] Westphal, "Conträre Sexualempfindung," Archiv für Psychiatrie, Berlin, 1869, Bd. II, Heft 1, p. 107.

II. Perverse activity of the sexual impulse (without reference to the object.)

I. *Inversion of Sexual Feeling.*[1]—Group I is divided by von Krafft-Ebing into two important classes:—

(*a*) Acquired abnormal contrary sexual feeling.

(*b*) Congenital abnormal contrary sexual feeling.

The prerequisite for the development of homo-sexuality is a neuropathic nervous system (Moll and von Krafft-Ebing), which may be either acquired or congenital. Besides the predisposing cause,—the neuropathic condition, according to von Krafft-Ebing,—there must be an exciting cause, to induce the manifestation of contrary sexual feeling. According to the same author, as an acquired abnormal phenomenon, it occurs but infrequently. He gives only four cases[2] as the result of cultivation, in contrast with forty-three cases in which inheritance plays a *rôle.* Acquired contrary sexual feeling passes through the same stages as does the congenital. In development the following varieties are to be differentiated (von Krafft-Ebing):—

1. With predominating homo-sexual feeling there are traces of hetero-sexual feeling (psycho-sexual hermaphroditism).

2. There is inclination only toward the same sex (homo-sexuality), horror feminæ (limited to the vita sexualis).

3. The whole mental existence (character) corresponds with the abnormal sexual feeling (effemination and viraginity[3]).

[1] In the eighth edition of Psychopathia Sexualis, von Krafft-Ebing distinguishes four stages in the process of transformation of sexual feeling:—

I Degree: Simple inversion of the sexual feeling. The patient is still in an active *rôle*, and looks upon the impulse toward the same sex as an aberration.

II Degree: Eviration and defemination. Transformation of the character, the feelings, and the inclinations to those of a female, or *vice versâ*.

III Degree: Transformation to metamorphosis sexualis paranoica. The bodily feeling changed in the sense of a transmutatio sexus.

IV Degree: Metamorphosis sexualis paranoica. Delusion of sexual transformation.

[2] In Moll's opinion (*loc. cit.*, p. 157) of these four cases, three are not proof of the theory of cultivation, for in them there were traces of perversion during childhood and puberty.

[3] Tarnowsky (Die krankhaften Erscheinungen des Geschlechtssinnes, Berlin, 1886, pp. 11–14) describes the development of effemination as follows: "The first expression of shame is not in relation to girls or women, but toward grown men. The boy is ashamed to undress before a grown man. Dreams with pollutions are of embracing, kissing, and caressing men. Owing to the irritable weakness of these subjects, their love is violent and passionate. The youth is actuated by the desire to appear feminine, loves to put on female attire, to wear his hair long, and to go about with open neck and laced waist; he

4. The bodily form approaches that with which the abnormal sexual feeling corresponds. There is never, however, actual hermaphroditism (androgyny and gynandry). Feminine type (broad hips, rounded form, abundant development of adipose tissue, growth of beard spare or absent, feminine features, fine complexion, falsetto voice) in the male; development of mammæ, with production of milk at puberty (Case 80, "Psychopathia Sexualis").

As the most important influences contributing to the development of acquired contrary sexual feeling, the authorities mentioned enumerate: excessive masturbation, which injures character, instincts, and nervous system, and leads to mutual masturbation; and fear of pregnancy and venereal infection. Moll regards as acquired contrary sexual feeling only those cases where there was first manifested an inclination toward women, and later toward men.

When the inversion of sexual feeling appears as a partial manifestation of a "neuro-psychopathic" condition which is hereditary, the following signs are, according to von Krafft-Ebing's theory, distinctive:—

(*a*) Premature awakening of the sexual instinct.

(*b*) Enthusiastic exaltation; overpowering strength of desire; sexual hyperæsthesia.

(*c*) Functional and anatomical signs of degeneration.

(*d*) Neuroses (hysteria, neurasthenia, epileptoid states); irritable weakness of the lumbar portion of the spinal cord.

(*e*) Psychical anomalies (original eccentricities and deficient intellect, with one-sided mental endowment), even to the extent of weak-mindedness and moral insanity.

likes to perfume and powder himself, and to paint and pencil the eyebrows. There is developed that type of feminine male so disgusting to men and so repugnant to women, whom it is not difficult to recognize in the outward appearance. Of medium or small build; with broad pelvis, narrow shoulders, feminine gait, and a peculiar movement of the hips; with smoothed locks and ludicrous attire, the arms bearing bracelets; with smirks and gestures and volubility, they seek to attract the attention of men. The unfortunate creature, especially if he have a relatively weak mental endowment, does not understand that he is the more disgusting to normal men the more he seeks to imitate women. Since he is whimsical to the verge of hysteria, cowardly, pusillanimous, vindictive, and willful, he unites in himself all the defects of woman without her virtues, and possesses not a single one of the attractive features of the male character. Therefore, he is as repulsive to men as to women."

(*f*) Neuroses, psychoses, and signs of degeneration in progenitors.

"The hereditary element is the acquired abnormal inclination to the same sex, which in descendants is manifested as a congenital abnormal phenomenon." This hypothesis is supported by the facts that mental peculiarities and defects may be transmitted, and that individuals of contrary sexuality may beget children. In an observation by von Krafft-Ebing, father and son are affected with contrary sexuality.

According to von Krafft-Ebing, the first three degrees of congenital contrary sexual feeling correspond genetically with the developmental stages of the acquired anomaly.

The most frequent sexual acts in which such individuals find satisfaction are: coitus inter femora, in anum, in os; mutual, psychical, and tactile onanism; simple caresses; exhibition. Enforced intercourse with a woman is burdensome, while inadequate homo-sexual acts afford complete satisfaction. As a rule, there is no inclination toward immature individuals.

In homo-sexual intercourse the *perverse activity of the sexual instinct* may take the same form as in hetero-sexual relations; the manner of expression of the instinct and the excitation of it by means of partial impressions coming from the beloved object are the essential elements, while the sex of the individual giving rise to the impressions is subsidiary.

According to von Krafft-Ebing's brilliant explanations, in the various forms of this anomaly the combination of lust and cruelty is very striking. The two most intense emotions, love and anger, seek to expend themselves physically on their object; both throw the psychomotor sphere into violent excitement, and through this excitement attain their normal expression. Exaltation of the sexual emotion induces intense excitation of the whole psychomotor sphere, and gives rise to the impulse to exhaust itself in senseless and seemingly hostile acts, which are to be regarded, in a measure, as accompanying psychical emotions. The most powerful means with which to affect an individual are those which inflict pain. The aggressive *rôle* of the man may, where there is defect of moral feeling and absence of

normal deterrents, become so intensified as to end in the murder of the object of love. This pathological intensification of the manifestations accompanying the vita sexualis, following French usage, von Krafft-Ebing designates *sadism*. Acts of violence are colored with lustful feelings.

Pathological predominance of the specific feminine element, the instinct of subordination, to the extent of desire to endure pain and to submit absolutely to its power to the extent of experiencing lustful pleasure in abuse (overcompensation of physical pain by psychical lust), the same author calls *masochism*.

The terms *sadism* and *masochism* are derived from the names of the novelists, Marquis de Sade and Sacher-Masoch, who described the perversions. Even should these terms be adopted,—although they do not follow the usual rules of scientific terminology,—it seems essential to form a word the composition of which shall indicate the nature of these sexual anomalies. Such a word is offered in the term *algolagnia*, or *algolagny*, derived from ἄλγος = pain (adopted medically in this sense, as in analgesia, cephalalgia, and neuralgia) and λαγνός = sexually-excited lust; from the latter λαγνεια is derived, used by Hippocrates and Aristotle in the sense of seminal emission, by Xenophon in the sense of lust (Max Offner[1]). While algolagnia would designate the combination of cruelty and lust as a special variety of sexual perversion, *active* algolagnia would signify sadism, and *passive* algolagnia masochism (masochist = passive algolagnist, and masochistic = passively algolagnistic).

Lustful pleasure in inflicting pain and lustful pleasure in the endurance of pain are but two aspects of the same mental process, of which, according to von Krafft-Ebing, the essential element is the consciousness of active or passive subjection. Passive algolagnia in a man is the development of a sexual characteristic which, in accordance with her nature, belongs to woman, and it is to be regarded as partial effemination or rudimentary contrary sexual feeling. Cruel acts are the most intense means with which to express the relation of subjection.

[1] Max Offner, whose philological knowledge assisted in the formation of the above word, also proposed the terms "æklalagnia" = masochism, and "æklzolagnia" = sadism (from αἰκια and αἰκιζω), but they seem to me less suitable.

Though active and passive flagellation is the means most frequently used as an excitant by algolagnists, still there are other cases in which the relation of subjection is, to a certain extent, indicated symbolically, and as an accessory group of psychical hermaphroditism are those cases in which the passive inclinations of algolagnia are combined with others that are active.

The last group of phenomena of paræsthesia sexualis is designated "erotic fetichism" (von Krafft-Ebing and Binet), *i.e.*, individual valuation of the fetich—a part of the beloved person—to the extent of actual enthusiasm. Here the essential element is the emotional coloring of the idea of a portion of the beloved person, in a sense of sexual pleasure, which is peculiar to the individual. For the development of this form hyperæsthesia is necessary, and the substitute for coitus is usually found in onanistic acts.

Von Krafft-Ebing avails himself of Binet's theory of association to explain this variety of perversions. Sensual excitement occurs simultaneously with the sight of a portion of the beloved person. Sensory and optical impressions are associatively connected, and this connection is confirmed in proportion as frequent repetition of the feeling arouses the optical memory-picture. The fetich is an individual symbol which induces sexual excitement. It may consist of (*a*) a portion of the body (hand, foot, hair); (*b*) peculiar mental characteristics; (*c*) lifeless objects, articles of use which, as a rule, originally stood in some relation to "*a*" (derived from); as, for example, aprons and shoes. Von Krafft-Ebing, however, classifies shoe-fetichists as masochists (passive algolagnists), because the act of allowing one's self to be trod upon expresses masochistic desires.

Fetichism becomes pathological as soon as it is no longer exclusively a means of attraction, but a *conditio sine qua non* of virility (von Krafft-Ebing).

The foregoing *résumé* includes all the essential forms of paræsthesia sexualis in accordance with the classification of von Krafft-Ebing, with their various distinctive features, and suffices for this work and the following chapters, the purpose of which is to modify and enlarge this theory in some particulars.

CHAPTER VIII.

HISTORY OF THE DEVELOPMENT OF CONTRARY SEXUAL FEELING AMONG THE ANCIENTS.

In order to form a judgment concerning contrary sexual feeling,—that is, with reference to prognosis and therapy,—its etiology is of the utmost importance. The causes and the conditions of development of this pathological phenomenon are to be studied not only in the individual, but it is of the highest scientific interest to understand the influences which, in the history of peoples, caused and favored this perverse activity of the sexual instinct. For we find love between persons of the same sex in all times and among all peoples.

Age and Extent of Sexual Inversion.—In ancient times Asia was looked upon as the land of origin of pederasty. From here it spread westward. The most ancient historical sources give evidence of the existence of the vice in question. But the first discoverers of America found the vice among the aborigines. Thus, it was generally spread throughout the inhabitants of Panama;[1] in northern Mexico marriages took place between men, and those who were dressed as women were forbidden to bear arms. Travelers in North America[2] found among the aborigines men, attired like women, doing feminine household duties. According to Mantegazza, pederasty, mostly in the form of male prostitution, is spread among the natives of Alaska, Darien, the Aleutians, Madagascar, etc.; and, according to Hammond,[3] it is made use of for religious purposes by the Pueblo Indians of New Mexico. On the island of Ramrih,[4] on the other hand, women acted like men in order to stand at the head of affairs, and attached themselves to other women, with whom they lived as man and wife.

[1] Mantegazza, Anthropologisch. culturhistorische Studien über die Geschlechtsverhältnisse der Menschen, Jena, Costenoble, p. 118.

[2] This vice is so little the product of excessive civilization that it has been met in North America. Comp. Virey, Historie naturelle du genre humain, Paris, 1824, vol. i, p. 273.

[3] Hammond, *op. cit.*

[4] Sitzung der Berl. Psychol. Ges. vom. 15 Okt., 1868.

In his work, "Conträre Sexualempfindung" (Berlin, Kornfeld, 1891), Dr. Moll gives, in its essential points, a *résumé* of the history of contrary sexual instinct, which, beginning with the Bible and Greek mythology, he traces through ancient literature (Greece and Rome) to the cloister-life of the middle ages, and thence to modern times, giving interesting facts concerning historical personages who are under the suspicion of uranism (*e.g.*, Rudolf of Hapsburg, Michael Angelo, Shakespeare, Heinrich von Kleist, and others.). To avoid unnecessary repetition, I may permit this reference to suffice, and allow the reader to peruse for himself the exceedingly instructive historical portion of that work. The following statements, however, come in place here, since they are either deviations from the opinions of that writer or additions to his material.

Historical Conditions of Development.—History and folk-lore show that there has been spontaneous and, to a certain extent, idiopathic occurrence of male-love[1] and pederasty among various peoples and at various times, where there has been no possibility of a spread of the disease by means of communication between the natives of various regions of the globe. Uranism occurs as the product of a special development, for which the conditioning causes must be given in the relation of the sexes and, perhaps, too, in climatic conditions.

Most authors, especially Moll, state that the most important etiological influence in contrary sexual instinct is degeneration of the central nervous system, as that is understood with reference to neurotic or psychical taint. To be sure, it cannot be gainsaid that the majority of contrary sexual individuals are, at the same time, neuropathic. But this explanation does not show why the degeneration must be expressed in this kind of sexual perversion. Moreover, it is quite possible that the neuropathy occurs as a result of the feminine *rôle*. Finally, it seems to me by no means demonstrated that savage peoples in which homo-sexuality occurs manifested primarily a neuropathic disposition, upon which this vice was secondarily engrafted; it

[1] Contrary sexual instinct in women never attained such practical importance, socially or medically, as it has in men. Therefore, in this book, it receives but subsidiary treatment.

is necessary to show other signs of degeneration in them. And why must just this single deviation of the sexual instinct occur primarily as a sign of a neuropathic or psychopathic state? Why not, with the same right, include all the other sexual vices which the lively fancy of sensual Asiatics created, deified in the cult of Lingam and Phallus, and worshiped in the most licentious way in orgies in honor of Astarte (or Mylitta)? To make hereditary disposition alone or principally account for the origin of contrary sexual instinct is to push back the riddle and regard it as atavistic, but not to solve it. Then, the question is: What circumstances first caused the savage to seek gratification of his instinct in intercourse with his own sex? For, as with other hereditary peculiarities, it is certain that in the developmental history of man pederasty must once have been primarily acquired.

In proportion as the natural purpose of coitus, procreation, gave place to lustful lasciviousness, as we again and again find in folk-lore that it has, the usual manner of gratification lost the stimulus of novelty. The effort to bring about variations of the simple act of coitus called to life the theories of an unnatural Venus (Venus illegitima), in which, according to Rosenbaum,[1] every trace of the real purpose of the genitals finally disappeared. Wherever the impressionability of the genital centres has become weakened or dulled by sexual excess, we see that the human imagination seeks new and more intense means of stimulation in order to bring about the desired gratification.[2] Thus, for example, to-day there is scarcely a doubt that tribadism is most frequently encountered among prostitutes, and that, too, without the necessity of any previous predisposition. Moll cannot account for the transition to the same sex; still, the experiences in prisons show that unsatisfied sexual desire resorts, *faute de mieux*, to immediate compan-

[1] Ploss (Das Weib, Leipzig, 1891, p. 315) also shows that the lower a people is, the more disgusting the expression of their lust and animal sensuality becomes. Many primitive peoples made use of excessive means of excitation in order to incite feminine lust. As Cubary states, "On the island of Ponape, some men go so far as to place a piece of fish in the wife's vulva, so that they may gradually eat it out. This revolting act is continued until the wife begins to urinate, and then coitus is performed."

[2] Rosenbaum, Geschichte der Lustseuche, 1888, p. 119.

ions, and that mutual onanism and pederasty are frequently met in penitentiaries among relatives of the same sex. Here, at least, the original of primary homo-sexual pederasty forms the transition to pedicatio mulierum. This view also finds support in historical sources, which, however, are anything but abundant.

Pederasty as a Cause of Homo-sexuality and Castration. —In Asia, as in Italy and Spain, the female genitals, like the whole body, are greatly relaxed.[1] The sphincter ani is much more powerful than the constrictor cunni. And, with respect to this, we may consider Forberg's[2] statement: "Et voluptas quidem pædiconis facile intelligitur, cum omnis voluptas mentulæ pendeat ex frictione." The following passage from Paul's Epistle to the Romans (chap. i: 24, 26, 27) also indicates that pædicatio mulierum preceded actual pederasty: "Wherefore God also gave them up to uncleanness, through the lusts of their own hearts, to dishonor their own bodies between themselves: . . . for even their women did change the natural use into that which is against nature: And likewise also the men, leaving the natural use of the woman, burned in their lust one toward another; men with men working that which is unseemly."

After the unusual manner of obtaining gratification with women had once been exhausted, the feminine appearance of boyhood gave a new charm. Therefore, still to-day, as formerly, active pederasts prefer, as a rule, beautiful boys of an age when the masculine characteristics (beard, voice, etc.) have not yet become pronounced. "They have the same glance, the same delicacy of skin and form, the same breath of innocence as the maiden" (Max Dessoir). Next, only feminine charms in the male person became attractive, which, on account of the peculiar combination, were especially enticing to persons with perverse inclinations. In this way pederasty with males was learned,

[1] Comp. Martialis, lib. xi, Epigrams 22 and 79.

[2] Antonii Panormitæ Hermaphroditus, ed. F. C. Forberg. The apophoreta of the editor treats of "De figuris veneris," "De fututione," "De pædicatione," "De irrumando," "De masturbando," "De cunnilingis," "De tribadibus," "De coitu cum brutis," "De spintris." Comp., also, Rosenbaum, *loc. cit.*, p. 121.

and from it, later, arose castration and gynandry. The degenerative transformation of the male character while in the stage of development (puberty) first occurred as a result of adaptation to the necessary *rôle*. Therefore, the sexual instinct became transformed secondarily as a result of artificial cultivation. Effemination is, therefore, originally a phenomenon resulting from pederasty, and then, where, in spite of the sexual transformation, procreation took place, it may have exercised hereditary influence. With this view, the following citation from Lucian (Amor, chaps. xx, xxi) is of interest in connection with the history of pederasty:—

"Gradually descending from the height of morality into the abyss of sensuality, strange and unusual manners of gratification were practiced. Debauchery, which attacked everything, transgressed even the laws of nature, *and a man was taken for a woman.* Either animal passion was satisfied by force or cunning was used to obtain consent. One of the same sex thus placed himself in the power of another. But to each the sight of his own sex in his companion did not cause him to be ashamed of what he did or permitted. The boldness of some, in their despotic manner of life, went so far that they robbed themselves of masculinity with the knife. They reached the goal of their sensual desires only when they, as men, had removed their manhood. But the unfortunates, in remaining boys longer, are no longer men,—an equivocal expression of a double nature; for they know not to what they were born nor what they are," etc. Gradually, in Asia, pederasty became embodied in the worship of Venus.

According to the excellent descriptions by Rosenbaum, the expressions *εὐνοῦχοι* and *ἀνδρόγυνοι* at first signified nothing but "Kinäden" or "Pathici,"—*i.e.*, persons who sacrificed themselves in the temple in honor of the deity.[1] Thus is explained the teaching of the priests of Cybele, who emasculated themselves, it is said, in honor of the deity.

[1] Later, in Rome, the term "exoleti" (castrated) was used in the same sense. Comp. Aristotle, Polit, v, 8, 9. This fact seems to be little known. Thus, Mantegazza, who has written a long chapter upon sexual mutilation, does not mention it. Comp. Anthropol. Kult.-St., p. 132.

According to Hellicanus,[1] the practice of emasculating boys was derived from the Babylonians. The origin of the custom is attributed to Semiramis.[2] Still, as Steut[3] believes, it is probably much more ancient. Herodotus states (iii, 92) that the Babylonians were required to send the Persian kings each year five hundred eunuchs as tribute. At any rate, the traffic in eunuchs was very wide-spread. Tavernier relates (according to Steut, p. 8) that in the kingdom of Bootan twenty thousand eunuchs were made every year to be sold to other nations. Philo[4] also holds to the opinion that castration was principally a result of pederasty. "Some had such esteem for youthful beauty that they (the androgynists) desired complete transformation into females, amputated the penis, dressed themselves in purple garments, etc." Only at a later period was castration practiced after maturity had been attained, so that eunuchs could still the erotic desires of women without the possibility of producing pregnancy (Rosenbaum).

Eunuchism.—Steut, who, in his work, "Chinese Eunuchs," describes in detail the character, habits, duties, and preparation of the Chinese eunuchs, does not once mention their sexual intercourse with men; but he gives interesting explanations of the inner and outer transformations, in the sense of effemination, which occur in the eunuchs. He says (p. 38): "All eunuchs lose their natural voice; those that have been subjected to the operation in childhood have a voice which can scarcely be distinguished from the voice of a young woman, while those so treated after reaching maturity speak in a kind of broken falsetto. In general, the Chinese are not troubled with an abundance of hair, but the eunuchs are devoid of even the slightest trace of hair on the face. If one be possessed of a beard at the time of his castration, the hair gradually falls out, and, finally, the face is as smooth as a billiard-ball. It is scarcely necessary to mention that on the face of those castrated in childhood hair of no kind ever appears." When operated

[1] Donat. Terent. Eunuch., I, 2, 87.
[2] Marcell, xiv, 6.
[3] Steut, Chinesische Eunuchen (Leipzig, Schulze), p. 6.
[4] Philo, Opera, ed. Mangeg., II, p. 465.

upon early, eunuchs often become corpulent, but their flesh is soft and relaxed. With advancing years they become thinner and terribly wrinkled. Castration seems to rob them of all that is manly; they grow old rapidly, and at the age of 40 look to be 60 years old.

In the performance of certain natural acts, eunuchs are very modest; and they will endure great inconvenience until they gain an opportunity to perform them unobserved. "This peculiarity is the more to be praised, since usually the Chinese are not in the least embarrassed when observed under such circumstances." They are not at all blood-thirsty, but much rather the opposite. Harmless and affectionate, they love all sorts of amusement. The slightest thing moves them to tears. They are loving to women and children, and exceedingly kind to the little dog with which almost every one is provided. In spite of their timorousness, they are irritable and excitable and cross, like women, but they are easily appeased; a trifle which another person would scarcely notice may throw them into an ungoverned rage. In general, the appearance of eunuchs may be called repulsive; yet young eunuchs are often very pretty and feminine. In fact, they might be taken for young women in male attire. As they grow older, one cannot help thinking that they resemble old women that have forgotten their sex and age and masquerade in the garments of the opposite sex. Too, they may be recognized at a distance by their gait. They take short steps, and hold the legs close together. In this way an independent observer describes the complete effemination of the eunuchs resulting from castration, without recognizing the original object,—*i.e.*, the cultivation of the female type in the male body for the purpose of pederasty.

Another reason for the occurrence of pederasty may be found in a deficiency in the number of women and in difficulties in the performance of coitus. Mantegazza[1] seems to have stated the truth when he says: "The errors of physical love all originate in two sources,—either in the difficulty or impossibility of gratifying it in the natural way, or in the desire

[1] Mantegazza, *loc. cit.*, p. 106.

to experience a new pleasure. That, in simple words, is the psychology of sexual vice, from Sodom to Lesbos, from Babylon to the island of Capri."

The Historical Origin of Uranism in Europe.—The Jews seem to have become acquainted with boy-love in Syria.[1] According to ancient authorities, the Persians,[2] the Celts,[3] and even the Germans[4] were acquainted with it. Pederasty, as already mentioned, was most practiced in ancient Babylon, in Sodom,[5] and by the inhabitants of Tyre.[6] From Asia uranism was spread by the Phœnicians or Lydians[7] (Welcher) first to Crete, and from there over all Greece.[8] According to Suidas,[9] the Italians were again the discoverers of boy-love, which was practiced in the most vicious manner, especially by the Etruscans, Samites, and Messipians. In the year 433[10] after the founding of Rome, this vice was practiced there. In the year 585 (B.C. 169), on the other hand, the Lex scantinia[11] was promulgated, which is indicative of the great extent of pederasty.

During the Empire, as is known, this vice took on an unrestrained character, and the horrible scenes under Nero, Tiberius, and Caligula mock all description.[12]

Greek Boy-Love.—The boy-love of ancient Greece is of the greatest historical significance. And, in our opinion, in the development and training of the Greeks, even during its period of greatest prevalence, this vice could never have played so important a *rôle*, even though, as with other people, it had been manifested only in coarse sensual enjoyment. The idealizing faculty of the Greeks was capable of ennobling a phenomenon which had its origin in common sensuality, and of transforming

it into an incentive to progress both in the individual and the masses, and to-day it stands unique in the history of that people. Like the idealized worship of Venus, uranism took on a spiritual form; in Athens "*pederasty*" became "*pedophily.*" The reckless violation of boys and honorable boy-love are to be strictly distinguished from each other in judging the male relations which existed in ancient Greece. Pederasty was not approved by the Greeks; on the contrary, originally, in Athens and Sparta, it was punished with dishonor, exile, and death.[1]

Still, the basis of the relations between youths and men remained sensual. Spiritual communion, pleasure in physical beauty, affection more intense than pure friendship, and close ties of fraternity (associations), though sensual enjoyment could never be more than that of the eyes, were the original features of pedophily. Nowhere do we find such a purification and idealization of this institution in education, philosophy, poetry, and art as among the Greeks; nowhere a similar respect for it on the part of the State and laws. Too, this fact is not altered by the circumstance that the limits of moderation—the bridling of sensual passion—set by individuals were also exceeded,—a condition which led to legal regulation of these relations.

Above all, according to historical evidence, pederasty, as long as it maintained its independent position, seems to have been regarded as a disgraceful vice by the Greeks (Sparta and Athens).[2] On the other hand, it cannot be denied that, in some Grecian States, boy-love never became elevated above the state of unnatural vice; for example, in Crete (kidnapping of boys and pederasty), Elis, and Bœotia,[3] and also in Phocis, Thessaly, Lesbos, Chalcis (χαλκιδίζειν = παιδεραστεῖν), etc.[4] But in the Ionic cities boy-love was absolutely forbidden.[5]

From the way in which boy-love first manifested itself in Athens and Sparta,—when it was most intimately connected,

during the golden age of Greece, with the greatest works of art and science, *and that without endangering in any way masculine strength and activity* displayed in numerous wars and in the games,—it is clear that this was not yet a degenerative transformation of the man into a woman (homo-sexuality) upon the basis of neuropathic disposition, even though sensual passion, frequently enough, may have surpassed the bounds of morality and law. Rather, the conditions of Greece give evidence that there, as everywhere, effemination was the direct result of pederasty. During the golden age of Athens pederasty and homo-sexuality were already quite well known and wide-spread; during the period of decadence and political dependence of Greece, pedophily lost its significance and male-love was known only in its vicious form. The vice of male prostitution was surpassed only by that of females during the period of decay.

Many authors, Moll among them, express the opinion that the prevalence of male-love is in inverse proportion to the esteem in which woman is held; and numerous examples in support of this view may be cited from the history of Asiatic peoples. It is certain that this factor played an important part in the peculiar development of Greek boy-love. The isolation of the women; their exclusion from the benefits of education and interest in the welfare of the nation, and from participation in the later education of children; the limitation of their activities to the simplest household duties; and their exclusion from the influence of improving and elevating social intercourse, rendered them incapable of taking part in the intellectual life of the men. The education of boys lay in the hands of the State; the relation between teacher and pupil necessarily took the place of paternal influence; the lover was the second father of the beloved.

Pedophily reached its highest perfection where gymnastics was most assiduously cultivated in the gymnasia and palesta.[1] The sight of the nude beauty of the youthful body in the highest state of strength and activity gave pleasure to the artistic sense of the Greeks and affected sensuality. This feeling was

[1] Plato, Legg, i, 636b.

deepened by the intellectual element which was fostered by education. Each lover necessarily became an example and guide for the beloved one in all that was beautiful and good. In Athens, the seat of philosophical boy-love, there were no public educational institutions, and all scientific and professional education was given by some approved elderly man to youths who became attached to him. This relation was brought about solely by inclination; for no honorarium was offered for such instruction[1]; and it took the place of our higher education. Finally, the necessity for the exercise of political influence by means of fraternities (associations) favored the development of boy-love. Indeed, in Sparta the members of the royal families were the beloved in boyhood and lovers when matured. In a sensual sense, the restraint between lovers was compared with that between parents and children, or between children of the same family. In Sparta, for example, the lover represented[2] the beloved in the popular assemblies, and kept by his side in battle; and there were instances of faithfulness unto death. The influence of the lover, in its effect upon the development of manly virtue in the beloved, was so great that not infrequently the lover was punished for the beloved. The mixture of a sexual element in these relations, originally so pure, induced a warmth of feeling which otherwise exists only between man and woman; the efforts to win favor led to the most violent jealousy; the delicate playfulness and the ways in which the lover expressed his feeling call to mind contrary sexual feeling, —spending the night at the door of the beloved; serenades; carving the beloved name on walls, on trees, and doors;[3] swinging garlands on the house of the beloved; presents of vases[4] on which were inscribed confessions of love.

This coquettish playfulness also expressed itself in poetry. The lyric poets, Pindar, Alcæus, Anacreon, and Ibycus sang of boy-love. Epic, elegiac, and bucolic poetry, and, later, the drama, each contributed its share. Even a woman, the Syci-

onian poetess, Praxilla,[1] sang of male-love. The Greek gods and heroes glorified the fraternity of arms and the relations of the lovers.

Of the more familiar examples may be mentioned Zeus and Ganymede, Pelops and Poseidon, Achilles and Patrocles, Orestes and Pylades, Heracles and Hylas, Apollo and Admet; Adonis is beloved by Dionysius, Theseus by Minas, etc.

The most illustrious men Greece produced stood in the closest relation to the peculiar institution of boy-love. It will suffice here to allude to the following examples, which by their influence attained historical significance, and, in a measure, became the basis of political movements.

Solon[2] is reputed to have loved Pisistratus; Pisistratus,[3] Charmus; Charmus, Hippias, etc. The love of Harmodius[4] and Aristogeiton became the cause of the liberation of Athens from the tyrants (Aristogeiton's jealousy of the tyrant Hippias).

Aristides and Themistocles both sought the favor of Stesileos, which became the cause of their rivalry. The three great tragic poets, Æscylus, Sophocles, and Euripides, glorified boy-love both in poetry and life, as did Agathon and Aristophanes. The greatest sculptor of Athens, Phidias, loved Agoracritus and Pautarches.[5]

Of the famous statesmen who were devotees of boy-love, there were Alcibiades, Æschines, Timarch, Demosthenes, and Demetrius. Likewise, the most celebrated philosophers were given to it,—Socrates, Parmenides,[6] Plato, Dion, Phedrus, Alexis. Zeno,[7] the founder of the Stoa, seldom or never had intercourse with women, but only with beautiful boys, which must be regarded as a sign of beginning homo-sexuality. The Stoics were often reproached with having followed the example of their founder with only too much zeal.

Impure Male-Love in Greece.—The fact that Socrates[1] sought to elevate the wide-spread relation of pedophily and give it a moral direction illustrates clearly enough the frequent occurrence of pederasty during his time. On the contrary, in his philosophy, Zeno[2] goes so far as to place unnatural intercourse of boys and men on a level with natural sexual congress. It is no wonder that the adherents of immoral boy-love have ever sought to cover themselves with the mantle of Socratic and Stoic philosophy. This is not the place to determine to what extent, in individual cases, pedophily was abused for sexual purposes. There was no want, in comedy (Aristophanes) and in literary productions, of attacks, denunciations, formal complaints, and punishments directed against this form of indulgence; the whole of Greek literature gives clear evidence that, during the period of highest morality, immoral boy-love was regarded as a disgrace.

Solon showed his respect for boy-love[3] by the enactment of a law which denied it to slaves, and thus elevated it to be a prerogative only of free individuals. If, however, an Attic citizen voluntarily prostituted his person[4] for gain, the law punished him with life-long loss of all the rights of citizenship. Still severer punishments were inflicted upon those who committed the crime with minors. Between sunset and sunrise the grammar- and wrestling- schools were closed by law,[5] in order that, during the darkness, there might be no opportunity for the seduction of boys. Likewise, the children-festivals and attendance at the gymnasia were carefully regulated. On the other hand, barber-shops, ointment-shops, drug-stores, and bath-houses seem to have been the places of show where men in love dallied. The good old morality and education gradually gave place to effeminate practices, and male-love, previously regarded only as an error and indulged in secret, became more and more shamelessly prevalent. With this process of development, in ancient Greece, the history of contrary sexual feeling reached the stage where, on the foundation of base immorality and

previous pederasty, homo-sexuality and effemination began to manifest themselves, owing to attempts to approach the required female sexual *rôle.*

Youths, as Aristophanes[1] says, sold their bodies for money, and boy-love became a means of livelihood. The pathici began to attract the attention of lovers by means of low, coquettish arts, and did not despise those of the toilet,—*καλλωπίζεσθαι.* If possible, they deprived their persons of every mark of masculinity; they gave themselves to vile uses in secluded spots, in private houses, on the walls, etc. Handsome young slaves were forced[2] to yield their bodies to their masters for gain, and live in actual houses of prostitution. The extent to which the puer venalis was characterized by his external appearance is shown by the Greek proverb: "It is easier to take five elephants under the arm than to conceal a pathicus."[3] Then male prostitution became a trade[4] that was taxed. The Senate of the Five Hundred farmed out this tax yearly to a man who collected it. Thus we see how the originally pure boy-love found its end in prostitution and effemination.

Θήλεια νοῦσος.—The following facts present us with the important proof, from historical sources, that the theory of contrary sexual instinct, as to-day set forth by von Krafft-Ebing, for example, was known to the ancients in all its essential points, both pathological and moral. Indeed, Rosenbaum,[5] by a careful investigation of various statements by credible authors, has shown that, for designating this class of men, the Greeks had a term which in meaning is identical with what Westphal named "contrary sexual feeling." Herodotus first applied this term to the Scythians, who learned pederasty in Asia (Ascalon in Syria), returned as pathici, and widely developed the vice in their native land. He says: "The goddess Venus Urania let *θήλειαν νοῦσον* fall upon them,—*i.e.*, *the passion or disease which transformed them into women.*" Among a people like the Greeks, whose intellectual development was of the highest order, male sexual intercourse was practiced only by a certain percentage of the

people; on the other hand, with a race of small resistive force, like the Scythians, whose sexual character was never markedly developed, the whole transformation to the feminine type, both mentally and physically, took place much more readily in general, and thus became more striking to the foreign observer.

Spontaneous Origin and Cultivation of the Feminine Type in the Male.—Hippocrates referred this Scythian disease to constant riding, which induced frequent pollutions. Too, it was thought that nomadic life contributed to this, for the Scythians were not accompanied by their wives on their expeditions.[1] Many authors, Hammond[2] included, are of the opinion that excessive riding induces atrophy of the testes and consequent impotence. Those affected with the disease lost the physical and mental peculiarities of the male sex; impotence occurred, the beard disappeared, and the penis and testes atrophied. "Finally, the mind becomes so much affected that these individuals look upon themselves as women, dress like women, and assume the habits and pursuits of the female sex" (Hammond).

Too, among the modern descendants of the Scythians, the inhabitants of the Caucasus, impotence is said to be of frequent occurrence. Constant compression of the vesiculæ seminales and the prostate induces frequent pollutions, irritable weakness, and, as a final consequence, impotence.[3]

Two cases of Hammond's[4] are classical examples of the possibility of artificial transformation of a man into a woman; and they are briefly given here because they are of fundamental importance in the consideration of the origin of contrary sexual instinct. According to Hammond's report, among the Pueblo Indians of New Mexico it is customary to induce impotence in one native in each village and use him for pederastic purposes. This person is called a mujerado (mujeriego = changed into a woman). The first case was that of an individual, aged 35, dressed as a woman; the breasts were unusally developed and looked like those of a pregnant woman. He told Hammond

[1] Sprengel, Apologie des Hippocrates, Leipzig, 1792, Part II, p. 610.
[2] Hammond, *loc. cit.*, p. 106.
[3] Lallemand, Des pertes séminales, Paris, 1836, Part I, p. 581.
[4] Hammond, *loc. cit.*, p. 111 *et seq.*

that he had nursed several children whose mothers had died, and that he was able to furnish them much milk from his breasts. No pubic hair; penis much reduced in size; the scrotum contained the remnants of testicles; slight varicocele. He had been a mujerado for seven years; but, up to the beginning of that period, he had possessed all the sexual attributes of masculinity. At first his testicles became smaller, and with their atrophy he lost sexual desire and all inclination for masculine pursuits, and, therefore, sought female society. At first his penis retained its normal size. After the loss of erectile power the member soon became atrophic. He said that before he became a mujerado he had a large penis and testicles of the size of eggs,—a statement confirmed by his companion. His voice was high and thin.

The second mujerado examined by Hammond had atrophied penis and testicles, "which apparently consisted of connective tissue." Pubic region free from hair; breasts not especially developed; limbs full and round; hair only on the head; voice high and weak. His nude appearance was more that of a woman than that of a man. He was 36 or 37 years old.

As in the religious orgies of the ancients (priests of Cybele), among those of this race of Indians the mujerado is indispensable for the performance of the passive *rôle* in pederastic practices. For the production of a mujerado usually one of the most powerful men is chosen, and masturbation is practiced on him many times daily. At the same time he must ride constantly, and that without a saddle. Irritable weakness and diminution of the nutrition of the genitals set in. Then, in spite of orgasm, ejaculation becomes impossible, and finally it is no longer possible to induce orgasm. Then atrophic shrinking of the penis and testicles occurs. Simultaneously the man's courage disappears; he becomes timorous; all his influence and responsibility are removed, and he bears himself like the women of his race. Besides this, he tries to divest himself of all masculine characteristics.

The victim of the *νοῦσος θήλεια*, the Scythian disease, differs from the mujerado only in that what took place in the

former as the accidental result of certain customs and habits was artificially brought about in the latter for a distinct purpose. After this diversion, important for an understanding of contrary sexual instinct, we may return to the ancients.

Views of Some Ancient Writers Concerning the Pathicus. —The historical facts of the development of pederasty among the Greeks, as among the Scythians, confirm our view, previously expressed, that its artificial introduction among them, and the forcible performance of pederasty on boys, form the origin of contrary sexual instinct and effemination; and that then, through its effects, seriously injure the manly virtues of the people,—a process appropriately called "eviration." The transformation of the masculine type into the feminine, as a result of pederasty, was commonly looked upon as the revenge of outraged Venus.[1]

It was known to the ancients that the vice of pederasts was capable of transmission hereditarily to the members of a family in the form of disposition,—a confirmation of von Krafft-Ebing's theory of heredity. However, the same form of perversion did not necessarily appear. The case of Heliades,[2] who had been punished by Venus in the manner mentioned, had this reputation. Thus the orator Lysias[3] says of the family of Alcibiades: "The majority of its members had been prostitutes." Indeed, there was even a view that the pathici might be born with a predisposition to the vice,—an opinion which Parmenides[4] (509) expressed. While the author mentioned looked upon the basis of the disorder as mental, other writers, as Aristotle,[5] regarded the vice as a disease of the rectum. According to Aristotle, the seminal vessels conveyed the semen not to the rectum, but to the anus, and there excited pleasure and libido. Those affected in this way were, in his opinion, congenital pathici, from whom he distinguished those produced by habit (πεφυκότες and ἐξ ἔθους). Here we see the theory of Mantegazza foreshadowed, who looks upon the cause of a certain form of contrary sexual instinct as

[1] Euripides, Hippolyt, 5.
[2] Tragedy, Hippolyt, 124; and Lucian, Amores, c, 2.

[4] Cælius Aurelianus, de morb. acut. et chron., lib. vii.
[5] Aristotle, Problem iv, 26.

an abnormal distribution of nerves (to the rectum). Statements concerning the physiognomy and other marks of androgynes and pederasts are numerous; which, aside from the external appearances given them by the race and the customs of the times, in all essential features are comparable with those peculiar to the sexual perverts of our day.

Polemon[1] calls attention to the enticing, lustful glance of the androgyn, and says: "The hips are in constant motion. He speaks in a voice that is high and shrill, forced and tremulous."

Dio Chrysostom[2] thought he could detect pederasts by their sneeze. He says: "Thus sneezing revealed a man's real character, and in spite of all else would betray him." Rosenbaum thinks that during the act of sneezing the pederast attempted to control the sphincter ani, since it was weakened or destroyed, and could no longer perform its function. "Even with a normal sphincter it is often hardly possible, during the act of sneezing, to restrain the expulsion of gas or even fluid fæces."[3]

Lucian satirizes the customs and laws of the pederasts; "how they care for their persons, and pull out their hair; how pederasty is practiced, passively and actively"; their features, gait, voice; the bowed head; the powder, mastic, paint, with which they adorned themselves, etc.

According to Martial,[4] "these male prostitutes had their beards shaved as closely as possible, and the hair removed not only from about the anus, but from the whole body as well, in order to simulate the female person." They dressed entirely like women.

One of the most noted pederasts of Athens was Cleisthenes. Aristophanes made him the object of his satire. Later his name became a designation for pederasts.

According to the evidence adduced by Rosenbaum,[5] outraged nature revenged herself on the pathicus by assisting him

[1] Polemon, Physiognom., lib. ii, 9, 1, c, p. 290.
[2] Dio Chrysostomus, Tarsica, i, p. 410.

[4] Martial, lib. vii, epigram, 57.
[5] Rosenbaum, *loc. cit.*, p. 179.

in his efforts. "Through distension of the anus the nates grow broader below, the intermediate space wider, so that the hips assume more the form of those of a woman; and the pelvis itself seems to widen. The thighs change their direction and the knees turn inward more and more; in short, the whole inferior half of the body takes on the feminine type. The mind follows the body; the character becomes feminine. The pathicus detests coitus with women, and does not marry as long as he can satisfy his lust. When increasing years deny him the ability to satisfy his desires, nature at last has denied him the power of procreation; the genitals refuse to perform their functions" (shrinkage from disuse, and paralytic impotence).

But psychical hermaphroditism—a transitional stage in the process of effemination—was also known to the ancients. Alcibiades held intercourse with both sexes; Dionysius practiced normal coitus and passive pederasty.[1] Therefore, the latter was called *ἀνδρογυνος*. While for the passive party in pederasty, the pathicus, there was an inclination to find an excuse in regarding the phenomenon as a pathological result of artificial cultivation,—as a person suffering with a *νόσος* (disease), *ἀνάνδρια*,—for the active party there was no excuse. He was regarded as a debauchee "who destroyed the virtues of manhood most useful in war and peace; who in their place substituted in the mind the *νοῦσος θήλεια* and created androgynes; and who, destroying manly virtues, and giving them the peculiarities and characteristics of an object of love, injured the lover in the most precious things of life,—body, soul, and possessions."[2]

The passion to become a woman—evidenced by all authorities—is everywhere manifest later in history than the practice of pederastic acts with boys and men, which, as a rule, are at first enforced. The spread of this perverse activity of the sexual instinct may therefore be regarded as the cause of the congenital disposition to play the *rôle* of a woman and become a pathicus. For the androgynes (psychical hermaphrodites) allow themselves to be used as women, and, besides, beget

[1] Lucian, De dea Syra, c. xvi.

[2] Philo, De vita contemplativa, p. 480, cited by Rosenbaum, *loc. cit.*

children; they do not, like the pathicus, need to suffer with *νοῦσος θήλεια*, but they may, for the sake of gain, prostitute themselves.

One of the best and most complete confirmations of the correctness of the foregoing views which throws a clear light upon the etiology of contrary sexual instinct among the masses is Philo's description of the unrestrained lust and vice of the Sodomites. "Not only did those taken with a passion for women dishonor the marriage-bed of others, but men even approached men; pederasts of the same sex were not ashamed to consort with the pathicus; expending useless seed, they despised the begetting of children. Disgrace was without effect upon those controlled by so powerful a passion. Later, those born as men accustomed themselves to play the *rôle* of women, and took to themselves the *νοῦσος θήλεια* as a vice against which it was vain to struggle. For not only the body, as a result of feminine conduct and manner of life, became feminine, but the mind as well was deprived of all male characteristics, and they destroyed, as far as they could, all masculinity." In another place Philo[1] speaks of those to whom the law-giver refused permission to frequent holy precincts: "He kept all unworthy persons from visiting the temples; he began with the androgynes,—those who were affected with the *νοῦσος θήλεια*; who distorted nature's order and assumed the desires and appearance of lascivious women. He expelled those whose testicles were concealed and whose genitals had been removed with the thought of preserving a youthful appearance and changing the masculine to the feminine type," etc.

Résumé of Conclusions.—Pederasty, as the foregoing citations show, had its origin in Asia; it was adopted by the Greeks and changed into the form of ideal pedophily. This peculiar institution exerted great influence in the development of the Greek nation, on politics, art, and science. But, as soon as pedophily degenerated into violation of boys, the results of the vice were not wanting. It then was looked upon as the curse of Venus for a sin against nature. Thus there arose the class

[1] Philo, De sacrificantibus, p. 261.

called pathici. These individuals correspond with our ideas of those affected with contrary sexuality in our day. But the necessary artificial *rôle* of woman caused destruction of manly virtues. "Since a man of sound reason could not possibly allow himself to be used as a woman, when he does so he must be suffering with a disease,—a *νόσος* which changes him to a woman (*θήλεια*)" (Rosenbaum).

Later, matured men became pathici, which was the first clear indication that this phenomenon was pathological, and, at the same time, nervous and mental affections occurred simultaneously, or as its results (impotence, dementia, etc.). Still, among the Greeks effemination never became general, as among the Scythians. Castration originated, as we have seen, from the desire of the pathicus to preserve the characteristics of youth, and, as I surmise, to prevent the development of the secondary sexual peculiarities (voice, beard),—which, according to the Darwinian theory, make their appearance at the time of sexual maturity,—that the greatest possible resemblance to woman might be attained. Further, the foregoing detailed account shows that the whole theory of contrary sexuality, with reference to cultivation and heredity as well as to the forms in which it manifests itself,—psychical hermaphroditism and effemination in its various degrees,—was known to the ancients. Contrary sexual instinct, however, historically considered, appears as the direct result of pederasty; and the latter, in the primary practice of it, is nothing more than a vice practiced on youth or man (perhaps by force), instigated by immoral motives. Only habitual practice of pederasty leads to degeneration and changes the sexual character of the passive party to that of the female,—*i.e.*, it induces an inversion of sexual feeling, which, once developed to a fixed peculiarity, is in a condition to exercise further effects through heredity.

During the decadence of the Greeks and Romans and of other nations, neuropathy and increasing degeneration gave the broadest basis for the prevalence of all forms of immorality, and, therefore, during the periods of moral decadence of the people, contrary sexual instinct appeared everywhere in the form of

complete effemination and public prostitution, often in combination with symptoms of insanity (Cæsarian insanity), and it is difficult in individual cases to determine to what extent this perversion of the sexual instinct represents the product of the practice of degenerate customs (prostitution) or of hereditary predisposition. This difficulty also explains the views of authorities, by whom contrary sexual instinct is regarded as the symptom, as a rule, of a degeneration of the central nervous system.

In sexual development, however, the original course, as we have shown, is different: as a result of moral contagion or other external cause, a normal race may come to practice pederasty; this gives birth to contrary sexual instinct, and the latter then leads, through transformation of character, to degeneration of the individual. Therefore, only secondarily can contrary sexual instinct, on the basis of hereditary predisposition of the central nervous system, become developed as a symptom of this taint.

CHAPTER IX.

HEREDITY AND EDUCATION IN THEIR ETIOLOGICAL RELATIONS TO SEXUAL PERVERSIONS.

The Importance of the Part Played by Heredity in Anomalies of the Sexual Instinct.—Owing to the frequency of their occurrence and the legal enactments concerning coitus-like acts between men, in the literature of anomalies of the sexual instinct contrary sexual instinct takes the most important place. Too, there is hardly another error of the sexual appetite besides that of sexual inversion that is so powerful in transforming the whole personality and character. The question concerning the causes and origin of this perversion, as shown by the opinions given in the celebrated case of the Countess V.,[1] is still unsettled; and, in spite of the valuable review of the etiology which Moll[2] gives after a careful consideration of the majority of the authorities, the question still seems to us to be an open one.

The more the number of cases increases in which permanent therapeutic results have been obtained, the less seems, in our opinion, the influence of hereditary disposition in the origin of this anomaly. The discovery and exact estimation of the hereditary factor and of the extraneous influences that have had a baneful effect on development form the basis of diagnosis and prognosis. As von Krafft-Ebing justly remarks, it might be presumed *a priori* that it would be impossible to remove or modify a congenital perversion. Hence the hopeless prospect offered to such patients by text-books on psychiatry, such as Kräpelin's.[3] He says, "There can be no thought of treatment of an anomaly like this, which has developed with the development of the personality and has its origin deep within it." If, however, in cases which are presumably due to hereditary disposition, a complete transformation of the psycho-sexual

[1] Friedreich's Blätter f. ger. Med., 1891, Heft 1, pp. 32, 33.
[2] Moll, *loc. cit.*, p. 156 *et seq.*
[3] Psychiatrie, 2 Aufl., p. 576.

character is brought about, there can be but two ways in which to explain it: either, in comparison with extraneous influences, the effect of hereditary disposition has been overestimated, or it is actually possible to compensate by suggestion the dire effect of hereditary factors.

For therapeutic nihilism, of course, the theory of heredity is the most convenient, and individuals of contrary sexuality, who, in numerous instances, have no consciousness of their abnormality (contrary to Westphal's idea), find in it a very welcome excuse for their peculiarity: they believe that they are justified in obeying an impulse for the manifestations of which, owing to its hereditary origin, they regard themselves as irresponsible. And therein also lies the reason why such persons, happy in their peculiarity, will know nothing of treatment. Usually it is not the anomaly of their feeling that brings them to the physician, but fear of conflict with the law, and sexual hyperæsthesia which threatens to betray them; or symptoms of progressive neurasthenia, which interfere with occupation and daily life, are the causes which lead them to seek medical advice.

Hereditary Disposition in General.—If the character of the child were determined in the mother's womb, to continuously unfold in post-natal life, then the influence of education would be illusory. To speak with precision, hereditary inclinations are nothing but the results of the habits of our ancestors acquired through repeated and multiplied acts,—*i.e.*, capitalized activity that lives and constantly grows by its own activity. This fact is also demonstrated, as we have seen in the foregoing chapter, by the history of the origin of contrary sexual instinct. Every individual benefits or injures his descendants through the series of acts which make up his life, and which, through habit, become transformed in descendants into hereditary disposition. The mechanism of heredity and our intelligence continually exert a reciprocal influence on each other. Custom, through heredity, becomes racial instinct, in so far as in the past a repeated act, which at first is to a certain extent reflex in the process of adaptation to surroundings, may become typical for the future.

Racial morality is the condition of our progress and self-preservation; the object of education is to influence our moral and immoral hereditary tendencies,—*i.e.*, to seek to control our animal instincts. The education of centuries is fixed in the present generation by heredity, and yet we see the mighty power of racial instinct continuously working atavistically. Thus, the war-like tendencies manifested in duels to-day are but the natural result of the battles of our ancestors. Still, every hereditary disposition, to become active, requires its specific excitant; and from this may be estimated the enormous force which education acquires in the selection of the influences which affect us. Every organism passes through developmental or retrograde changes in accordance with the multitudinous adaptations made inevitable by the struggle for existence. Physical peculiarities (constitution, stoutness, longevity) are inheritable, like temperament, lack of power of resistance to external influences, and certain diseases and dispositions to disease. However, within the broad realm of inexorable law there is still left sufficient room for the exercise of human influences. Pseudo-heredity depending upon the imitative tendency of children must also be taken into account. In large measure inheritance is something possible, but by no means certain. Defect in the father may be compensated by corresponding perfection in the mother.

For the most part, as von Krafft-Ebing also allows in contrary sexual instinct, only the disposition to disease is inherited. Whether and to what extent it is developed largely depends upon later extraneous influences. The theory of atavism makes it probable that generations apparently free from it still bore the disposition undeveloped and transmitted it. Of all nervous and mental diseases, irritable weakness of the nervous system is most frequently transmitted as a neuropathic disposition, and it may develop into neurasthenia, and thus become the foundation of nervous diseases, according to the kind and intensity of the injurious influences of life. But, on the other hand, a proper mode of life may do much to prevent the development of the hereditary disposition, and thus, in a measure, compensate it.

Predisposition and Pathogenetic Excitants.—In constitu-

tional diseases, as in tuberculosis, only a predisposition to them is transmitted. It is very seldom, even though it be demonstrated, that tuberculosis is directly congenital. Thus, the reports of Brehmer's sanatorium (Wiesbaden, 1889), gathered from 506 cases of tuberculosis, show that the children of tuberculous parents are by no means always tuberculous, but, on the contrary, the grandchildren relatively often. As Dr. Krocker[1] reports, Dr. Sommerbrodt treated, in 1885, a lady who was pregnant for the fourth time, but subject to progressive tuberculosis. The first three children had died of more or less pronounced tuberculosis. By a rigid observance of all means to prevent infection, not only was there success in saving the life of the fourth child, born in December, 1886, and preventing infection, but the same means were successful in the case of the fifth. One child is now 3 and the other nearly 4 years old, and both are blooming and healthy.

There could be no clearer demonstration of the fact that with inherited disposition to a disease there must also be the specific pathogenetic excitant in order to produce the actual disease. The etiological factors of predisposition and exciting influence operate analogously in contrary sexual instinct.

Heredity and Exciting Causes in Mental Diseases.—Like the majority of psychoses, the heredity of contrary sexual instinct presents the picture of polymorphia. Only in one case (von Krafft-Ebing) was the father said to be affected in the same way. As a rule, only a neuropathic disposition, a slight degree of mental weakness, or (according to Koch) psychopathic inadequacy is congenital. Whether, on the basis of this hereditary lack of resistive power, contrary sexual instinct must necessarily develop as the hereditarily-conditioned product seems questionable. Moll[2] avoids the answer, when he says: "Why in the one case the degeneration expresses itself in epilepsy, and in the other as contrary sexual instinct, we are as little able to answer as the question why, in taking cold, one has catarrh and another rheumatism."

[1] Comp. Krocker, Krankheitsursachen und deren Bekämpfung, Paetel, Berlin, 1891.
[2] *Loc. cit.*, p. 162.

In his very instructive work on direct heredity,[1] E. Sioli differentiates a class of psychoses in which hereditary transmission is complete; the same kind of delusions, like instinctive impulses, and a like fatal tendency to suicide are manifested at a like period of life, under the influence of definite causes of a similar nature. We shall see, later, whether in literature cases of contrary sexual instinct are to be found which can be assigned to this class.

More important for us, however, is Sioli's collection of families in which ancestors and descendants were affected with mental diseases which were, in descendants, caused more by demonstrable extraneous influences the effect of which could be ascertained, than by inheritance. Only *new* and *additional* injurious influences, or subsidiary causes, induced a psychosis in those descendants that showed no demonstrable disposition, or in those that presented signs of degeneration and lessened power of resistance; and the form of the psychosis either corresponded with that in ancestors or was transformed. Such subsidiary causes are: puerperium, puerperal diseases, unjust punishment, illegal pregnancy, head-injuries, etc.

These exciting causes may, when sufficiently intense, determine the form of the disease; still, the number of such psychoses is much smaller than those essentially determined by heredity.

The literature of contrary sexual instinct, especially the autobiographies of urnings, leads us to think that hereditary disposition, as a rule, has been overestimated, to the detriment of exciting causes. The possibility of direct inheritance of contrary sexual instinct, which, in infrequent cases, may develop in spite of all training, cannot be gainsaid, though a convincing proof of it has not yet been given. On the other hand, it will be our object to ascertain what influence exciting causes, especially of a sexual nature, may exert in themselves on the origin of this perversion.

In order to estimate fully and differentiate the causal factors (hereditary disposition and education) in the origin of

[1] Archiv für Psychiatrie u. Nervenkrankheiten, Bd. xvi, Heft 1–3.

the perversions of the sexual instinct, it seems necessary to consider man's normal sexual development.

Physiology of the Development of the Sexual Instinct.—The procreative instinct, corresponding with anatomico-physiological processes, develops relatively late in man.

The functional development and growth of the generative organs stand in definite interrelation to the cerebral cortex, where sensations and ideas (impulses) arise. Actual puberty begins, in the female, at the age of 13; in the male, at the age of 15. Until this time is reached there is usually no knowledge of sexual matters. Under normal conditions, with the help of education and imitation, the mental type corresponding with the sex is developed, which *per se* does not depend upon the processes in the generative organs alone. In early years the individuals are sexually neuter,—a state which Max Dessoir calls "undifferentiated sexual feeling."

We can neither assume that there is innate knowledge of the difference of the sexes nor the possibility of the inheritance of ideas at all. In this sense, from a strict psychological stand-point, there is really no "congenital contrary sexual instinct."

Like all animals, man acquires the most through practice and experience. Like the sexual instinct, the instinct for food, in its first blind expressions, is an impulse the purpose of which is only gradually comprehended, in that, striving for fulfillment, it brings about external impressions. Sense-impressions are at first necessary for the expression of the instincts; according to Wundt,[1] they alone bring about sensation and feeling. The idea of the mother's breast is not innate in the nursling, but an ill-defined sense of hunger[2] causes movements which finally bring about the satisfaction of the need. "With the first satisfaction comes an indistinct idea of external objects which present themselves in the act, and thus, with the sense of hunger, at once the reproduction of the image of these impressions becomes asso-

[1] Physiologische Psychologie, 1887, p. 231.

[2] Why speak of a sense of hunger here at all? It cannot be a sense or feeling of any kind. The movements are purely reflex, arising from organic conditions which at first, at this period of life, can have no relation to sense or sensibility.—TRANS.

ciated with the desire." Thus are developed the simple instinctive acts.

The development of the sexual instinct is to be conceived in the same way. All ideas in relation to it are the product of experience, even though the impulse belong to the congenital instincts. According to Wundt, only the conditions necessary for the origin of definite general sensations, and for the association of definite movements with these sensations, can be congenital. Thus the sexual instinct, in its first indistinct expressions, is conscious of no definite purpose, and, at first, there are only purposeless feelings (physically produced by the generative organs) and emotions, which are called longings and impulses, and to which, through sensory impressions, the strengthening materials are supplied. The instinct induces movements which, to a certain extent, are reflex, and leads to instinctive acts. The disposition to these movements is congenital; it requires only excitation by external impressions to bring it to complete development.

A pronounced feeling in consciousness accompanies the instinctive act. After organic sensations have excited the attention of the individual, the presentiments are transformed into clear ideas by sensory perceptions. The sight of his own person or of animals may, at first, satisfy the vague impulses, and contains elements from which the imagination creates images corresponding with the feelings.

Among animals the instinctive expressions, in accordance with the accompanying individual sensory impressions, may go astray. "Darwin reports that young pointers point at other dogs, a thing that experienced pointers never do. The scent of game induces the irresistible impulse to point, though there is no idea of the game itself" (Wundt).

Pathological Determination of the Undifferentiated Sexual Feeling by External Impressions.—In the indefiniteness of the original impulses—the sexual instinct as well as the instinct for food—lies the nucleus of the various errors to which the individual is subject. If, owing to external circumstances and education, the object which nature has created to induce sexual

excitement does not present itself to gratify the longing for satisfaction, then the desire for satisfaction, *faute de mieux*, turns to the next best means, especially when there is ignorance of the sexual relations.

With premature awakening of the sexual appetite, as a rule, the opportunity for normal sexual intercourse is wanting. Therefore, onanism, brought about by tickling sensations in the glans and erections, is the most frequent result of this sexual precocity. The sense-impression which accompanies the first orgasm, brought about by tactile or psychical onanism, owing to the intensity of the feeling, is much deeper than the majority of impressions. The new perception, owing to the feelings accompanying it, is retained, no matter how great disparity there may be in it. According to the intensity of the feeling, the individual judges of the value of the perception for the Ego. The perceptions, both in content and in time, are so intensely associated in thought that thereafter the lustful feeling is regularly accompanied by the reproduced image of the external accompanying conditions. For the very reason that the individual has experienced nothing of this kind before, he will the more recklessly abandon himself to the most intense pleasurable emotion that nature affords, the less resistive power there is in his nervous system as a result of hereditary disposition. There is, too, no other possibility than that the onanistic act of an inexperienced individual will reproduce the impressions, once discovered and brought about by external stimuli, until experience offers other material. For "nihil est in intellectu, quod non prius fuerit in sensu."

Simultaneously, owing to the nature of the feeling, occurs the impulse to repeat this experience for the benefit of the Ego. Thus it is deepened and completed. The thoughts which have arisen from inadequate external excitation are joined with others, brought into definite relation with the Ego, and the sum of these states of emotion becomes an enduring object for the personality. Through the frequency of its reproduction the definite idea may finally become imperative, and at last in itself be sufficient to produce sexual excitement. In dreams it

accompanies pollutions, and becomes the starting-point of sexual perversions. Since, in the schools, education has brought about a strict separation of the sexes,[1] it is highly probable that the first sexual promptings—where there is complete ignorance of sexual matters—will be directed anywhere rather than toward the opposite sex. The longings and promptings of puberty are intensified at first in the presence of another person, no matter whether it be a girl, a friend, a much-loved relative, or an honored teacher (Mme. Lambercier and Rousseau). The person in whom there is the greatest confidence and with whom there is the closest sympathy, and who is at hand at the moments of excitement, will, according to sex and accompanying circumstances, play the determining part in the origin of the perversion.[2] The close boy-and-girl friendships that may be seen in every school, owing to sexual coloring, take on a sexual character, even though the individuals be unconscious of it; and, therefore, kissing, embraces, jealousy, tears, etc., are common events. Then all that is necessary is sexual hyperexcitation, or tickling sensations in the genitals induced by masturbatic frictions (with the thighs), to intensify this sensation to an unknown lustful feeling, and, with reference to the accompanying thoughts, the sexual instinct is determined,—*i.e.*, the impulse, seeking satisfaction, has become conscious of its object, even though it be erroneous.

The accompanying psychical manifestations of sexual excitation—that is, the sexual thoughts—always depend upon external impressions, the objects of which are brought into material relation to sexual feelings. The nature of the object determines by content the direction of the sexual impulse. The form of the perversion—*i.e.*, the object to which the perverted impulse has been directed—is determined by external circumstances, accidental events; and, in our opinion, as a rule, and

[1] Not true of the public schools of the United States.—TRANS.

[2] This statement seems too broad; if this be true, in the histories of cases of sexual perversion we should more frequently meet instances of incestuous tendencies; for often relatives stand in just the relation to the boy or girl indicated in the text. Compare the translator's article, "Incest," in "A System of Legal Medicine," vol. ii, E. B. Treat, N. Y. —TRANS.

in the majority of cases, it is not to be ascribed to natural tendency.

Hereditary Lack of Resistive Power, and Pathological Association.—In all forms of paræsthesia, without respect to whether it be contrary sexual instinct, algolagny, or fetichism, it seems to us that an essential factor is the fact of the origin of the perverse expression of the sexual instinct. It is entirely subsidiary that the same patient who, as a result of external circumstances, in one instance acquires contrary sexuality, in another might have become an algolagnist, or perverse in hetero-sexual intercourse. Natural disposition alone cannot explain why one becomes a lover of shoe-nails, another of ladies' eyes. The theory of pathological association which Binet[1] advocates, allowed in the case of fetichism, but not for contrary sexual instinct, would be inconsequential. The advocate of the theory of heredity is justified in laying the chief stress upon congenital predisposition, which supplies the basis for the development of any form of psycho-sexual disease, and, at the same time, there is no need to stretch this to include the form of the disease. With a normal nervous system, we see how events coupled with intense emotions in early youth become determinate for our whole lives. As Binet correctly remarks, when a child has once been frightened by a cat with no help at hand, or when it has been given a headache by the intense odor of a rose, the aversion for cats or roses may have been impressed upon the brain for life.

A pathological nervous system is usually more easily and intensely impressed; the neuropath is much less able to offer resistance to the sensations that have been intensely impressed upon him in youth. The idea created by the first strong impression of a sexual nature gains a growing mastery over him, and, for want of inhibitory opposition, forces him in a pathological direction. "Such a pathological inclination, as Lombroso says of criminals, in some evil hour develops, especially during childhood, and disappears under the influence of proper training. When, however, it has a favorable foundation (predisposition due to

[1] Revue Philosophique, Paris, 1887, No. 8.

faults of development), and when it is not opposed, it remains. While, in the majority of men, the reminiscences of such impressions, for the most part, influence them in a subordinate way through association of ideas, in the individual under consideration they operate like certain kinds of virus; since they not only become fixed, but also permeate the whole organism until they absolutely control it and irresistibly compel acts which are usually of a criminal character. Thus are explained the strange perversions in the direction of obscenity and love which we see develop in hereditarily predisposed individuals in their youth."[1]

The repetition, perhaps voluntary, of the first experience, if this induced sexual orgasm, and the reproduction of the perception with the onanistic act to which the majority of such individuals give themselves, change the vice into a habit, give the impulses the strength of imperative feelings,[2] and leave but one direction for desire. On the other hand, in the same degree in which the psycho-sexual anomaly is engrafted in them, such persons feel themselves impotent in normal intercourse. Women cannot charm them as long as they find satisfaction in the perverse activity of their sexual appetite.

Psycho-sexual Diseases, Moral Insanity, and Weak-mindedness.—The common characteristic of sexual perverts, therefore, consists of this: in comparison with the normally-developed man they have *lost the power to compensate* the *pathological stimulus* by means of the experiences of physiological sexual life and the multitudinous perceptions of life; or they have *never possessed* it, as in hereditary weak-mindedness.

[1] Comp. Lombroso, Der Verbrecher, Hamburg, 1887, p. 119.

[2] During the publication of this work there appeared, in the Münchener med. Wochenschrift (1892, No. 11, p. 188), a notice of the works by Moll and Krafft-Ebing. The reviewer, Dr. Bleuler, happily comes to an opinion similar to my own; at least, as a result of the opinion given by Professor Meynert on the case of Count Sandor, Bleuler says: "If, as a result of any accidental circumstances, these associations, which usually condition the exclusive inclination toward the normal sexual act, are so directed that the pleasure, in a broader sense, accompanying the activity of the sexual instinct becomes associatively connected with the idea of an 'unnatural' act, or of association with a person of the same sex, neurasthenic individuals and those predisposed to imperative thoughts often cannot rid themselves of this association, and there arises an *enduring abnormality of the sexual instinct.*" The correctness of this idea of the reviewer is confirmed by examples given later.

From the stand-point of lack of resistive power to pathological excitation, and from the stand-point of lack of inhibitory influence of our intelligence against intense stimuli, the various forms of sexual hyperæsthesia appear, from a single point of view, as members of one family,—as symptoms of a pathological condition which has been designated moral insanity. Moral insanity itself is but a symptomatic name for certain pathological manifestations which arise from a defect of mental endowment, or which, in their course, lead to destruction of the mental powers. According to the views of Mendel, Meynert, and Binswanger, moral insanity signifies a variety of weak-mindedness which is characterized by an abnormal tendency to immoral acts; a sign of a low grade of idiocy which is known under the name of "imbecility." The lack of inhibitory ideas (judgment) presumes a defect in the development of intelligence, in the mental energy, and it goes hand-in-hand with active stimulation of the animal instinct. The ethical weakness exists without disturbance of the understanding, but is often associated with great emotional irritability, and makes such persons incapable of recognizing and understanding immoral and illegal acts as such. Therein, in our opinion, lies also the reason why urnings but seldom designate their sexual instinct (comp. Moll, p. 205) as abnormal.

The instinctive and usually premature stimulation of the sexual sphere leads to perverse acts and onanism. Therefore, the perverse activity is always to be regarded as merely one of the manifestations of a nervous or mental disease. Too, the impossibility in some cases of demonstrating other abnormal symptoms than those of the sexual sphere must not lead us astray. For, as in all other diseases, in the perverse manifestations of the sexual instinct there are numerous transitional forms and varieties, from the slightest deviation from the physiological condition to the pronounced psychosis. Thus the old question whether contrary sexual instinct is to be regarded as "neuropathic" or "psychopathic" becomes meaningless. For it may be met as a symptom in apparently normal individuals as well as in cases of psychopathic weakness dependent upon

congenital disposition, taint, and degeneration, and in pronounced psychoses (paralytic, senile, epileptic pederasty).

Transitional Cases and Lessened Responsibility.—As it is impossible to regard crime in all cases as the result of pathological conditions, in spite of the correctness of the view that many crimes owe their origin to abnormal mental conditions,—*i.e.*, abnormalities of "those complex activities of brain which are inherited and automatic, and which we call character" (Forel),—so the medical expert is not called upon to allow that the *isolated existence* of perverse expressions of the sexual instinct occasions "irresponsibility." On the other hand, the unequivocal proof of psychopathic weakness should justify the assumption forensically, if not of temporary complete suspension of the freedom of the will, at least of lessened responsibility.

In case of gradually-developing mental weakness, the diagnosis is more difficult. In such individuals it is necessary to compare the present state of lessened mental activity with the former normal state. "Defective power of judgment, insufficient acuteness of critique, inability to distinguish the essential from the unessential, want of independent effort to investigate the cause and nature of things, mental one-sidedness, loss of creative power and originality of thought, are expressions of mental deterioration and diminished intelligence of various degrees which it is difficult to grasp. The manner of receiving external impressions and their fixation in consciousness, memory, understanding, logical powers, mood,—all must be taken into consideration in forming such an opinion. With diminution of intelligence and blunting of the feelings there is a want of the most powerful means of opposing the desires, the morality of which is judged by the understanding and estimated by the feelings" (Tarnowsky).

There are sensual persons in whom, at certain periods of life, the sexual functions are the most important thing in life. As soon as sexual power begins to diminish, as a result of excesses, they resort to various means to increase them. In this way there may arise a combination of impotence and sexual debauchery. Imitation is here one of the most powerful means

of spreading vice. Here the abnormal kinds of sexual activity do not arise impulsively from personal need, from organic necessity. The debased man employs all means that can add to his lustful pleasure, but, notwithstanding the greatest recklessness, is still able to control himself on occasion. Indefinitely marked transitional cases, in which it is impossible to decide where vice ceases and disease begins, are likewise not infrequent. But false philanthropy, in doubtful cases of "pathological viciousness," can only lead to the spread of immorality.

Sexual Instinct in Imbeciles.—In numerous cases which we find in literature, namely, in those where effemination has reached full development, there is, doubtless, mental weakness. Sollier[1] finds absence and perversion of the sexual instinct in idiots, but in imbeciles principally excessive intensification and inversion of it. The imbeciles often present an infantile condition of the sexual organs (Count Sandor), defect of sexual power, cryptorchism, phimosis, hypospadiasis, varicocele, arrest of development and atrophy of the testicles, defective development of the penis, etc.

The onanism of idiots, as a rule, is not to be regarded as an expression of the sexual instinct, as we have shown (Magnan). On the other hand, imbeciles often manifest premature development of the instinct and sexual perversions. Onanism is most frequent in the form of automatic masturbation as well as for sexual satisfaction; also, mutual onanism and pederasty. Too, there may be observed in them an especial tendency of the mind to obscene talk and gestures, which would be repugnant to a normally-developed person.

The alterations of sexual activity may also occur periodically and in the form of attacks, while during long intervals all is normal,—as in periodical psychoses.

Original Disposition in Paræsthesia Sexualis and its Proofs.—If now, in accordance with the foregoing view of the causes and development of the anomalies of the sexual instinct, we once more consider the hereditary relations previously de-

[1] Der Idiot und Imbecile (Voss, Hamburg, 1891), p. 75, and Bourneville and Sollier, Des anomalies des organs génitaux chez les idiots et epileptiques (Progrès Méd., 1887).

scribed, we may express our opinion as follows: Since only in the worst forms of hereditary degeneration are pathological states, as such, transmitted, it cannot be denied that there is a possibility of a repetition of the same form of disease, the same symptom-complex, directly or atavistically, in descendants. In accordance with this, therefore, in contrary sexual instinct there might be such a thing as the preformation of the feminine type in the male body without the influence of education and example. Quite analogously, the son of a shoe-fetichist might be a shoe-fetichist, and thus algolagny arise from an original disposition.

These cases, however, even if they occur at all, are the *exception* in common practice. As a rule, the transmission must be regarded as that of an hereditary lack of resistive power, which may well affect the sexual sphere by preference. On the other hand, the full development of the anomaly in the individual depends upon various accidental factors. The influences of the individual's life are, in the majority of such patients, determinate for the development of the form of the psycho-sexual disease.

But if, as acknowledged, the *possibility* of the occurrence of contrary sexual instinct as an hereditary symptom-complex, without or in spite of opposing education, cannot be denied, still, literature does not yet afford an incontestable example of it. Moll (p. 159) gives, as evidence of the original disposition, the circumstance that "in most pederasts and urnings the perversion dates back to the earliest childhood." The same author looks upon acquired cases as those in whom there was first inclination toward women, later toward men. This assumption seems to derive further support from the fact that the impulse to play the feminine *rôle* occurs prior to the time of the first sexual promptings, and that in spite of education. If, in such cases, the sexual feeling is directed toward the same sex, and without the occurrence of hetero-sexual feelings, then the "hereditarily-conditioned process" seems to complete its natural development.

This anthropological transformation reaches its acme when

not only the character, but also the skeleton, face, and voice correspond with the abnormal sexual type (defective development of beard, development of mammæ, abundant development of adipose tissue), to which, as a rule, other anatomical and functional signs of degeneration are added.

Objections.—But there may be serious objections raised to these considerations. The significance of the sexual factor in the development of mind and character is, of course, too important and determinate to be overlooked. Nevertheless, it seems to us to be necessary, in the interest of precise definition, to decide the question which Westphal raised, and which has been much defended by urnings, whether an individual with inclinations toward feminine pursuits, but feeling normal sexually, is to be regarded as of contrary sexuality. In our opinion, only the sexual element is to be looked upon as the determining one, and, to a certain extent, it insures the diagnosis. Thus, for example, I am acquainted with a cavalry officer who is a happy father and devoid of *sexual* anomalies; but he shows a great liking for feminine pursuits; he embroidered all the coverings of his furniture himself. In spite of his feminine habits, I do not regard him as of contrary sexuality. Likewise, I know a male nurse who knits his own stockings, cooks, and shows preference for other kinds of female work. He is perfectly normal sexually (verbal examination), and the happy father of nine children. Therefore, so long as the deviation from the same sex does not involve the sexual feeling, we are not justified, even in cases of the most remarkable opposite peculiarities which nature presents in many individuals, in speaking of a pathological phenomenon. Even when the feminine inclinations go to the extent of self-adornment, to the habitual use of perfumes and other unmanly arts of the toilet, the same position holds good. Skill in cooking, knitting, and sewing, without teaching and imitation, is impossible, and therefore, for the most part, the result of education.

In support of the above-mentioned anatomical transformation (development of mammæ, absence of beard, masculine feet in women) we may cite the observations made on eunuchs (who

lose the secondary sexual characteristics after emasculation) and the cultivation of mujerados. Here it cannot be denied that there is a certain correspondence between the physical phenomena and the psycho-pathological symptoms. But, as von Krafft-Ebing expressly points out, with contrary sexual instinct physical hermaphroditism has never been observed; and, on the other hand, in hermaphrodites there have always been found the characteristics and psycho-sexual peculiarities of but one sex.[1] Too, in this respect, nature presents remarkable variations; so that, with consideration of these conflicting facts, conclusions are to be drawn only with the greatest care. Thus, I know several cases in which, in perfect (physically and sexually) masculine individuals, there was development of female mammæ. One of my patients presented this remarkable condition; he also had a high, thin voice, was slenderly formed and neuropathic, but devoid of psycho-sexual anomaly.

The following personal observation, made in October of last year, also speaks against the rule of anatomical correspondence. It was the case of a bearded woman. She was tall; pelvis feminine; hands and feet large. Abundant development of subcutaneous adipose tissue; breasts well developed; hair thick and long and dark; cheeks, chin, and lips covered with a thick blonde beard of soft hair about six or seven centimetres long; voice deep and rough (like a man's); genitals perfectly feminine; age 34 years; menses began at the age of 20 years. She had been happily married nine years, and was the mother of one child. She loved her husband, and, with the exception of a strong will, she presented no masculine characteristics. She was entirely indifferent to the female sex, and had intense lustful pleasure in hetero-sexual intercourse.

Arrests of development of organs well differentiated sexually, as occasionally observed in individuals of contrary sexuality, are to be regarded as degenerative signs, as, for example, when observed in imbeciles. They exist independently of the psycho-sexual anomaly.

The etiological rôle of the educational factors and imagina-

[1] Tardieu et Langier, Dict. de méd., art. "Hermaphrodisme."

tion may be more precisely defined from experience that is at hand. The influences exerted on the child may, with defect of understanding, have an effect exactly opposite to that intended; unconscious suggestion, in the education of children, plays at least as important a *rôle* as systematic instruction. The question is, whether a child devoid of hereditary taint can become contrary sexually by cultivation; the possibility of artificial transformation—the extraordinary extent of human influences—after the historical and ethnographical facts adduced, can no longer be doubted.

The importance of the educational factor becomes perfectly clear after a consideration of cases in which this point is brought out, and we shall later make some contributions bearing on this point. Unfortunately, in the majority of histories of cases, this important point is not sufficiently considered. As a rule, such persons, as already mentioned, consult the physician only after they are forced to by nervous or other symptoms. The physician sees before him a many-sided symptom-complex; and if, with difficulty, he is able in every case to determine the degree of the deviation from the normal, and to recognize the anomaly of feeling as one of the phenomena of a deeper process, still it will be often impossible to decide what is primary, what is hereditarily conditioned, and what has developed secondarily. Thus, according to our view, the manifestations of effemination occur, as a rule, secondarily, as a product of accommodation. Besides, the physician, in examining the patient, has to depend largely upon his statements, and, owing to the required discretion, cannot control them by statements of the relatives. Too, almost every urning has formed his own theory; as the autobiographies in the "Psychopathia Sexualis" of Professor von Krafft-Ebing show, the persons of contrary sexuality who have not read that work are the exceptions. Unconscious auto-suggestion and retro-active illusions of memory concerning the events of early years give the histories a very uncertain basis. To this is added the pathologically intensified auto-suggestibility of such neurasthenics, which hinders in every way objective judgment.

The essential influences which determined the patient's sexual development are forgotten ; the theory of heredity shields him from responsibility ; concerning the time of the first occurrence of sexual inclinations he is often unable to make any definite statements, because the knowledge of the sexual relations followed only years after, and thus he seeks to explain the first signs of effemination by his original disposition, while, in fact, they are only resultant phenomena. If these autobiographical data are indispensable to the physician, still their value should not be placed so high that they are made the foundation of a wide-reaching scientific theory. The explanatory principles should not be increased unnecessarily; and to heredity, that unknown factor for us, phenomena should not be ascribed which may be easily explained by education and the effect of life.

The first intense sexual excitement may very easily occur in contact with an attractive male, without the necessity for the presence of hereditary predisposition, even though the latter can be demonstrated in the majority of cases. The previously undifferentiated feeling now has an object, and may, as a result of external influences, easily become developed into contrary sexual feeling before hetero-sexual feelings manifest themselves ; and if in such a case the latter occur, which in healthy, untainted individuals must be the rule, the inclination toward women is later than that toward men,—a contradiction of Moll's view previously mentioned, according to whom this factor is of decisive diagnostic significance for the original disposition. An imperative idea may be the starting-point of final complete effemination. If, among the perverse manifestations of the sexual appetite, contrary sexual instinct cover the broadest field, and seem, for the most part, to be a peculiar freak of nature, or to form a special pathological group, so that it has led to the expression "a feminine soul in a masculine body," still this depends principally upon modern education and the injurious separation of the sexes in schools.

Those persons in whose presence, or in whose companionship, the first sexual excitement is experienced, are, in these

cases, of like sex; too, the fetichist, before he has erections at the sight of lifeless objects, primarily, at least as a rule, becomes attached to some living person. The accidental causes, even in spite of the lively emotional accompaniment, are often forgotten by the patients; still in some cases, in which detailed biographies of urnings had been furnished, and from which no other explanation could be drawn than that of a congenital abnormality, I succeeded, after repeated careful examination, in awakening memory of apparently inconsequential events which were the keys to the physiological understanding of the disease. The fact that the remarkable perversions of taste of fetichists cannot be explained without the assumption of pathological association should point to the importance and the presence of a similar phenomenon in sexual inversion. The symptomatic picture which the patient presents to the physician on examination, usually in all the forms of paræsthesia, represents the ultimate product of an abnormal development that has existed several years or even decades,—the result of a great number of experiences and influences. Compared with its beginning, the result is totally different; and there may be nothing in the latter to recall the first associations, so important for the psychological analysis.

Thus, too, the most horrible of the sexual perversions, necrophilia, confirms the above-mentioned disastrous effect of the ideas accompanying the onanistic act, which, with a lively fancy, calls up changing images, any one of which, in a brain easily influenced by suggestion, may finally become an imperative idea. The auto-suggestive idea may induce an instinctive impulse to act,—a state of temporary impulsive insanity. The performance of the ideal act, auto-suggested or produced by external impressions, depends upon whether moral conscience is strong enough to balance the great suggestibility.

Thus, Tardieu[1] reports the case of an onanist whose heterosexual instinct was well developed, but who masturbated seven or eight times daily. He said: "While masturbating, my

[1] Attentats aux Mœurs, Paris, 1878, p. 114; also reported at length in Psychopathia Sexualis, p. 69, Case 23.

imagination places me in a room filled with women in my power. While I satisfied my lust on them, in thought, I sacrificed them always in the same way to my lust; imagined them dead, and then violated their bodies. Sometimes the thought came to me to cut up a male body; but that was always seldom, and disgusted me." The patient then began to carry out his fancies practically. At first he masturbated at the sight of the bodies of animals that had been cut open; then he killed dogs, and finally exhumed human corpses. "All that one experiences with a living woman," said he, "is nothing in comparison with the pleasure I enjoyed. I covered their bodies with kisses, pressed them wildly to my heart; in a word, I overwhelmed them with the most passionate caresses. Then I would cut up the body, tear out the entrails," etc.

Fetichism offers instructive examples for the theory of pathological association. In the well-known case of the lover of night-caps, the occurrence of the first sexual excitement coincided with the sight of a night-cap which was put on by an aged relative who slept in the same bed. The next erection occurred when the patient saw an old female servant put on her night-cap. Thus a mental association was formed at an age when mental impressions are always very deep. An apron-fetichist, at the age of 15, saw an apron fluttering in the wind; he took it and put it around himself, in order to masturbate while in it. Mental associations thus formed become imperative ideas, because the patients are hereditarily predisposed, and in this way determine the direction of the sexual life.

The psychical condition in which associations of such significance occur Binet has appropriately compared to a state of intensified suggestibility. In themselves, the objects with which sexual excitement becomes associated are often incapable of affording satisfaction; it is the reproduction of the associated ideas and feelings which give them their significance. Thus, the desire for generalization and abstraction, which is constantly recurring in these perversions, becomes explicable; and this, in the course of time, may entirely change the content of the perversion. A man who loved a red-haired woman finally

could not see red hair without becoming sexually excited. The former lover of an Italian girl always had an erection at the sight of an Italian costume. An original lover of white aprons was finally excited by every white apron he saw, and at last by white alone (on a mason). From the time of his first love Descartes had a partiality for squinting eyes. In general, the peculiarities which we have once loved in one person always have the greatest attraction for us in others.

The tendency to separate the object of love from its surroundings, as it is manifested in pathological fetichism, may be regarded as abstraction. The shoe-fetichist shows next a preference for the nude female foot,—an inclination which, without striving for isolation and without separate sexual excitement, is still physiological. The dressed female foot forms the transition, and the love of shoe-nails the pathological ultimate result. Tarnowsky[1] reports that the inclination for furs, in a masturbator 12 years of age, arose from the bodily contact with a dog that he sometimes took to bed with him. Transition: coincidence of onanism and the touch of the dog. Finally, the touch of the dog alone induced excitement and ejaculation. Later, only by means of touching fur could he induce sexual excitement. Here, also, we have to do with the effect of pathological association and the tendency to generalization in a degenerate individual.

The effort to intensify the cause of the pleasure and the sexual excitement indicates a longing for more powerful stimuli, and this, according to Binet, presumes a weakening of the power of reaction of the nerves, and therefore, in the history and in physiology, it is to be regarded as a sign of decadence. Even savages make prominent those portions of the body which they especially prefer; the natives of western America form the hair in knots in order to enlarge the head; the Chinese seek to make the feet small; Europeans try to make the breasts more prominent by means of tight lacing. The courtesan colors her eyelids to enlarge the eyes and accentuate the brilliancy of the sclerotic. Also, among individuals of contrary sexuality there

[1] *Op. cit.*, p. 22.

is the effort to magnify. Thus, the urning who tries to copy woman exaggerates the specific feminine peculiarities, often to caricature; and, *vice versâ*, the female in male attire (Count Sandor) those of man.

The restraint which is often enough connected with the fact of specific sexual reaction to stimuli that are not always attainable intensifies the sexual pervert's power of imagination and longing for satisfaction. From this may be recognized the correctness of the experience that regulated sexual intercourse is the most effectual antidote against the development of the anomaly.

The foregoing considerations show that the changes which the content of the sexual perversions may undergo in the course of time are essentially to be referred to the tendency of such patients *to generalize*, *to isolate*, and *to exaggerate*. These three peculiarities, however, are at bottom only different forms of expression of a single tendency peculiar to the human imagination,—namely, that of *exaggeration*. It may be intensified by pathological relations and abstinence.

The Exciting Cause in the Histories of Urnings and Other Sexual Perverts.—It remains to give a critical review of the known cases of sexual paræsthesia, and in them to try the correctness of the view here set forth, and especially to point out such cases as are exceptions.

In his "Clinical Novels," Caspar reports the autobiography of an inveterate pederast, from which we borrow the following passage, so important in showing the etiology of this case:—

"As a school-boy of eight I sat near a boy somewhat older. How happy I was when he touched me! It was the undefined feeling of an inclination which was a secret to me until my nineteenth year. I have never masturbated nor committed abuse with other boys. There were some certain ones toward whom I felt an unconquerable inclination, and to whom I indited my verses."

In sexual intercourse with women (at eighteen) he thought of his friend, and therefore had no pleasure; but "a wonderful feeling of joy" came over him when an unknown man in the Zoölogical Garden first satisfied him by means of masturbation.

Here we observe premature awakening of sexual impulses, transference of the undifferentiated feeling to the pupil touching him, passive onanism, and definite perversion of the instinct in a predisposed individual.

From Westphal's first case we take the following passage:

"N., it is said, suffers, since her eighth year, with a passion to love women, and, besides kissing and joking with them, to masturbate. She states that she has never had intercourse and never any inclination to it. Playing with them gave her such a sensual delight that she had actual orgasm. When a child she liked to play boys' games and dressed like a boy. She had experienced sexual excitement since puberty in kissing girls." [1]

She masturbated shortly before and after menstruation. In other respects the patient presented the female type.

Though in this case more exact details could be desired, still it may be seen from the report that there were (*a*) premature awakening of the sexual instinct, (*b*) relation to the same sex, and (*c*) masturbation. On the other hand, it is not clear whether the inclination to boys' play was present before or after the sexual inclinations for the female sex. Too, this case does not contradict our theory, and, like Caspar's case, does not require a forced explanation.

At this place it may also be pointed out that the theory of the development of the female character in the male body really owes its origin to the dualistic ideas of urnings (Ulrichs). Westphal[2] cites a number of passages from "Numa Numantius's" investigations of the enigma of male sexual love of males,[3] and,

therefore, was, perhaps, under the influence of the unconscious suggestion of this theory. He emphasizes that the feminine type is, embryologically, preformed in the infant, and favors the monistic and untenable conception of the imprisonment of a feminine soul in a male body. These writings lay stress upon the feminine inclinations of boys, and seek in every way to defend uranism. The time of the primary sexual excitation and accidental factors, education, etc., receive so little consideration that these studies, though highly interesting from the stand-point of present investigation, carry with them no weight of demonstration.

All the latest literature of uranism shows traces of the influence of Ulrich's theory. Important and fundamental as Westphal's observations are for psychopathia sexualis, they do not, as he himself states, afford an incontestable proof that contrary sexual instinct is congenital; still, both cases show great hereditary taint, which, however, only under the directing influence of exciting causes, became developed into contrary sexual instinct. Both patients, from youth up, presented a slight degree of psychical weakness; and, as one of the symptoms of it, the sexual perversion was developed as a result of external excitation.

Too, in Westphal's second case there was premature awakening of the sexual instinct (in the eighth year). The patient who states that in his youth he had a preference for feminine pursuits, says himself: "I have had some inclination for sexual intercourse with women, though seldom; for I feared to become ugly."

According to this, then, there was desire for women,

Love-bond of urnings. The conflict of urnings and its solution. The exceptional place of love in the moral status of the world. Hope. Leipzig, 1865. Leipzig, 1869.

as his later relations with females show. As he says himself, the patient did not give himself to men, in spite of many solicitations. On the other hand, he masturbated in youth; but we have no statements concerning the ideas that accompanied the act. This case is one of entire moral defect; it was not a desire for men (whose solicitations previously, and later while in the hospital, he actively repelled), but merely his desire for money which induced him to dress like a woman. And it was only after this, for the sake of material gain, that he assumed the feminine *rôle*, still, however, having intercourse with prostitutes, "who in a drunken state accompanied him home." Besides this, he stated that he once slept with a cook without touching her (?). Finally he became guilty of a series of thefts.

Here, as Westphal justly remarks, apparently we have to do with a weak-minded individual. When arrested he was suffering with gonorrhœa. In his case the sexual element certainly cannot be regarded as *congenital* contrary sexual instinct. His preference for female attire and his playing the feminine *rôle* are sufficiently explained by the circumstance that he was thus afforded a convenient source of revenue. Finally, we are not constrained to believe every statement made by a swindler; and we may remember, also, that deceptions of the imagination (pseudologia phantastica) occur in the weak-minded. The sexual feeling of the patient was originally normal; in our opinion it is a case of congenital weak-mindedness which, with other symptoms, but later, presented that of contrary sexual inclinations as a result of definite influences.

Dr. Schminke[1] reports another case of contrary sexual instinct in the *Archiv für Psychiatrie*:—

This case likewise speaks more in favor of the gradual development of the contrary sexual phenomena, with original normal tendency, on the basis of neuropathic disposition, than of original predisposition to contrary sexual instinct. The patient had no sexual intercourse until his twenty-fourth year. He became nervously ill as a result of typhus, and in Paris he fell into religious company. "Here, on one occasion, he was sitting on a sofa with a friend, both being in night-shirts. Suddenly he

[1] Archiv für Psychiatrie, Bd. iii, Heft 1, 1871, p. 227.

was seized with such a feeling of desire that he embraced his friend passionately, and at this instant he had a pollution." The reporter says: "However, it was remarkable to me that the patient also immediately had erections and slight emissions (of semen?) at the sight of beautiful girls; also when reading obscene books."

Here also the long-restrained sexual impulse became directed to the nearest object; friendly feelings and momentary intense excitement explain the perversion of the otherwise normal instinct. Both cases that Gock[1] contributes show that the mental weakness upon which contrary sexual instinct may develop is congenital:—

The first case is that of a servant-girl aged 28. She comes of a mother suffering with dementia. In school she was frivolous and did many foolish things; she masturbated from the time menstruation began (by means of tactile or psychical excitation). At the same time there was awakened a preference for young girls who attracted her by the expression of their eyes. This desire occurred, as a rule, before or after the menses. When she could kiss and embrace such a girl, she experienced lustful sensations in the genitals. If not satisfied in this way, she would think of the girl and masturbate.

She stated that, as a child, she preferred boys' games; whether this was the case after puberty is not stated. Later, she slept with girls and touched their genitals, which gave her the greatest lustful pleasure. With repression of her sexual excitement, she several times passed into a state of intense exaltation, undressed herself, and cried out; she grew quiet, when in bed with another girl, only after gratifying herself by means of onanism. States of excitement alternated with intense depression at the time of the menses. No feeling for men.

The first orgasm induced by onanism became associated with the sense-impression made by persons of the same sex that happened to be present. The irritable weakness of the psycho-sexual and genito-spinal centres, explainable by congenital neuropathic disposition, made possible the occurrence of lustful feeling as a result of the reproduction of the idea of girls' eyes. The memory-picture became habitual, and secondarily acted automatically. It then played the *rôle* of an imperative idea, and, owing to the lack of inhibitory opposing ideas, the patient became the victim of a cerebral process that had become inde-

[1] "Ein Beitrag zur Kenntniss der conträren Sexualempfindung, aus der Würzburger Psychiatr. Klinik," Archiv für Psychiatrie, 1875, Bd. v, Heft 2, p. 564.

pendent. The fancy elaborated the imperative idea, and the latter finally dominated the entire sexual existence,—*i.e.*, it became determinate for the individual sexual excitability.

Gock's second case illustrates the delusion of sexual transformation, and, with the other psychopathic symptoms, belongs entirely to the psychoses.

We find a further confirmation of our view in the case reported by Servaes,[1] which recalls the origin of contrary sexual instinct among the ancients:—

Franz E. was misused for pederasty in his ninth year by the tutor of his friend, and from that time was not able to give it up. Arrest on account of suspicion of immoral relations with a night-watchman. To him carnal intercourse with men is the highest pleasure in the world. Unmitigated cynicism. Stole from his room-mates. Unconquerable aversion for women. Onanism. Exaltation alternated with depression until death. Female inclinations. He made ornamental covers out of linen. Increasing weakness; ideas of persecution. Death due to tuberculosis.

This case, likewise, does not strengthen the theory of heredity. The fact that the patient allowed himself to be used for pederasty may be regarded as a sign of lack of resistive power dependent upon inherited weak-mindedness. If, however, we assume that the case is one of acquired contrary sexual instinct, with congenital imbecility, in favor of which the theft and other peculiarities speak, then it clearly demonstrates that the feminine character may be the result of the assumption of the female *rôle*, in the same way that devotional or theatrical employment cultivates a certain type.

In the second case reported by Servaes, there were maniacal outbreaks alternating with states of melancholic depression. Sexual inclinations were manifested during the outbreaks of excitement; she threw herself on the female nurses and overwhelmed them with caresses. The first evidence of menstruation came after the second attack. Maniacal excitement, with contrary sexual instinct at the time of puberty. Recovery.

The brain, powerfully stimulated by indifferent sensual excitants, convulsively seeks for some compensation, and accepts

[1] "Zur Kenntniss von der conträren Sexualempfindung," Archiv für Psychiatrie, 1876, Bd. vi, Heft 2, p. 484.

the first person at hand. This person is a female,—the more a reason why a girl, perhaps unacquainted with the sexual relations, should trustfully make an approach. Convulsive effort of nature to complete sexual maturity. The intensity of the sensation attending the first orgasm may continue determinate in weak and hereditarily-disposed brains; but in persons otherwise normal it becomes compensated by further normal development, which was the case in this instance.

The following case, reported by Fränkel,[1] speaks still more forcibly for the transformation of the male into the female type, possibly by means of cultivation, and facilitated by congenital defect of resistive power:—

> The patient at first had assisted his mother in sewing and embroidering, and then became so proficient in all kinds of feminine work that he obtained a great reputation and some return for his embroidery and hanging of curtains. As a result of his occupation in feminine work, he gave himself to feminine vanity, carefully destroyed his beard, dressed his hair in curls, padded his bosom and hips, and used every opportunity to mask as a woman. What at first was merely silly affectation gradually assumed another nature: the tone of his voice, naturally low, became high and shrill; the gait, tripping. Blank made application for permission to dress as a woman, and, though dismissed, he one day showed his betrothal to a foreign mechanic under the name of "Friederike Blank." The patient, whose genitals were normally formed, approached men and, dressed like a woman, performed coitus with young men whom he was able to deceive so skillfully that they thought they were engaged with a woman. The anus was much dilated and torn. When arrested he killed himself by jumping into the water.

According to these statements it would seem that Blank became feminine as a result of his engagement in feminine pursuits to which his mother introduced him. At least, as Westphal remarks, it is a case of imbecility and moral insanity, which is also confirmed by other perverse inclinations (theft). Why, in this instance, with the demonstration of the influence of training, contrary sexual instinct must be assumed to have arisen from original disposition is not clear.

Interesting and confirmatory of our view is the report of

[1] Medic. Ztg., herausgegeben vom Verein für Heilkunde in Preussen, Bd. xxii, 1853, p. 102; Homo mollis.

the Director of the Penal Institution of Brandenburg, Westphalia, which is to the effect that the practice of feminine occupations by men in the institution may occasion feminine conduct.[1]

As we have seen in the cases reported, congenital imbecility constitutes an important basis upon which, with appropriate external influence, contrary sexual instinct, with the secondary phenomena of effemination, may develop. In this development we see the predominance of imperative feelings, conceptions, and acts. Further, states of depression and exaltation, alternating periodically, are observed. The unusual intensity and the premature manifestation of the sexual instinct, resulting from hereditary disposition, fill the fancy and drive such individuals to act on the impulse, in which the stimulus of the unusual may also play a *rôle*. Always, however, after close study of the history, we find how external circumstances exercise a determinate influence upon the form of the perversion. If, however, in such cases external influences seem to play a greater or as great a part as hereditary predisposition, still it must be allowed, on the other hand, that in other cases the original disposition is the determining factor. This is true, for example, of many cases of lust-murder (anthropophagy), violation of corpses, etc., reported by von Krafft-Ebing. To a certain extent algolagnists constitute a transition; in some cases pathological association seems to play the principal part; in others it is not possible to demonstrate determinate educational causes, and the congenital disposition seems to exercise the principal influence. Thus, Case 29 of "Psychopathia Sexualis" favors association:—

> An hereditarily-predisposed neurasthenic was present by accident when his mother's servant cut her finger on a broken pane, while washing windows. When helping to stop the bleeding, he could not keep from sucking up the blood from the wound; in the act he became violently excited sexually, experiencing complete orgasm and ejaculation.

In this case it is quite possible that the servant-girl had previously excited the boy sexually, who was given to onanism;

[1] Comp. Westphal, *loc. cit.*

and he may have been unconscious of it. The accident brought them into bodily contact. Violent erection and psychical onanism. The idea of sucking blood may have been derived from reading; for such an act is described as customary after snake-bites and other kinds of poisoning. The patient became an active algolagnist.

In the case reported by Moll (Case 30, in "Psychopathia Sexualis"), the patient, when a boy, read of the abuse of Roman slaves, and the thoughts of whipping and subjection formed the content of ideas accompanying onanistic acts. In this way the patient became a sadist, which, upon the theory of pathological association, is easily explained.

Acts of a purely symbolic nature with an algolagnistic purpose, which merely indicate the relation of subjection, are, as von Krafft-Ebing shows, fully explainable by pathological intensification of accompanying phenomena of the vita sexualis. Very often we find that algolagnistic inclinations arise at the sight of boys being whipped at school, where accidental sexual excitement is associated with the perception of the flogging, then to become effectual in psychical onanism, and, finally, to become an imperative idea.

Von Krafft-Ebing regards foot- and shoe- fetichism as a transitional form of masochism (passive algolagny) to fetichism; elements of both anomalies are combined in it. And he allows Binet's theory of association to hold good for pure fetichism. The first awakening of the sexual instinct is connected with a partial sexual impression; it becomes independent, and finally becomes a *conditio sine qua non* of sexual power; and it is then pathological. "The occasion," says von Krafft-Ebing, "on which the association occurred is, as a rule, forgotten." Therefore, it is clear that many cases of the autobiographical kind are unable to answer the question concerning the origin of the anomaly.

The significance of the exciting causes is placed in the clearest light by careful observation of contrary sexual individuals.

In Case 95 of "Psychopathia Sexualis," we have to do with Ilma S., who is very sensual, but of normal feeling, made

familiar by von Krafft-Ebing's "Experimental Study in the Domain of Hypnotism."[1] To support herself she donned male attire, became a tutor, and finally gave up her place; but she at last became accustomed to her *rôle*. Instinct and inclination for the same sex, but without transformation of character.

In Case 72 (mutual onanism) and in Case 73[2] the desire for change, which came with increasing sexual decadence, became the starting-point of the instinct and inclination for the opposite sex.

In Case 72 the patient had been an excessive onanist since his eleventh year, as a result of seduction. Nothing is said concerning the ideas accompanying the act. In a brothel he was impotent, which, in my experience, may occur in youths without perverse disposition. Seduced to mutual onanism, he became contrary sexually and his character feminine. Von Krafft-Ebing correctly remarks that this is a case of acquired contrary sexual instinct.

In Case 75 the first sexual excitement of the patient (female) became connected in a platonic way with a lady, without any idea of the sexual relations. Marital intercourse compensated the instinctive impulse entirely, which appeared again only with abstinence (widowhood), and became expressed in auto-masturbation. In my opinion, the exciting cause in this woman, neuropathic by heredity, was alone determinate for her homo-sexual inclinations.

In Case 76, the patient, T., masturbated from his eighth year. What *rôle* his fancy played in this—whether it conjured up for him male persons as a result of accidental association, or not—he does not say, though that may have been the starting-point of his perversion. That the feminine inclinations occurred before the first indulgence in masturbation also seems questionable.

The origin of the perversion in Case 77 is very characteristic. A small boy saw his sister change her hose. When she

[1] Translated by Chaddock. G. P. Putnam's Sons, New York, 1889.

[2] These numbers refer to cases in the sixth German edition of Psychopathia Sexualis, and cannot be identified in the English edition.

quickly concealed her feet it excited the boy's attention (probably the first sexual excitement). Soon the sight of her feet to the ankles became the object of his desire. Since the sister objected, there was soon a struggle, which the patient carried on "with all the wiles of cunning and flattery, even to explosions of anger, until his seventeenth year" (beginning of sadistic inclinations). *Faute de mieux*, he availed himself of the feet of servants; had lustful dreams about cutting corns and toe-nails (beginning of fetichism). When the patient was about 13 years of age, a comrade, who was sleeping with him in the same bed, kicked at him with his naked foot. The patient seized the foot. Intense sexual excitement; first pollution. After that many male persons excited the patient sexually (psychological cause of contrary sexual instinct). The idea of a girl getting a thorn in her foot and its being removed by a boy gave him an erection when a mere child. This mixture of contrary sexual, sadistic, and fetichistic elements was compensated by normal sexual intercourse. Owing to his lack of resistive power in sexual relations, the patient became the slave of external influences, the quality of which determined the nature of the perversion: an excellent example of the origin of each of these perversions in pathological association.

In Case 78 the contrary sexual instinct was likewise acquired as a result of mutual onanism. Details will be found in the therapeutic section.

The subject of Case 79 was a shoe-fetichist from his fourth year (so stated), with contrary sexual instinct. Hetero-sexual intercourse is possible with the help of ideas of shoes. There is no doubt of the hereditary predisposition of the patient: his father is said to have had a preference for handsome lackeys. In this case, if the perversion actually appeared complete in his fourth year, there could be some thought of original disposition due to heredity.

In Case 80 the sexual instinct appears in the eighth year, and becomes connected with (the nearest object) the sight of his brother's genitals. Mutual handling until the patient had erection. Repetition; mutual onanism; coitus inter femora

when 13 years of age. Later, horror feminæ. After the greatest difficulty, coitus is finally performed; but it never satisfies him, though the patient marries and becomes the father of four children. In this case, likewise, the contrary sexual instinct is not necessarily due to original disposition. The sexual education of this man, wanting in resistive power because of hereditary taint, seems to us to afford the explanation: the instinctive anomaly rules too completely the patient's entire existence to allow compensation by normal sexual intercourse.

The subject of Case 81 noticed the awakening of his sexual instinct in his sixth or seventh year; at that time he induced a playmate of his own age to show him his genitals. Mutual handling, mutual onanism. During the next ten years uninterrupted sexual relations with friends; knowledge came in his eighteenth year. Horror feminæ. Complete homo-sexuality.

In the fact that children, as soon as they become aware of their sex, look at their genitals, I can see no indication of congenital sexual perversion, nor in the curious handling of the genitals of their playmates, that leads to sexual excitement and mutual onanism. In Case 81, also, external influences are sufficient to account for the pathological direction of the instinct; for systematic cultivation could not be more effectually practiced than it was in this case as a consequence of unfortunate relations.

In Case 82, likewise, the sexual associations, with intense feelings, seem to have arisen accidentally when the patient was in bed with a companion (handling of the erected penis).

The subject of Case 84 states that in his third year (if there is not an illusion of memory) he took an interest in the handsome male forms depicted in fashion journals. Inclinations to play with dolls. From the age of 13 to 15 the patient slept with a man and masturbated. Even though this circumstance may have given opportunity for pathological association, still the patient's statements seem, allowing that they are correct for the conditions existing before his tenth year, to speak in favor of original predisposition.

In Case 84, a schoolmate, aged 15, placed the patient's

hand (aged 13) to his open trousers with onanistic intent. The patient's sexual feeling, until that time indifferent, became intensely excited and perverted. From that time his friendships took on a sexual character. At the age of 19, mutual onanism and development into an urning.

In a similar manner, in Case 85, this subject learns onanism at the age of 6 by having his genitals handled by an elder playmate. Enthusiasm for handsome playmates, desire to touch their genitals, etc. When the patient came to play with girls, his impulse to onanism had already become so powerful that no compensation took place.

In the writer of the autobiography of Case 87 the awakening of the sexual impulse occurred in his third year, without, however, being directed to the male sex. He often sought, for example, to look under women's skirts, to touch a friend's genitals, and to stroke the anus of the coachman's son. At the age of 5, inclination toward a playmate (perhaps induced by manipulations of the genitals). At 14 the patient became a psychosexual hermaphrodite; he loved young girls, but no more than he did boys. Then came solitary and mutual onanism. After touching male genitals his ideas in sexual matters were about persons of the same sex. Complete development into an urning.

The writer of Case 88 asserts that he has been an urning from the beginning, and doubts whether onanism practiced from youth could induce inversion. According to his statement, his first sexual promptings occurred in his tenth year and were directed exclusively to men. Onanism began in his twelfth year. It is not stated what external circumstances influenced the indifferent impulse. If illusions of memory as to the time of the first sexual excitement are not in play here, this case may also be explained, in spite of its defects, in the same manner as the preceding.

The autobiographer of Case 89 experienced the first sexual excitement at the age of 9 or 10, when his tutor let him "ride horse" on his leg. The impulse then remained directed to men. Whether the inclination for feminine pursuits occurred before or simultaneously with the excitement (which is the more

probable) is not stated. The impulse became confirmed by onanism with thoughts about men. Coitus possible, but devoid of satisfaction; successful only with the help of thought of men.

In Case 90 an original disposition may be presumed. A cousin of the patient is contrary sexually, and he states that he took the part of a girl before the occurrence of his sexual perversion. Mutual onanism from his thirteenth year.

The subject of Case 91 (female), greatly predisposed, suffering with imperative ideas, remains neutral sexually until her twenty-eighth year, then falls in love with a lady five years younger. Mutual onanism. As in the majority of cases, in this instance the first sexual excitation exercises the most enduring influence upon the patient's life. Marriage and the duties of a mother later are incapable of erasing the primary impression. She is unhappy in married life.

The patient (female) in Case 92 shows signs of intense sexual excitement in her thirteenth year, which is expressed in enthusiastic love for a friend of her own age. By this means her sexual peculiarity seems to have been determined. Marriage does not cure her. She goes on to inversion and probably gratifies herself in mutual onanism. Nothing is said of masturbation from her thirteenth to her eighteenth year.

This completes the review of the cases reported by von Krafft-Ebing as congenital contrary sexual instinct (homo-sexual individuals, or urnings), Class I (inversion of the sexual instinct). From this *résumé* we see that the influences of education, with two or three exceptions, can be shown to have exercised a determining effect.

Neuropathy or psychopathy was hereditary. The few exceptions are perhaps to be explained by imperfect history or the self-deception of urnings, which, according to Binswanger's[1] view, in "conscious" or "unconscious" form is nowhere more probable than in the sexual sphere.

Not one of the cases cited has impressed us as if the woman had been developed *ab ovo* in the male body.

We come now to the class of "Effemination and Vira-

[1] "The Employment of Hypnosis in Asylums," Therap. Monatshefte, Heft 3, 4, p. 167.

ginity." Case 93 seems to speak in favor of the isolated influence of educational factors, for the patient's father states that the patient became interested in female toilettes, and helped his sisters do dress-cutting, etc. Unfortunately, we learn nothing on the most essential point. From the description it is possible that the patient's effemination was developed as a result of causes forgotten,—causes which directed his sexual feeling to male persons. In that case, his feminine employment may have been but a secondary accommodation to his assumed *rôle*, and thus explainable like previous cases.

The writer of Case 94 did not experience ejaculation until his twenty-eighth year, but from his thirteenth had directed his sexual feeling to boys; and his character had developed into that of a woman, sexually, without the occurrence of compensation of this platonic tendency by association with women. Concerning the first association the patient gives no satisfactory statements. It remains doubtful, therefore, whether accidental cause or original disposition was of greater influence in the production of effemination. In conclusion, the patient himself asks the question whether this result was not brought about by too great laxity of training.

The patient in Case 95 makes such incomplete statements concerning the awakening and association of his first sexual excitement that we cannot use this report—which represents the final result of a long process of development, under the influence of which it is written—for our purpose. We learn only that inclinations for men appeared in his thirteenth year; nothing is said of onanism.

The abnormal instinctive tendency of the writer of Case 96, according to the description, seems especially to have arisen from original disposition. An uncle contrary sexually; no emission until the twenty-sixth year; no onanism. Still, there were violent erections from the age of 13, which would not cease, and which ended with nightly pollutions in erotic dreams of male persons. Whether, in this instance, the original sexual neutrality was given a perverse direction toward men by external circumstances, and thus the imagination became occupied

in the same way, remains doubtful. In such case the effemination was here also to be attributed solely as a result. As far back as the patient could remember, his development of character had been feminine.

Count Z., subject of Case 97, began masturbation at the age of 11, and during that year, in church, a man made a fascinating impression on him. At the age of 13, neurasthenia spinalis and inclinations toward men. Preference for dolls and girls' games. Horror feminæ. Great hereditary taint.

Two sisters of the patient who is the subject of Case 98 love men. At the age of 13 the patient was seized with a passionate love for an elderly officer. He remained true to his perversion after this incident. Onanism and impotence with women. In this instance, also, the possibility of cultivation does not seem to me to be excluded.

If it be possible to defend original disposition in the two cases last mentioned, it does not seem possible in Case 99. The patient felt his sexual instinct awaken in his eighth year, and had the idea penem aliorum puerorum in os arrigere, to which he may have been brought by circumstances that are not mentioned. Great pleasure, and determination of his feeling toward men. Later, he was able to perform coitus, and he became the father of two children. The effemination seems to have been developed secondarily. Educational influences operating upon one hereditarily predisposed may here be taken as offering an explanation.

The subject of Case 100 found, as early as at the age of 5, his greatest pleasure in seeing a penis, and for this purpose he lounged about appropriate places. Onanism before puberty. In this case, apparently, circumstances not mentioned must have turned the boy's attention to the penis (exactly as in the case of one of my patients). Later, love of friends; sexual intercourse with men; effemination, in spite of complete development of the male sexual character (beard and voice).

Cases 101 and 102 contain only notes without etiological points. The last case of this class, Case 103, is that of a servant-girl afflicted with original paranoia and hysteria, who

never had felt inclination for men, but for female friends. Enthusiastic love for persons of her own sex from the time of puberty. The report contains no more detailed description of the origin of the sexual perversion; so that the question whether the original disposition or educational influence was more largely responsible for the origin of gynandry must remain open.

As we have seen from the foregoing review, there has been no absolute proof in any case of the origin of contrary sexual inclinations and effemination with exclusion of the influence of training. Even the doubtful cases could possibly be explained, on closer examination of the pathological association of the first sexual excitement and the person immediately at hand. In every instance we find inability to overcome, by opposing ideas and normal sexual intercourse, the confirmed perversion (as a rule, by onanism with corresponding dream-pollutions) that has arisen as a result of some accidental impression,—a weakness that is to be ascribed to the hereditary predisposition, as is the premature awakening of the sexual instinct which is in these patients.

In his "Psychopathia Sexualis," von Krafft-Ebing gives three cases of gynandry and androgyny.

The subject of Case 104 is a person defective *ab origine*, affected with neurasthenia spinalis, which is ascribed to the causal influence of masturbation. At the age of 22 the patient associates with women, performs coitus normally, but, owing to imperfect satisfaction, he turns away from the female sex. Thorax and pelvis of feminine form; slight growth of hair on the mons veneris, which is prominent and plump. Voice high, without masculine timbre. Patient is neuropathic in such a way that the sexual perversion represents but a partial symptom of his condition. It seems to arise from abnormal organic conditions.

The patient (female) in Case 105, aside from masculine manner, presents coarse features and a rough, deep voice. Bosom and pelvis feminine. She grew up with a preference for masculine pursuits, but there are no other details given of educational influences. Corresponding with her *rôle*, she feels like a man, and later becomes associated with women.

It seems to me questionable whether the few physical signs (voice and coarse features) alone justify the assumption of gynandry in the presence of a type otherwise feminine. It would be interesting to know how the patient came to assume the masculine *rôle*. The history of the case does not deny the possibility that the inversion of sexual feeling was brought about by educational influences.

The subject of the last detailed description (Case 106) is the notorious Count Sandor S.; in reality, Countess Sarolta V. The details of this history are too well known to require repetition here. The physical signs indicative of gynandry in the patient, according to Birnbacher, are: (*a*) general narrowing of the diameters of the pelvis, which is of the male type; (*b*) straight thighs, infantile female genitals, trunk devoid of waist, voice deep and rough, breast fairly developed.

The opinion of Dr. Birnbacher and Dr. Josch was to the effect that Countess V. was suffering with congenital neurasthenia, congenital mental disease in the nature of elementary disturbance of mental function, and contrary sexual instinct depending upon the same basis; and that therefore she was to be regarded as insane.

In a supplementary statement the same authors state that the acts related to the sexual instinct arose from a kind of organic necessity which recalls the so-called imperative acts of certain insane patients.

The opinion given in the higher court by the faculty of Vienna, signed by Theodor Meynert[1] as referee, declares that the patient is irresponsible, but contains another view of the disease. The facial bones, the position of the teeth, and the pelvis are called rachitic. "Owing to the father's influence she was early educated as a boy, and, as a result of this, deprived of the educational influences of an ethical orientation of the simplest things connected with her station in life and her duties to her fellow-beings. . . . Carried away with poetical fancies, she gave herself the form of a man dressed in her boys' garments, like Don Juan. Besides male garments, her conduct was allowed

[1] Comp. Friedreich's Blätter für gericht. Medicin., Nürnberg, 1891, Heft 1, p. 36.

to be unrestrained,—the very opposite of a girl's education." Sexual feeling at the age of 12, which, corresponding with her early preparation, found its first satisfaction in contact with a young English school-girl. Thereafter, comradeship with males. Relations with women, while men were indifferent. Drinking, smoking, night-carousals, etc. "By using a glove a penis was imitated. She retired behind trees to give the impression of urinating like a man; said her menstruation was due to hæmorrhoids, etc. She once stated that she had to engage in military drill, and said she had a scar on her arm from a wound received in a duel." The referee opposes the theory of congenital masculinity with female genitals, and emphasizes that the countess is practiced in the imitation of masculinity; that doubtless she directs the tone of her voice accordingly; that she imitates masculine immorality, and "overdoes the matter."

The fact of growing up in male attire is not given sufficient weight by the experts. According to this view, Countess Sarolta V. suffers with imbecility with excitement, and, owing to her weak-mindedness, she is unable to judge her own acts, etc.

"In combination with other excesses—tricks, absolute social looseness, prevarication, drunkenness—the symptom of contrary sexual instinct constitutes the patient's degeneracy, for which the name 'moral insanity' is largely in use. The latter is but a symptom of congenital imbecility."

The occurrence of Westphal's contrary sexual instinct Meynert holds always to be accidental. The sex with which early sexual impressions happen to become connected, in abnormal individuals, determines the occurrence of this symptom. Imitation and education develop all the ultimate characteristics of the sexes. At any rate, and we agree with Meynert in this, this case is very instructive as showing the exciting cause of contrary sexual instinct.

The remaining cases of contrary sexual instinct reported in "Psychopathia Sexualis" are concerned with therapeutics, and are considered in the therapeutic part of this section.

The foregoing critical review with respect to the influence

of education is sufficient to confirm our theoretical propositions concerning sexual development; and, therefore, for the sake of brevity as well, it does not seem necessary to extend this examination to cases in von Krafft-Ebing's "New Investigations in Psychopathia Sexualis."

While, as we have seen, in the cases given in "Psychopathia Sexualis," the principal emphasis is laid upon the original disposition dependent upon hereditary influences, some of the reports of perverse sexual instinct made by Hammond are instructive for us, owing to the consideration of the exciting causes. At least, Hammond[1] points out that in cases in which individuals entertain the delusion that they belong to the opposite sex (*vide* von Krafft-Ebing's "delusions of sexual transformation"[2]) are not to be confounded with cases of this kind, "for they are cases of actual monomania, and are seldom combined with other pathological sexual symptoms."

The importance which educational factors and external influences may attain in the origin of sexual perversions, as a result of pathological associations in the case of hereditary neuropaths, is illustrated by the following cases, reported by Hammond:—

A boy, aged 7 years, who was hereditarily predisposed, was taught to masturbate by a servant-girl. At first she induced erection by touching his penis with her foot with the shoe on, and thus the patient experienced his first sexual pleasure. From that time sexual excitement and erections at the sight of women's shoes; later, at the mere thought of them. Onanism in the midst of women's shoes, which he placed about himself in all sorts of positions. Then psychical onanism by means of the thought of women's shoes. At school, sexual excitement due to the teacher's shoes. Partial concealment of the shoes by long skirts induced especial pleasure. In order to intensify his sensual excitement he one day seized his teacher's shoe, and experienced greater pleasure than ever. Sexual orgasm. In spite of punishment, repetition of the act, with like result. Later, the mere memory of his teacher's shoe induced ejaculation. After that he purloined the servant-girl's shoe and ejaculated in it. New variations by using a different shoe with each act of onanism. He stole shoes for this purpose. Nude women or men excited only feelings of disgust. He never thought of sexual intercourse. Finally, he

[1] *Loc. cit.*

[2] Krafft-Ebing's "New Investigations" gives very pregnant examples.

sold shoes in a store. Sexual excitement while fitting them. On one occasion, while fitting a pair of shoes, powerful erection without orgasm; loss of consciousness and an epileptic attack. Determination to marry. Impotence in marriage. On Hammond's advice he hung a shoe over his head; simultaneous treatment with bromides. Coitus was then successful, and without epileptic attack. Later, regular sexual intercourse once in ten days. The thoughts of women's shoes came to him still now and then, but without exciting him sexually.

This very remarkable case, as Hammond remarks, shows that a strong will, even in a man of no great intelligence, is capable of redirecting an abnormal instinct into its normal path.

Another of Hammond's patients, a cigar-dealer, in childhood saw a dog and bitch copulate. Believing that this took place by means of the anus, he passed a lead-pencil into his own rectum. "This caused him local pain, but also a peculiar feeling of pleasure, the localization of which he could not at first make out." After a few days he repeated the experiment with similar result, but this time used the handle of a tooth-brush which he had previously oiled well. Again he experienced a pleasurable feeling, and that in the penis. From this passive pederasty was developed.

Moll,[1] who "will not deny that accidental causes are not without value," assumes that there was doubtless an abnormal disposition in the boy. "How could he," asks Moll, "otherwise have had such a pleasurable feeling on inserting the lead-pencil in his anus as to be led to repeat it so frequently?" Even if the patient were the subject of an inherited neuropathic disposition, which Hammond's report does not make clear, it would not be necessary to regard it as an original inclination to pederasty. Local irritation of the rectum alone is sufficient to induce erection, and therefore causes sexual excitement, as has been repeatedly demonstrated on impotent debauchees in removing foreign bodies from the rectum.

From pederasty contrary sexual instinct was developed in the patient; he put on feminine attire, called himself "Lida," and never had inclination for women after the undifferentiated sexual feeling had been given a definite direction. He later had epileptiform attacks. He stated that he had performed pederasty at least ten thousand times, actively and passively.

[1] *Loc. cit.*, p. 163.

The desire to be a woman became so intense (as in the pathici of the ancients and in some of von Krafft-Ebing's patients) that he repeatedly thought of amputating his genitals.

In the following case, by Hammond, accidental local irritation (of erogenous areas) seems to have been the starting-point of the perversion:—

A boy, aged 12, was severely punished in school for a mischievous prank; soon after he had an erection lasting half an hour, with a peculiar feeling in the glans which he had never before experienced. The same afternoon he went bathing with a companion, and while in the water he placed his hands on his companion's shoulders. He had often done this before without experiencing sexual excitement. On this occasion his penis touched his friend's gluteal region, and immediately he experienced the same feeling with erection that he had had after being punished. They were near the bank, and, without being conscious of it, he performed pederasty (immissio penis in anum?). From this time he continued the vice, partly passively, but for the most part actively by preference. Sexual excitement induced by nude men; onanism. Ideas: male gluteal region; dream-pollutions of a pederastic nature. Women had no power to excite him. He remained an active pederast.

Hammond's treatment freed him entirely of his perverse tendencies. It consisted of "study of mathematics, hydrotherapy; cauterization of the cervical, dorsal, and lumbar regions; bromides, and family social life." After a few months essentially improved; sexual inclinations for women; marriage.

The following case is also interesting, though in some respects it seems to speak in favor of the theory of original predisposition:—

The patient, father of four healthy children, the issue of an extremely happy marriage, according to his own statements, before puberty had a decided preference for household work and feminine games and dress, though he came only to wear girls' shoes. His preference for feminine attire grew later, as well as that for acting feminine *rôles* on the stage by men. At the age of 21 he wore corsets, laced himself, and stated that he thus experienced great sensual satisfaction. No onanism, but involuntary ejaculation three times while putting on and buttoning a pair of very tight shoes (ladies' shoes with French heels). After his marriage he no longer wore corsets.

In spite of a happy marriage, after several years the same ideas returned. He was accustomed to put on and button ladies' high-heeled shoes, which induced erection and ejaculation. Ideal cohabitation at the

sight of a lady tightly laced and with elegant feet. Again he wore corsets, and, to increase the pleasure by novelty, he bought other articles of feminine apparel,—a black-silk gown, curls, hoops, false hair, and earrings. He padded his breasts, laced, and put on an enormous bustle. He had his hair dressed fantastically in the ladies' fashion for hours at a time. He persuaded his wife to lace. He dressed himself up as a ballet-dancer, Queen Elizabeth, a Polish lady, an old maid, the Goddess of Liberty, Julia, etc.

In this very interesting case, unfortunately, we learn nothing of the manner of origin of the pathological association,—that is, nothing of the external circumstances which were operative in inducing the preference for feminine dress. In this case, as was remarked in opposition to Westphal's view, in our opinion, we are not concerned with a case of contrary sexual instinct, for the sexual feeling, as the happy marriage and the four children show, was perfectly normal, and underwent no essential alteration as a result of the imperative ideas. At most, the case might be called one of psycho-sexual hermaphroditism. In spite of the feminine *rôle* and the erotic fetichism, the sexual feeling remained normal, and the imperative idea only concerned dress. Had the patient masturbated excessively, and thus intensified his perverse tendencies, he might possibly have come to assume also the feminine sexual *rôle*. This case shows clearly that we are justified in speaking of contrary sexual instinct only when the sexual feeling is demonstrably implicated. Subsidiary symptoms, like preference for ornament and feminine work, or specific feminine peculiarities of character, are not by themselves sufficient to justify a diagnosis of sexual inversion, though they may easily become the starting-point of it, for proof of which, in the foregoing case, the erections and ejaculations may be noted.

How very influential external circumstances are in determining the sexual character is shown by the following case, reported by Rouboud[1]:—

A general's son, while a pupil at a military school, at the age of 14 was introduced to the pleasures of love by a young lady, a friend of the

[1] Rouboud: Traite de l'Impuissance et de la stérilité, 3 éd., Paris, 1876; and Hammond, *loc. cit.*

family. This lady, then 21, was a blonde, wearing her hair in the English fashion,—in twisted locks; and, to avoid detection, she had sexual intercourse with her young lover only while dressed in her usual garments,—skirts, corsets, and a silk gown. All these peculiarities finally had the greatest influence not only on the intensity of excitement, but also merely on its occurrence. This exceedingly sensual young lady exhausted the boy's strength, and only the strict discipline of the military school was capable of restoring the sexual organs, which had been overstimulated by too early and too frequent use. Finally, after leaving the school, the patient noticed that his sexual desire could be excited only under definite conditions,—by certain women. A brunette could not excite him; a female in night-costume might stifle all desire in him. In order to excite his desire, the woman had to be a blonde, and wear skirts, a corset, and a silk-dress; in short, be dressed like the woman who had first excited him sexually.

Similar pathological associations may so operate as to render a husband virile only with his wife, or to make a debauchee impotent on his marriage-night. This relative impotence is due to one-sided determination of sexual feeling which, in many instances, has previously been undetermined, and it may attain the intensity of imperative feelings. Psychologically, it is to be explained like the pathological association of fetichism and the impotence of persons of contrary sexuality.

Concluding Remarks.—A review of the cases already given, and of those still to be given in the therapeutic portion of this work, clearly shows the extraordinary importance of accidental factors of education and external influences in the etiology of paræsthesia sexualis,—a fact which, I think, is greatly undervalued by some authors.

We have seen that many cases that have been regarded by their reporters as abnormality of hereditary disposition were developed as a result of accessory causes; that the proof of the existence of a congenital predisposition, such as that of the female type of character in a male body, for example, rests entirely upon statements made by patients, and therefore is defective. The historical and developmental theory of anthropological transformation (androgyny and gynandry) seems to us least entitled to support by experience.

On the other hand, as a rule, pathological association was

capable of developing the evil results only where a nervous system of slight resistive power—the most frequent symptom of hereditary taint—offered favorable ground. The experiences with fetichists taught us, first of all, what part may be played by the object of the perversion, in determining its form as a cause of imperative ideas and feelings with their consequences (effemination, for example).

The part played by the accessory factor in the etiology of the habitual impulse to perverse sexual acts is usually more important than that played by hereditary disposition. And the latter, in the class of psycho-sexual anomalies we have considered, and which, in comparison with those resulting from demonstrable original brain constitution, includes the larger number of cases, represents a general pathological disposition (imbecility or irritable weakness), and a want of resistive power to compensate the pathogenetic excitations by normal opposing concepts or inhibition of impulse. With this, I think, we have reached a more general and a clearer conception of a large class of psycho-sexual disturbances and diseases, more satisfactory with reference to prognosis and therapeutics.

CHAPTER X.

DIAGNOSIS AND PROGNOSIS.

Remarks on Perverse Activity, Original Disposition, Accessory Causes, and Neuropathic and Psychopathic Symptoms. —Diagnosis in the case of fetichists and algolagnists is relatively easier than in the case of contrary sexuality; for, as a rule, their sexual power is associated with the perverse activity of the instinct, and normal intercourse is impossible. There are some exceptions to this. Perverse activity is to be regarded as pathological in every case where it is a *conditio sine qua non* of sexual power.

In algolagny, as pointed out in the foregoing chapter, it must be ascertained whether the acts expressing cruelty are active or passive in nature; also, when they are merely symbolic, whether they signify subjection.

Too, the abnormal manifestations of the sexual instinct largely arise from pathological intensification of the inclination, very common in healthy men, to experience variations in the sexual relations. In such cases the object and the manner of the perverse activity change; the object of it may belong to both sexes.

In all perversions, uranism as well as fetichism and algolagny, the question of hereditary taint, as shown by our considerations, must be studied most carefully. Therefore the following question is of the utmost importance. Is the perversion the result of an original abnormality of cerebral constitution, or has it developed as a result of accessory injurious influences of education upon the predisposing basis of a neuropathic hereditary taint?

Too, the states of original degeneration may become developed only in the course of life from the inherited disposition. In order to form a judgment of the "plastic capability of adequate adaptation to external circumstances" (Forel), the most exact knowledge of the accidental influences

of education is necessary. The occurrence of the first sexual excitement (indefinite feelings and erection), which may, as we have seen, take place as early as from the fifth to the eighth year, especially in those hereditarily predisposed; the external circumstances accompanying it, which often lead to the fatal association; further, the occurrence of the first sexual orgasm with its associated perceptions; and, finally, the ethical and emotional reactions,—all are of the greatest importance. Where, however, in spite of all favorable educational influences, and without demonstrable external causes, the perversion progressively develops, congenital disposition seems to bring about the result. Still, it must be remembered that the exciting causes are often forgotten. The idea accompanying the onanistic act (whether psychical or mechanical) should be studied, for by practice and habit the abnormal thought may become an imperative idea.

But the absence of onanism does not exclude cultivation. For the fancies accompanying dream-pollutions are likewise merely recapitulations of the individual's experience. If, in their first sexual association, these are of a perverse nature, they may then assume the *rôle* of cultivation.

Such cases, also, as those in which no hetero-sexual rudiments of any kind can be discovered are by no means decisive as evidence of the original character of contrary sexual instinct; they may likewise be the result of external influences which, from the first perverse association, completely appropriated the undifferentiated sexual feeling, and thus left no opportunity for other sexual feelings and experiences.

On the other hand, very important in establishing the original tendency of contrary sexual instinct is the proof that the feminine characteristics of the male child were developed before the occurrence of the first sexual excitement (not before puberty, as many urnings think), and that feminine sexual feeling arose from these characteristics without the aid of external influences. On this point, however, the statements of urnings—their confessions—are to be accepted only with great reserve. For, while writing the autobiography, these individuals are under

the subjective influence of a sexual development resting upon numerous experiences; perhaps, too, they are subject to the unconscious suggestion of von Krafft-Ebing's theory of heredity, and thus enlarge the history retrospectively, without distinction in time of the subjective events.[1] On this point, no error is easier than to date the beginning of effemination before the time of the first sexual excitement; while effemination as a secondary product of sexual inversion would speak in favor of the theory of cultivation. Standing alone, without sexual inversion, manifestations of effemination prove the existence of contrary sexual instinct as little as do physical peculiarities which resemble those of women.

We may distinguish three possible etiological developmental factors in the production of contrary sexual instinct: (1) original cerebral constitution; (2) a neuropathic disposition with educational influences; (3) pure cultivation in normal individuals. Class 2 is by far the most numerous.

In sexual inversion the following important diagnostic points should be considered: (*a*) the episodical occurrence of homo-sexual impulses in individuals of hetero-sexuality; (*b*) psycho-sexual hermaphroditism; (*c*) the content of sexual dreams; (*d*) the complete absence of hetero-sexuality as a pathological phenomenon (Moll).

It is of the greatest importance in diagnosis to demonstrate the existence of other neuropathic or psychopathic symptoms, signs of degeneracy, etc.; that is, to ascertain whether the perversion occurs as a symptom of moral insanity, congenital imbecility, etc., or whether the disturbance of the sexual instinct seems to be isolated and independent in an individual otherwise normal mentally.

Besides, there is also the question of responsibility. The fact of disease of the sexual instinct does not in itself render the

[1] Binswanger very justly expresses his mistrust of such "auto-suggestions of doubtful value"; for, in his opinion, they might arise especially in connection with the "amalgamation of abnormal sexual inclinations with increased physiological excitability." Nowhere, according to Binswanger, is there a greater effort to be excused morally and legally, and to cover with the mantle of abnormal constitution acts which are not in accord with modern morality, than in this domain.

individual affected irresponsible. Only the proof that the individual has committed a criminal act as a result of organic necessity, as if forced to it, and, owing to his cerebral constitution, was incapable to developing (or acquiring) the necessary inhibitory (or restraining) ideas, will allow him to be held as devoid of free will. Very many individuals of contrary sexuality are well able to control their impulses. The broad leniency which Moll accords such patients, in this respect, seems to me to be unjustified; and it could be misused as permission for the justification of the most vicious practices.

Further diagnostic details are given in the works of von Krafft-Ebing and Moll, and in the preceding chapter.

Dependence of Prognosis upon the Causes of Origin.— The development of the perversion depends upon the lack of a rational development of the mind and will. The abnormal congenital disposition to perverse activity of the instinct, since it must be regarded as dependent upon cerebral organization, can scarcely be removed by any remedial measure. Still, in this, the severest form of predisposition, properly-directed measures may be successful in hindering the perverse tendency; in preventing the premature awakening of the sexual instinct; and eventually in establishing normal sexual intercourse by artificial cultivation. In isolated affection of the sexual instinct the prospects of cure are better than in individuals of defective constitution (Binswanger).

If the form of the perversion is not predetermined by the organization, but developed by exciting causes on a neuropathic basis, a favorable prognosis may be given. For the result of education may, in its turn, be overcome by education. The general condition of the nervous system will determine whether merely improvement of a deeply-rooted malady or complete cure is possible.

According to von Krafft-Ebing, the occurrence of effemination in individuals of contrary sexuality is the limit beyond which there is no hope in therapeutics. The more closely the abnormal inclinations are united with the constitutional peculiarity of the individual, the slighter the prospect of lasting

benefit. But this question still seems to us an open one; increasing observations of the favorable results of suggestive therapeutics make it seem possible, perhaps, to bring about a relative limitation and diminution of the acquired feminine character. Psycho-sexual hermaphroditism, cultivated pederasty, and acquired contrary sexual instinct in untainted individuals offer prospects of complete cure. Also, hetero-sexual rudiments in homo-sexual individuals permit a hope of awakening normal sexual feelings.

The intensity of the impulse and the past duration of the condition must be taken into consideration in the concrete case; as well as irritable weakness of the genito-spinal centres, which is a frequent accompanying symptom. Thus, even degenerate individuals may possibly be benefited to a certain extent. Whether, however, the completely-developed delusion of sexual transformation, and likewise algolagny in its highest degree of development (necrophilia and lust-murder), can be influenced, seems questionable. But we are not justified in stating that there is no hope while no attempts have been made in such cases with hypnosis. In a developed psychosis, in accordance with present views, psycho-therapeutics can accomplish little; therefore, where sexual perversion occurs as one of the symptoms of a psychosis, an unfavorable prognosis is to be given,— as in epileptic pederasty, in the perversities of paretic dementia, and in those occurring in certain states of periodical excitement.

CHAPTER XI.

PSYCHICAL AND SUGGESTIVE TREATMENT OF SEXUAL PERVERSION.

Consciousness of Moral Duty as a Prophylactic, with Remarks on Education in Morals, from the Stand-point of the Theory of Suggestion.—The principal task in the prophylaxis of sexual errors lies in education. A good moral character is the best preventive of psychoses. For passions and vices exhaust the brain and alter its constitution. Through yielding to dissipation and want of self-control many an insane patient has been, in part, responsible for his disease. The importance of moral education for mankind is shown by the facts of heredity. Congenital pathological changes of the brain, however, cannot be influenced either by the whole armament of moral treatment or by other means. No form of education is capable of compensating for the congenital defect of ethical ideas. In such a case, the strict discipline of a well-conducted institution is indicated.

Apparent cures of psychical degeneracy, as they are occasionally reported, in case of correctness of diagnosis, are explicable as marked remissions such as occur in moral insanity. For, according to the agreement of all alienists, original psychical degeneracy is incurable.

As a rule, however, we have to do merely with predisposition to perverse actions, and here correct education and control of the impulse may bring about improvement. Concerning the degree to which temperament and character can be influenced by pedagogic means, there are various opinions. That instincts can be overcome there is no doubt.[1] Taking the idea of suggestion in its widest sense, all education may be regarded as a combination of co-ordinated and well-considered "suggestions." It does not, of course, consist of merely the

[1] Comp. Guyau, Education et Herédité, Paris, 1890. This book gives excellent remarks on this subject, but it seems to us to contain some errors concerning the conception and significance of suggestion.

teachings of parents and teachers; morality, religious faith, and related conversation and social intercourse have an effect on the brain that is to a certain extent latent, and thus direct our habits. But education cannot create genius, though it may develop it.

Moral health is more important than intellectual qualities for the progress of the individual and the race. Vicious moral instinct leads to deterioration and extinction. Therefore, the creation of moral duties may be regarded as the necessary object of individual development. The Darwinian selection of the useful, in social life of animals, for example, also leads to the development or predominance, even though in a broader sense, of minor capability or peculiarity, by sexual selection.

Our acts are directed by what we call "duty"; this is the result of morals and reflection,—the product of harmony brought about between our dominant inclinations and the formulæ that have been suggested to us by the influences of education. With children, it is sufficient to emphasize this or that good peculiarity that is found in them in order to induce them to develop this faith. Every lively image (idea) in consciousness strives to make itself real in acts. It is necessary to make the child believe that it is morally free and master of itself. The opposite of this is moral abulia, an active yielding to the first strong impulse. To give a child bad feelings, to blame it unjustly (compare Case 67), is to bring about the opposite result,—to point out evil and develop it. Often the child is not conscious of doing wrong. In such cases it is necessary to convince the child that it did not choose to act so, but did it in mistake. Just as with hypnotized subjects, it is necessary to presume the existence of the peculiarities we wish the pupil to possess. Among the most powerful means of suggestion are public respect and self-respect, since daily experience shows that this means alone is effective in improving individuals. The abandonment of evil ways, perhaps, at first through external influence, at last becomes a habit, and the simultaneous direction of the attention to good contributes its share to the modification of conviction. And in the same manner an inner transformation may likewise take place.

Suggestion is merely the introduction of a corresponding belief to be later realized; the effect of suggestion, therefore, consists of the art of convincing an individual that things are or may be different from what they actually are. Thus, it is necessary to convince children that they are only capable of good, and absolutely incapable of evil. The suggestions of early years are the most powerful of all. There are good and bad instincts in every human being; and it is only necessary to guard the child on occasion from receiving the formula for the evil instincts. The consciousness of evil inclinations, of perverse tendencies in the vita sexualis, as a rule, intensifies them. Therefore, urnings try to excuse and justify their passion, as we have seen, by the aid of the theory of uranism originating with Ulrichs. The educator must also awaken the conviction that the individual is capable of understanding his acts. To cause any one to believe that he is a fool and incapable of this or that act is to systematically cultivate foolishness. Self-confidence must be increased by assurance. Through independent solution of difficulties the child becomes accustomed to being able to do what it wills; to school its will. Unfortunately, self-confidence is wanting in many men, especially in neuropaths, as is shown daily in medical observation. Mistrust of one's self finally becomes complete inner powerlessness. The conviction that one is perverse as a result of original cerebral constitution undermines all resistance to sensual impulses. Indeed, too intense a feeling of deficiency may lead to complete moral paralysis and suicide.

Thus, the great object of education is to create a series of habits by means of direct persuasion, acts, imitation, and admiration. Parents and teachers have an intense effect upon children through example; for children always imitate the persons about them. And these should always stand on a moral plane above that of the child. A firm will, leaning to justice and goodness, impresses children; that which astonishes most the child imitates. Thus, merely the example of goodness may actually improve an individual. It is not mechanical obedience, as enforced by the disciplinarian, but conviction and introduction by means of authority that are the correct factors in educa-

tion. When education has been successful in creating good habits, it remains to awaken the belief that these habits are valuable.

Every occupation, every social condition, has an educational influence. It forces us to act in conformity with a general idea. Our conduct is always accommodated to social relations. By this means, also, our hereditary tendencies undergo modification. Regular occupation in a calling has a general moral effect. Want of occupation, on the contrary, removes the individual from the influence of many social deterrents and abandons him to his inclinations and hereditary tendencies. Therefore, in the education of a child, the idea of sociability should be inculcated as strongly as possible from youth up. The ideal of humanity must be to direct hereditary instincts. In the sense here described moral and social suggestions may prevent the formation of a fixed idea, no matter whether it be related to crime or perversion. Natures that have lost equilibrium frequently are wanting in altruistic feeling (*e.g.*, the complete absence of compassion in criminals). And if such a feeling were present, in only a rudimentary form, in such an unfortunate being, still education could develop it and thus restore equilibrium.

Well-organized and regulated suggestions are capable of repressing or favoring the effects of heredity, no matter whether they be imparted during artificial sleep or in the waking state. For nothing takes place in hypnosis that could not be done in the waking state, more or less perfectly, even though in a rudimentary manner. Suggestion, therefore, does not present any isolated and remarkable phenomena. We are all sensitive to suggestions; and social life may be regarded as a state of equilibrium maintained by opposing suggestions. The possibility of personal resistance to suggestion varies considerably in accordance with individual peculiarities. The suggestive impulse may be looked upon as an imperative feeling *in statu nascendi*, which to a certain extent, like a rebel battles with pre-existing intense inclinations, and seeks, at the moment of suggestion, to turn the whole mind in the direction of a fixed idea which more and

more impresses the brain. At first suggestion always induces a temporary emotion, which, by cumulative effect,—as in frequent hypnotic sittings,—becomes a habit in the individual. The effect of suggestions during our childhood extends throughout our lives. Thus suggestion is a means through which a passive organism seeks to equalize itself with an active organism. The state of credulity in a child is comparable with the lack of resistive power in the hypnotized individual. At any rate, everybody believes most thoroughly what he convinces himself of; and therefore auto-suggestions often offer the most effectual resistance to therapeutic suggestions. The ability to suggest finally becomes ability to assure. The deep tone of conviction has the greatest suggestive power. Those persons that seem to assure the most by gestures and emphasis are the best hypnotic operators. An energetic will operates upon weaker natures like a command, and awakens corresponding feelings. Without the expectation of a definite result, without faith in one's self, there can be no activity. Consciousness of action is, at bottom, nothing more than the belief that one acts. Even a doubt may disturb habitual reflex acts. Thus, conscious life depends, in part, upon a relation in which we stand with ourselves.

Virtue and moral consciousness are not inherited; we inherit only the disposition to goodness and right-willing, as we may that to cruelty; education is more powerful in morals than in intellect. Every man, during the course of his life, comes to formulate rules for his own conduct, which vary in accordance with tastes, preferences, habits, and needs. The criminal, like the philanthropist, is directed by constant rules which, at bottom, represent the theoretical formula of his conduct. In harmony with the manner in which the nucleus of the soul is stimulated in the child, moral consciousness is developed. Since practice precedes theory, it is an important principle in education to direct the acts of children in a moral sense, before fundamental principles are impressed upon them. It is best if, as Herbert proposes, children formulate rules for themselves from their own experience.

True morality can never be the product of heredity. It

only results from education, when our reason gains possession of us. Therefore, consciousness of a moral duty signifies consciousness of inner and well-considered knowledge which directs our acts, the presence of ideas which strive to become real by virtue of their own power, and the presence of feelings which, as a result of their development, have in view the well-being of fellow-beings.

Other Means for the Prevention of Sexual Errors.—If the principles of education here laid down and studied with reference to the theory of suggestion are important in general for the development of the character in the child, it is still much more so for neuropathic individuals, in whom the vita sexualis seems to be the *locus minoris resistentiæ*, and which, under the influence of unfavorable conditions, is directed into perverse lines. Sexual education, then, besides observance of the measures given in Section I, with careful watching must endeavor to delay as long as possible the appearance of sexual instinct, and to diminish its intensity as much as possible. Pathogenetic stimuli, as offered in seduction and example, are to be prevented. In order to prevent pathological determination, care must be taken that the boy is accustomed to the society of female companions. Noticeably close friendship with boys and indifference toward girls require the most careful watching by parents and teacher, and should arouse suspicion.

Especially in abnormal individuals, the will must be schooled to control sensual impulses. But the inculcation of moral principles, great as their worth may be, must not go to the extent of the ascetic development of abstinence physiologically unattainable. In one of my cases the opposite—love of men—was artificially induced. It has been previously mentioned that, at the time of puberty, a rational explanation of the sexual relations is a powerful prophylactic. Unfortunately, in most families, this point is overlooked. With a negligence for which there can be no excuse, the determination of this instinct, so important for procreation, is left to accident; hence the intractable undifferentiated sexual feeling, excessive onanism, and the cultivation of perversions. Ask such unfortunate

persons who has explained their malady to them, and it will be found that it is seldom parent or teacher, but popular books, friends, etc. I believe that, in severe forms of sexual perversion, help and cure are possible as long as the individual is still undergoing development. The earlier the individual treading a false path is treated, the better the prognosis. Where there is a certain amount of ethical weakness, or inability to form inhibitory ideas, an attempt should be made to associate such individuals with normal comrades possessed of strong wills, to whom passive natures easily accommodate themselves. Tarnowsky thinks that slight ridicule of boys that manifest a preference for female occupations may prevent the development of perversion. At least, it should be remembered that the activity of feminine inclinations cannot occur without some fault in education. In all these questions, as von Krafft-Ebing remarks, the family physician can give assistance and exercise prevention, provided his advice is sought.

Should Urnings be Treated?—A question of prophylaxis from the stand-point of coming generations involves the *pro* and *con* of the treatment of urnings. Moll[1] raises the question whether contrary sexual instinct should be treated medically; indeed, does not pederasty, according to Schopenhauer's view, serve nature's purpose, in that, as a vice, it prevents the begetting of unfortunate descendants by "old and sexually-depraved men"? Moll thinks that it would be possible to bring about disharmony in the pronounced effemination of an urning!

The writer mentioned does not feel justified in giving a positive answer to this question, but leaves it for social and legal determination.

Marriage.—I hold that, under all circumstances, medical treatment of such unfortunates is indicated as long as it is not attempted to carry it beyond impossible limits. That coming generations must suffer as a result is, as our study of the matter has shown, quite possible, but it is by no means proven. Besides, the union with a female character may compensate the peculiarity. Such individuals should be directed to marry emo-

[1] *Loc. cit.*, p. 209

tional women possessed of lively sexual desires. The opposing characteristics of the mother, in accordance with the law of inheritance, compensate the defect in the father, and thus the descendant more nearly approaches the normal standard.

Still, one must be aware that marriage is not a cure, for psycho-sexual hermaphrodites are not so infrequent among the married. Tarnowsky saw cases in which youths with "congenital sexual perversion," aged from 25 to 30 years, became capable of intercourse with women, married, and begat children. Moll doubts that these persons became normal. I think Tarnowsky is right; only they were not cases of original disposition, but perversions in predisposed individuals, induced by exciting causes.

Onanism and Exciting Causes.—Owing to the extremely injurious effect of onanism, which plays a part in almost all forms of sexual perversion, youths must be most carefully watched on this point, in accordance with the advice given in Section I (schools and academies). But the dream-life and pollutions at night must not escape attention. For in case of some pathological association with abstinence from onanistic acts, a dream-picture of perverse content with simultaneous pollutions, as a result of continued repetition, may assume the *rôle* of ideas accompanying masturbation. The abnormality of these ideas is the starting-point of psycho-sexual disease. They must, therefore, not be allowed to become the imperative product of habit.

Prophylaxis against the injurious influences described in Chapter IX is to be carried out in accordance with the peculiarities of each case, without any thought to make a general application of the measures here described. Thus, for example, in the case of a predisposed boy, spanking should not be practiced, if it induce sexual excitement, in order to nip algolagnistic inclinations in the bud.

The therapeutics of the anomalies of the sexual instinct, according to von Krafft-Ebing, may be advantageously divided into three parts:—

1. Treatment of the constitutional disease forming the

basis of the sexual perversion (neurasthenia sexualis or universalis).

2. Removal of onanism and other influences injurious to the vita sexualis.

3. Specific treatment of the abnormal instinct.

Antineurasthenic treatment, the means of which are sufficiently well known, under certain circumstances, is alone sufficient to cure cases that have made but slight progress. Besides hydro-therapeutic, electrical, and medicinal means, severe mountain-walks, extending over months, are especially to be commended. In addition to strengthening the constitution, they also strengthen the will.

The treatment of onanism is given in detail in Section I, and therefore we may omit it here, as well as that of sexual hyperæsthesia and impotence,—the most frequent accompanying symptoms of sexual paræsthesia.

In respect to the two points mentioned, almost all sexual perversions seem to us amenable to medical treatment; perhaps cases of advanced dementia are exceptions, as they are rather to be met with in asylums than in private practice.

Psycho-therapeutics in Cases of Perverse Instinct.—The treatment of an abnormal instinct can be only psychical. Where psychical treatment in the waking state is not successful, suggestion in hypnosis may be advantageously brought into requisition. In all cases the patient should be made to school his will, that he may thus be able to control his impulses. The patient should be advised, by energetically conquering himself, to think of woman and the sexual act, and in any sexual excitement attempt to substitute woman for man. Many patients are finally able, in the struggle with themselves, to experience pleasant feelings and erection in the thought of hetero-sexual relations. When this is attained the victory over the abnormal instinct is practically won.

In the process of recovery, every person of contrary sexuality passes through the stage of psycho-sexual hermaphroditism, —a condition in which he is excited by both sexes. What at first gives rise to the greatest repugnance (feeling of disgust) by

patient repetition finally becomes habitual; and many patients give the assurance that, in sexual excitement, they are able, without the slightest difficulty, to substitute female for male fancies. Some of the cases reported in the following series clearly illustrate psycho-therapy without hypnosis.

In the treatment of urnings, Moll correctly distinguishes two objects: (*a*) overcoming the instinct itself; (*b*) repression of its activity.

Of course, the first—that is, the removal of perverse feeling—is the more important. I agree with Moll's view that, on the whole, it is advantageous first to suggest hetero-sexual feelings until the patient himself feels the need to attempt coitus. That is the natural manner of cure. The performance of coitus, even when, in spite of repugnance and with the help of the perverse imagination, it is successful, is in reality no cure. Want of success, on the other hand, causes a feeling of depression and makes further treatment more difficult. From this is derived, as a fundamental principle of treatment, the combating of hetero-sexual feelings and the creation and promotion of hetero-sexual feelings; and, in the second place, the direction of the activity of the instinct in a normal way. Further, it should be remembered that in neurasthenics with perverse instincts weakness of sexual power is frequent, and that several months of abstinence essentially contribute to the restoration of the weakened sexual function.

Regulated Sexual Intercourse.—With complete acknowledgment of Moll's caution mentioned, regulated sexual intercourse seems to us to be advantageous where the instinct and effemination, or other perversion, are complete. It is very difficult, sometimes impossible, for example, in persons of fully-developed effemination, to induce by suggestion alone hetero-sexual feelings and ideas of such intensity that erections occur where the corresponding sensory perceptions are wanting to the patient. Cases in my experience, on the other hand, show me that patients who, in the first attempt at coitus, had feelings of disgust and were impotent, in the second, made on my advice, under the influence of alcohol, were successful; and in the third

attempt proved potent, even though erection was brought about only after manipulation by the puella. Thus the ice was broken, and the patient's sexual impulses were made harmless in spite of himself. Sexual intercourse, begun under such difficulties, must be regularly continued by the patient until it becomes a habit.

In patients that are not weakened sexually, finally spontaneous erections occur, and the psychical equivalent—that is, the psycho-sexual reflex effect—must occur. Whether this completely compensates the perverse tendency depends upon the degree of the malady and individual conditions. A diminution of the abnormal ideas takes place, however, in all cases. Thus, Binet also observed, in fetichists, that from the moment of regulated sexual intercourse the image of the fetich paled and lost its harmful influence. For abstinence from natural sexual congress induces sexual hyperæsthesia and intensifies the impulse in its perverse direction. Conversely, inclination for women may arise from regulated coitus. Indeed, I have observed that the patients were able to resist homo-sexual temptation as long as intercourse with women was continued; but as soon as a long pause occurred, the impulse, *faute de mieux*, took its old direction.

The relapses noted in my patients occurred at a time when they were abstaining (illness, absence of the physician, long absence of the wife, etc.). In few severe cases will it be possible to obtain a relative cure in this way. In severe cases,—for example, in well-developed effemination,—at least, it will be possible to bring about a compensation of the perverse instinct in sexual relations. The patient regains his inner equilibrium, and at last finds himself in the desired situation. In occasional relapses he finds no pleasure in homo-sexual relations. Moreover, in many patients the occurrence of imperative sexual ideas of perverse content corresponds with their physical condition. Deterioration of bodily health goes hand-in-hand with the recurrence of homo-sexual images. Not every case of psychical impotence in sexual perverts has its cause in perversion of the instinct. Rather, there are also neurasthenics in whom

virility alternates with impotence periodically, as does depression and exaltation. Such neurasthenic impotence may also exist in individuals of contrary sexuality without the causative influence of the abnormality of the instinct.

But the transformation of the sexual feeling is not without effect on the character. In one case I observed that there was an increase of self-confidence and energy, the want of which was previously characteristic of the patient's malady; these characteristics were influenced by duties of occupation which called all his manly powers into requisition. In one case of complete effemination, likewise, there was an unmistakable weakening of feminine peculiarities. Powder and paint were no longer used; the pictures of urnings disappeared from the wall; the feminine articles of toilet were given away; and in some situations the patient's conduct was much more decided; and, besides, a certain diminution of inner lack of control was noticeable. Still, as before, there was interest in men, though it was not much colored sexually.

Tarnowsky also confirms the great importance of regulated sexual intercourse. He says:[1] "With continuance of sexual intercourse, especially with the same person, the sexual perversion gradually weakens; and, finally, the youth, who from birth was disposed to perverse sexual activity, becomes a man with normal sexual functions, capable of family life."

Suggestive Treatment in Hypnosis.—With most patients, energetic advice—that is, the psycho-therapeutics of the waking state—is not sufficient; and it then only remains to make use of hypnotic suggestion. Von Kraff-Ebing regards it as the only "means of salvation" in desperate cases. Where rudiments of hetero-sexual feeling are still present, these must be strengthened by suggestion; where they are wanting, the hetero-sexual feeling must be artificially created. In suggestion, as the writer mentioned justly remarks, we have an excellent means with which to destroy the abnormal psycho-sexual existence and create a new. Whether, however, as von Krafft-Ebing thinks, a deepening of hypnosis to somnambulism is necessary for this,

[1] *Loc. cit.*, p. 18.

The certainty of this manner of observation and the careful report of relapses, which are seldom to be met with in other branches of therapeutics, justify us in drawing almost certain conclusions from the material at hand concerning the prospects of cure in cases of sexual paræsthesia. The probability of success with suggestion may be expressed as 70 per cent., that of cure as 34 per cent.; but, as a rule, one should prepare such patients for the necessity of prolonged treatment. In one case one hundred and forty-two sittings were necessary, and in another two hundred and four. Too, it may be recommended that, in order to make the cure lasting, the patient should, as a prophylactic, be hypnotized once every week or two for a year after the cure has been established, and care be taken that sexual intercourse be practiced regularly. It should always be remembered that the period of treatment for confirmed habits is dependent upon the time required by the perversion for its full development.

Too, in the severest cases, as we have seen, it is possible to remove onanistic inclinations and sexual hyperæsthesia. In cases of contrary sexuality, as a rule, after a certain period of treatment a state of sexual neutrality is established, in which the patients have become indifferent to homo-sexual charms, but are still insensitive to women. With the beginning of regulated normal sexual intercourse, which, in my opinion, is the *conditio sine qua non* of cure, the feelings of disgust, present at first, gradually disappear entirely; the fancy of the patients becomes more and more impressionable and excitable to feminine charms, and in the transitional stage of psycho-sexual hermaphroditism care must be taken, in external circumstances, that the product of suggestive cultivation gradually compensates the deeply-rooted inclination. The mental rudiments grow more and more indistinct, and only cause relapses where occasionally sexual impulses, unsatisfied in the normal way, gain a renewed mastery over the individual and, to a certain extent, furnish new material to the old inclination, whether this be homo-sexual, algolagnistic, or fetichistic in nature. If, as we have previously tried to show, effemination is a secondary manifestation of homo-sexuality, then, logically, the sexual transforma-

tion, in the sense of a male-feeling individual, cannot take place without affecting the mental life of the individual concerned, even though it must also be admitted that such secondary changes of character, in the sense of weakening, are perhaps only fully developed in the course of years, and always require long periods of time. The theory of contrary sexual instinct and its possible cure is still too young to allow a judgment of it in this respect, based on practical results.

When, in case of contrary sexual instinct, cure is spoken of, it is to be understood only as a relative cure. For absolute cure would presume complete removal of the homo-sexuality, its *memory-pictures*, and a physical reflex effect of them which occurs episodically in many patients. This, however, is not within human power. One may be satisfied if these pictures fade and become innocuous rudiments, and if the sexual life is led into the path of regular and natural activity.

If we have been successful in demonstrating that this therapeutic result, so important for the life of such unfortunates, may be obtained by suggestive treatment; that useful members of society can be made of such perverted individuals,—then the object of this work has been attained. May it contribute to the success of the struggle with this dark side of our social life, and open to workers in the domain of suggestive therapeutics a new and productive field of activity and humane striving!

APPENDIX.

PREPARED FOR THE ENGLISH EDITION IN OCTOBER, 1894; TRANSLATED FROM THE AUTHOR'S MANUSCRIPT.

THE studies in the pathology and therapy of psycho-sexual anomalies contained in the foregoing work were published in the German for the first time two and one-half years ago. Though, during the period that has elapsed, many new and important additions have been made to the question of sexual perversions, and though views opposed to those advanced by the author have not been wanting, still the contents of the book have retained the value at first attributed to them. The purpose of this appendix is, therefore, the addition of some not unimportant supplements to several of the sections, as well as to a number of histories. The following notes are arranged in accordance with the chapters of the book, and are made as brief as possible.

Case 14, Section I.—Since this patient was discharged three and one-half years have passed. At first the patient remained cured as long as he had opportunity for sexual intercourse; however, when for any reason this was not possible, he masturbated, but during two years he did not do this more than three or four times. During the last year and a half this has not occurred. He attends to his calling and feels himself perfectly well.

Case 15, Section I.—In the meantime the patient has become a physician and follows his calling without further need of medical help.

Case 18, Section I.—During the two years and a half since discharge, the patient has remained well; a visit to her home convinced me of this. She has now been happily married several months. This case, which has now been under observation more than three years, may be regarded as one of the most brilliant examples of the efficacy of suggestive therapeutics.

Case 20, Section I.—This patient has remained cured during the two and one-half years that have passed. She resumed her calling and removed to another city. The last written report was received three months ago.

Case 35, Section II.—In June, 1894, two and one-half years after discharge, this patient visited me again to express his thanks that the mental treatment in 1891–92 had put him on the right road to recovery. The patient is happily married, and already the father of one child; he has made himself independent, and may be regarded as definitely recovered.

Case 37, Section II.—As may be seen from the text, after remaining well two years, in October, 1891, as a result of severe nervous trouble the patient had a relapse, but fortunately he came under my treatment immediately again. A few hypnotic suggestions again restored his virility, and he has remained well.

Case 38, Section II.—In November, 1892, the patient again presented himself and desired to have the hypnotic treatment resumed, though the success of the previous treatment had been lasting, mainly with a view to have it become more stable, —in reality, through fear of a possible relapse. Twenty-two additional hypnotic sittings. At the first coitus during the period, erection by means of manipulation by the puella; then slight emission. On the other hand, on three other occasions the patient had intercourse with complete satisfaction. On November 27th the patient went home with the re-assuring consciousness of complete virility.

Case 62, Section III.—Since this patient was discharged nearly four years and six months have passed. As I ascertained by a personal interview with him, in the interval he has become the happy father of three healthy children, whom he is educating carefully, and whom he observes with a view of a possible existence of any hereditary disposition. As long as R. remains with his family and is required to lead a regular life in the small town where he lives, he feels perfectly normal and balanced. He is bound by love to his wife and children, and his sexual functions leave nothing to be desired. Occasional

homo-sexual importunities, as on meeting former friends, he successfully withstands. However, if R. be on a journey alone for any length of time, which occurs perhaps once a year, he still finds pleasure in homo-sexual practices; but this is not from an irresistible impulse, nor from a love of the male sex or of any man, but to excite his nervous system by the enjoyment of forbidden fruit. Therefore, in this case, we have to do not with an abnormal impulse, not with a relapse, but with the induction of new and exciting sexual situations from pure sensuality, wherein, however, the re-awakening of sensual memory-pictures from the past plays an exciting and intensifying, though not determinate, *rôle*. The acts which five years ago indicated desire of the sexual instinct have now become simply acts of vice.

Case 63, Section III.—One year after the appearance of the foregoing work in Germany,—that is, about three years after the beginning of treatment,—I received the following report from the patient:—

March 22, 1893.

Honored Baron: In meeting your wishes by writing you a few lines concerning my health, I must think what I have to write,—so thoroughly have I become accustomed to my new life. I have intercourse regularly with women, but it is only within the last few months that it has been regular, since that with prostitutes gradually became repugnant to me. What I formerly regarded as impossible, and what *a priori* I was forced to repel, I now entertain. I am thinking much of marriage; I imagine myself married; long for children and a family; and I think I should make a good, too good, father.

I have no erotic fancies, since libido has greatly decreased; the accompanying symptoms of the former disease—migraine, depression, and anxiety—have entirely disappeared, so that I am now in a stable emotional condition, and I could be entirely satisfied were it not for my past. This, however, constantly comes up threatening, and to my fear of it is added disgust and repugnance of myself and my former acts, such as a normal man must always feel for contrary sexual persons. The memory of this frightful, debasing period will probably always poison my life. Always obligated to you, honored Baron, in deepest gratitude I remain, Respectfully, A.

Since the receipt of this report one year and eight months have passed, and during that time the patient has kept me in-

formed at long intervals concerning his condition. To-day A. feels masculine; neither in his sexual nor in his psychical condition during this time has he relapsed, but he has intercourse regularly, and has a horror of sexual acts with his former companions. The symptoms of effemination have all disappeared, as have all the neuropathic troubles; his appearance is healthy (brown complexion); his manner shows more certainty and assurance; his energy has increased and has withstood many trials successfully. This latest verbal report I have no reason to doubt; the more because of the patient's demonstrated love of truth, and because his whole physical condition corroborated his statement. A. has now been under my observation five years without relapse in the last three years. Certainly the most careful skeptic would allow the justice of regarding this patient as cured. This case, on account of a complete effemination, is the worst case of contrary sexual instinct that has ever been reported cured; at the same time, no case where cure has been reported has been so long under observation.

Case 66, Section III.—One year after the appearance of the German edition of this work, or two and one-half years after the beginning of treatment, I received the following letter from this patient:—

March 1, 1893.

Honored Baron: A full year has now passed since I ceased your treatment. I am delighted that I can give you a most satisfactory report. I got on so well that I soon forgot what a sad condition I was formerly in, and I no longer thought of giving you a report. Since I left you I have continued intercourse with women unchanged. Gradually I felt increasing assurance, and in the whole period it occurred but once that erection was not so prompt and spontaneous as usual. In this instance I attribute the failure to great fatigue. While, during the first months, I sought women only because I thought I should, now I require no such stimulus; on the contrary, coitus always gives me intense pleasure. In proportion as pleasure increased, the memory-pictures of former times became less distinct. I have often had occasion to come in contact with men whose appearance would formerly have immediately inflamed my passion; now I can be associated with them without feeling the slightest excitement. The following seems to me worthy of special note:—

In May I fell ill with rheumatism, and part of the time here and part of the time at home I was in bed till the end of June. Until my

return to Munich, toward the end of August,—during convalescence,—circumstances denied me all possibility of coitus. During this time I was undoubtedly more excitable than usual; but, notwithstanding this, a meeting with a former friend left me entirely cold sexually, though otherwise I thought much of him. I was, at the same time, as little disturbed by the sight of attractive forms; I remained completely cold-hearted. Briefly, the transformation in my entire manner of feeling is so marked that I formerly should have regarded it as impossible. In the future I hope to be able to give you as good a report. With expressions of constant gratitude, I remain, Respectfully, H.

Since the date of this letter one year and eight months have passed; or, since the beginning of treatment, *four and one-half years*. Some weeks ago (September, 1894) the patient passed through Munich on his wedding-journey and visited me. My expectation that at that critical moment H. would require renewal of treatment was entirely uncalled for. H., on the contrary, seemed to be lastingly cured, and had not had *a single relapse*. Intercourse with his young wife was successful without the help of contrary sexual ideas. He loves his wife dearly, and their sexual relations are perfectly normal. Besides, his outward appearance is that of blooming health and manliness. The patient's brother, who is acquainted with his entire sexual life and who observed his transformation, confirms H.'s statements. I am also justified in regarding this patient as completely cured.

Case 67, Section III.—Soon after the appearance of the German edition of this book (summer of 1892) this patient discontinued treatment, notwithstanding the fact that the improvement obtained justified a favorable prognosis as to cure.

Impelled by unfortunate circumstances of business and finances, in the fall of 1892, the patient carried out the idea he had long entertained, and brought his unfortunate life to an end by shooting.

Case 68, Section III.—The restoration of this patient by suggestive treatment has not been undertaken because business circumstances have not allowed him time for treatment. In December, 1893, he informed me also that he was convinced of the hopelessness of his condition (a belief with which I cannot agree). He states that he has never been successful in the

onanistic act; at the same time he is doubtful about marriage, because of the possibility of tainting descendants. Led by reading Moll's work, he forced himself to entertain heterosexual fancies. In his opinion this led only to neurasthenic troubles. He continues: "In contrast with all this I have the greatest desire to have a family, but I must accustom myself to the inevitable. I repeat what I told you verbally,—that I suffer most from this deprivation, while the contrary sexual feeling *per se* and the necessary abstinence cause me no trouble. Apparently this is due to my moderate sensuality, which is satisfied by the sight and occasional hand-pressure and touch of the party in question. My general condition is good; there is no trace of neurasthenic trouble," etc.

Thus, my conclusions reached in this case in the text are still justified.

Case 69, Section III.—The sexual condition of this patient became perfectly normal through regulated sexual intercourse, as he informed me some years after discharge. To-day he is happily married and the father of several children.

Case 70, Section III.—This patient died, one and a half years after the appearance of the German edition of this work, of tuberculosis; and he never fully recovered, in the interval, from the effects of the influenza mentioned in the text.

Concerning the cases in the text not mentioned here, it has been impossible for me to obtain later information.

Numerous new cases likewise confirm the author in the correctness of the etiological and therapeutic deductions of the text. However, von Krafft-Ebing,[1] though the ninth edition of his work has already appeared in German, has not changed his views, but has sought to strengthen his theory of herditary taint by embryological and anthropological facts. Thus he recalls the original bisexual nature of the human sexual glands with the related sexual organs, and also that the beginning of

[1] Von Krafft-Ebing, "Zur Erklärung der Conträren Sexualempfindung," Jahrbücher für Psychiatrie u. Nervenkrankheiten, Bd. xiii, Heft 1.

development in a mono-sexual sense takes place first at the end of the third month of fœtal life. Too, in accordance with von Krafft-Ebing's hypothesis, the spinal and cerebral centres standing in relation with the sexual organs must also embryonically be possessed of a bisexual nature (?). Half of this embryonic possibility becomes latent; normally the other half, corresponding with the sexual glands which attain development, develops fully. In the male, the residua which indicate the original ontogenetic and phylogenetic bisexual possibility are the Müllerian ducts, the utriculus masculinus (vesicula prostatua); in the female, the paroöphoron as the remains of the original nephritic portion of the Wolffian body and as the analogue of the male epididymis. Under pathological conditions, the author (von Krafft-Ebing) assumes the virtual continued existence of the hypothetical cerebral and spinal centres corresponding with the latter, as a result of imperfect inhibition of them, which may even be of such degree as to allow active exercise of their influence upon the production of the physical and psychical sexual characteristics,—indeed, in infrequent cases, deposing the former from their normal domination, and leading to the development of a sexuality corresponding with the latter centres and out of harmony with the sexual organs.

The correctness of this new and ingenious hypothetical explanation can only be allowed after the existence of rudimentary spinal and cerebral centres has been anatomically demonstrated. However, the psycho-sexual condition of hermaphrodites, which von Krafft-Ebing also seeks to use as a support for this view, speaks much rather for an opposite opinion,—namely, for the great importance of exogenous factors. Laurent,[1] in his latest work, collects all the known cases of hermaphroditism, and, concerning the determining *rôle* of education in the sexual life, expresses himself as follows: "In many cases education is capable of forcing the sexual instinct in a direction opposed to that which should be taken, and of producing thus a kind of sexual inversion." On the whole, however, he regards such cases as degenerates of inferior mental endowment, who much more

[1] Laurent, Les bisexués. Paris, Carré, 1894.

frequently become the victims of vice and prostitution than of love; the majority are, in his opinion, indifferent from a sexual stand-point. The same author designates those men as gynæcomasts whose sexual organs have not attained complete development. As the only bodily attribute of the female, they possess feminine breasts. While in conformity with the anthropological transformation, according to the theory of von Krafft-Ebing, one would be led to assume at least the existence of a partial inversion of the vita sexualis in these cases, Laurent gives a number of detailed observations in which the sexual life was entirely developed in a masculine direction; and the observations of the author (von Schrenck) of bearded women and of men with feminine breasts are in entire accord with those of Laurent. Laurent questioned all gynæcomasts that came under his observation concerning their vita sexualis.

In spite of their emphatic denials, and without any certain proof, Laurent presumed that but two (!) of them had inclinations to sodomy (p. 97). From this the occurrence of an invariable or frequent correspondence of feminine physical characteristics with feminine sexual feelings in the male, and the opposite in the female, must be regarded as in nowise demonstrated. With each single case that speaks in favor of it, similar cases with an opposite psychical condition may be brought in contrast. The determination of this question will depend principally upon the embryological and psychological conception of the sexual instinct.

Meynert,[1] in his clinical lectures (not cited in the text), expresses himself on this point as follows: "There is little sense in assuming an inborn tendency with peculiarity of organization that leads to the idea of a female soul in a male body or a male soul in a female body. Instincts (impulses) are in no sense the result of our brain activity, but merely words. There is a feeling of hunger, but no instinct for food. In the feeling of hunger the child has no notion of the means to still it; it leads to death, or the child is suckled. Then the sucking-reflex acts, and the child experiences the sensation of satisfied hunger with

[1] Klinische Vorlesungen über Psychiatrie. Wien, Braunmüller, 1890.

which the act of sucking is associated, which now becomes a cortical movement, associated with the feeling of hunger, the odor of the nipple, and the taste of the milk. Where, between reflex and cortical movement, lies the third factor—the instinct —a congenital idea? There are tactile sexual sensations arising from the corpora cavernosa, but no inborn instinct in them. The influences which from them develop sexual activity are occasional perceptions, tradition, imitation, but never any congenital ideas, and, therefore, never any congenital anomalies of thought." Meynert was also always able to prove the exciting cause of contrary sexual feeling in his patients.

While Moll,[1] in the second edition of his work, emphasizes still more the theory of hereditary taint of von Krafft-Ebing, and regards our demonstration as weak,—a new *capitatio benevolentiæ* for the numerous homo-sexual individuals,—Eulenburg,[2] in a recent publication, however, declares that in the future, in the judgment of such patients, the exciting and accidental factors and their influence upon development will require more careful investigation than has heretofore been used. He holds it unproven that such factors can alone lead to contrary sexual feeling. On the other hand, in the precocious awakening of the sexual instinct, Eulenburg sees a clear indication of the presence of pronounced contrary sexual instinct. In opposition to this, as has been emphasized in the text, the neuropathic taint present in such persons, which allows the premature awakening of the sexual impulse, but without reference to its object, is to be taken into consideration. In the abnormal neuro-psychical taint, or, better, weakness, which Eulenburg regards as a *conditio sine qua non* in all these patients, also lies the impossibility of correction by means of later opposing perceptions of the sexual life. My explanations, which rest upon the psychological (folk) origin of uranism and upon pathological association, which my opponents allow in fetichism, have not as yet been vitiated by either Eulenburg, Moll, or von Krafft-Ebing. The fact remains unchanged: "Through exogenous

[1] Die conträrie Sexualempfindung. Berlin, Kornfeld, 1893.

[2] "Neuropathia sexualis virorum," Klinisches Handbuch der Harn- und Sexualorgane, Abth. iv, 1893. Leipzig, Vogel.

stimuli and perceptions the content of such sexual imperative feelings, or ideas, are supplied to such tainted persons, and through these a complete sexual transformation may take place."

Eulenburg designates paræsthesia sexualis as parerosia, and correctly concludes, from his premises, that a transformation of the pathological homo-sexual condition to a normal hetero-sexual condition is not artificially possible. My three cured cases (62, 63, 66), observed almost five years continuously, prove exactly the opposite. However, Eulenburg speaks warmly in favor of psychical treatment by suggestion. Appreciation and sympathy with such patients are necessary for the attainment of decided effects. From a number of recent cases the author (von Schrenck) is forced to regard the establishment of regular sexual intercourse as the principal requirement for cure. In cases in which, out of repugnance and whim, such patients did not fulfill this requirement, no deep and lasting success could be attained. The favorable reaction of hetero-sexual relations upon the mind of these patients, even though had at first without marked feeling of pleasure, was very seldom wanting. There are infrequent exceptions, as in persons devoid of lively sexual impulse, or in those that are more than 40 years old. But even in such individuals sometimes the dream-life is lastingly influenced. The dream-pictures accompanying occasional pollutions take their subjects rather from mental associations, strengthened by habit and deepened sensory impressions from the past, than from the weaker (so to speak) and purely theoretical influences of verbal suggestion.

Among the authors that have accepted the etiological explanation set forth in this work, Kräpelin[1] should be mentioned first. He is in accord with the writer in this, that the abnormality in the so-called contrary sexual feeling resting upon hereditary taint depends upon the peculiar impressionability of the prematurely-awakened instinct, which in turn depends upon the degeneracy. Through this the youthful sensibility is lastingly influenced by the first excitation of sensual feeling. In

[1] Psychiatrie, 4te Aufl., Leipzig, 1893, p. 691.

accordance with this, the prognosis in such cases is the more favorable.

Without reference to our etiological explanation, following Meynert and Binet, and published in 1892, Sioli,[1] in 1894, in an article on perverse sexual instinct, expresses the same view. "There is the same weakness of judgment, of association, which we conceive from an anatomico-physiological stand-point, as (1) a deficiency, (2) a weakness, of the association-paths, as the foundation of all cases, which we are accustomed to designate in common as hereditarily degenerate, as predisposed; in all these cases the perverse impulses arise only as a result of the circumstance that with the increase and union of memory-pictures the normal correction, the influence upon thought and action of the subsidiary, inhibitory, and opposing ideas, by means of the association-paths present in normal persons, are wanting, because these paths in these cases are absent." Thus, according to Sioli, arise the abnormal manifestations and acts which have led to the assumption of abnormal instincts, while, in fact, the cases are no more than instances of mental weakness and inability to correct the association of external impressions which determine all acts. As a result of the weakness of psychical association, the bodily sensations enter into consciousness—that is, into general thought and feeling—in a greatly-intensified degree.

The organic sensations arising from the sexual organs, in those patients afflicted with a weakened associative system, early exercise a powerful influence. As a result of these sensations, at first indefinite, arise handling and onanistic manipulations.

Accidental circumstances become associated with the sexual stimulus. Then, as soon as the pathological impulse has become a habit, the individual, as a result of his weakness of association, is incapable of attaining to an understanding of the normal relations with woman. Sioli finally very justly calls attention to the symptom of fallacy of memory, which is likewise explained by the weakness of association,—a symptom that, for the most part, has been insufficiently considered.

[1] "Ueber perverse Sexualempfindung," Zeitschr. für Psychiatrie, 1894, Bd. 1, Heft 5.

Geill[1] takes a middle ground. He fully allows the importance of injurious sexual influences in neuropathic individuals during development. However, according to him, such influences have no significance in congenital contrary sexual instinct. Such individuals exhibit a congenital weakness of the vita sexualis,—indeed, often of the entire feeling.

For the perverse manifestations of the sexual life included by von Krafft-Ebing in the terms *sadism* and *masochism* Eulenburg has adopted the word *algolagny*, suggested by the writer, in his work previously cited. As a reason for this, Eulenburg rightly states that the active commission of painful acts for the purpose of sexual gratification is in no sense characteristic of the stories of the Marquis de Sade, and that the passive *rôle* is as little so of the heroes and heroines of the novels of Sacher-Masoch. Besides (and in this I agree fully with Eulenburg), the acts of sexual cruelty are by no means exhausted by the active and passive *rôles*. In opposition to the terms used by v. Krafft-Ebing, the writer would remark that this manner of sexual gratification is much older than the works of Sade and Masoch, and that it has played an important part in history (*e.g.*, in the Church), especially in ancient history. Moreover, there is an *onanistic algolagny*, which I have lately had opportunity to observe, and under which many cases of auto-flagellation are to be classified; further, a *visual algolagny*, *i.e.*, sexual excitement at the sight of punishment; and a *zoöphilia* and *bestial algolagny*, as soon as the lust for cruelty is related to animals. Where there is merely the intensification of such a scene, the condition could be called *symbolic algolagny*. The violation of corpses, in this sense, when maltreatment of the body was associated with it, would be *necrophilic algolagny*, and it would be differentiated from simple necrophilia in that the latter, as the word signifies, includes only caresses of the body. Further, I have had opportunity to observe cases in which the pain *per se* played the principal *rôle*, without reference to its active or passive nature. Such patients are *algolagnists* in the true sense.

[1] "Die Lehre von der Psychopathia Sexualis und ihre gerichtsärztliche Bedeutung," Ugeskrift for Lägert, R. xxvii, Nr. 27–33.

Moreover, the tyrannical feeling of absolute mastery or of complete subjection, which von Krafft-Ebing regards as characteristic of sadism and masochism, is by no means always combined with algolagny, and therefore it can in no way be used to determine the condition. So much for the strengthening of the term proposed.

On the question of the responsibility of sexual perverts, in Section III of this work the view was expressed that the isolated existence of perverse manifestations of the sexual instinct gave rise in no sense to irresponsibility. This statement, further emphasized in Chapter X, has received new support in the excellent expositions of Sommer[1] concerning criminal psychology and penal laws. According to his view, the proof of the endogenous nature of a certain mental state is not sufficient to establish the existence of mental disease. He extends this thesis especially to the domain of psycho-sexual anomalies. According to Sommer, when it is proven that a person, from endogenous disposition, is perverse,—*e.g.*, when a man is excited (sexually) by another,—he should be punished for a corresponding act when the act falls within those that are punishable. "Human society has the same right," he continues, "to demand control of the endogenous impulse in general that it has to demand it in cases of congenital allo-sexual instinct when it is directed against a child of the opposite sex; or that the impulses to possess the property of others be repressed. Therefore, if these perverts are to be made free from punishment, this is not to be done during the existence of the present laws by declaring them insane, but by changing the laws. The decision of this question is not to be made by psychiatry, but by public opinion, in so far as it may be the expression of the actual moral will of the great majority of the people. As long as the moral ideas of the majority of the people are opposed to homo-sexual acts and the laws give expression to these ideas, the so-called contrary-sexual persons must control their impulses, as the man who, hungry, must control his impulse to possess

[1] "Kriminalpsychologie und Strafgesetzgebung," Deutsch. Medicinalzeitung, Oct. 10, 1894, p. 890 *et seq.*

himself of the property of others. At most, it might be said that the gratification of homo-sexual inclinations was a private matter between two persons, which does not harm society as long as scandal is not excited by it. There seems to be no doubt, however, that among those persons that indulge in homo-sexual acts there are many insane individuals."

According to Sommer, endogenous antisocial impulses (among which those in question are to be reckoned), like endogenous instincts, should not be punished, but they should not be taken as evidence of insanity.

The notes in this appendix in all respects confirm and enlarge the facts published in this work two years ago. The principal task of further investigation must be the publication of additional observations, in order to decide definitely the question of congenital contrary sexuality and other varieties of perverse sexual feeling in their psychological, pathological, and forensic aspects.

TO

DR. LIÉBEAULT,

OF NANCY,

IN ADMIRATION OF HIS GENIUS,

THIS BOOK,

THE OUTCOME OF HIS TEACHING,

IS GRATEFULLY DEDICATED

U630

PREFACE TO THE FOURTH EDITION

THE large third edition of 'Psycho-therapeutics' having been exhausted, and the book being out of print, I am asked to issue a new edition.

During the ten years which have elapsed since the former edition, the practice of hypnotism has made satisfactory progress; and I think one may say it has now taken its proper place as a recognised form of medical treatment. A good deal of new material has been added, and I have endeavoured to make the book as practical as possible.

C. L. T.

88, PARK STREET,
LONDON, W.,
March, 1900.

PREFACE TO THE THIRD EDITION

THE fact that the second edition of 'Psycho-therapeutics' was exhausted within two years of the first appearance of the book affords at once an indication of the interest with which hypnotism is regarded, and a justification for the issue of a new and larger edition.

The increased size of the present volume is due to the wish many persons have expressed for a book dealing more fully with the theory of Psycho-therapeutics, and it is hoped that the additional matter will be found to throw some light on the subject.

I have endeavoured to treat the question with fairness and frankness, and I shall consider myself well rewarded if I have succeeded in putting it before my medical readers in such a shape as to induce them to make trial of hypnotic suggestion.

I have again to thank Dr. Habgood for his kind assistance in preparing this edition.

C. L. T.

LONDON,
October, 1891.

PREFACE TO THE SECOND EDITION

In bringing before the profession a second edition of 'Psycho-therapeutics,' I must thank my critics for the kindly manner in which they received the book a few months ago. It professed merely to be an introduction to the subject, and it seems to have fairly well fulfilled its purpose.

The present edition, while claiming only the modest position of its predecessor, is considerably enlarged, and contains additional chapters on the physiology and psychology of hypnotism, on simulation, and on my personal experience, which will, I hope, render it a useful handbook for practitioners who have not the time to devote to more elaborate and systematic works.

Dr. William Habgood has kindly assisted me by revising the proofs.

C. L. T.

January, 1890.

PREFACE

In bringing forward this little book on Treatment by Suggestion, I feel that, though I must crave indulgence for the shortcomings of the writer, no apology is necessary for introducing so important a subject.

The Nancy treatment has during the last few years attracted so much interest among men of science and members of the medical profession on the Continent, that it seems strange the knowledge of it in this country is almost entirely theoretical. The system of psycho-therapeutics has so far attained its fullest development in Holland, where in every large town it is followed by at least one well-qualified practitioner; while in Germany, Russia, Sweden, and, indeed, every European country, its position is secured by the support of leading physicians, and by the success attending their practice. In every country, I believe, the introduction of the system was at first opposed by persons who feared the popularization of so potent an agent; but as the beneficial results of the treatment became manifest opposition decreased, and has now almost died out. This is doubtless due chiefly to the fact that the treatment has not been allowed to fall into the hands of ignorant and unqualified practitioners, but has been accepted by men of high character and professional repute. The dangers of hypnotism have been proved chimerical: in proper hands no undesirable medical results can occur through its practice, and there is, I believe, hardly one authenticated case of its being used for a criminal purpose in the countries

where it is most frequently employed by medical men. More than this can hardly be said for any system of medical treatment.

But while maintaining that hypnotism has been very little used for criminal purposes, we should be foolish to blink the fact that it *might* conceivably, under certain circumstances, be a dangerous weapon in unprincipled hands, and that its injudicious use *might* lead to physical and mental ills; but such evil results are in a very great measure preventible. Wherever hypnotism has been largely adopted as a valuable aid in the treatment of disease, its importance has been formally recognised, and its employment by charlatans, either as a toy at public exhibitions, or in unauthorized medical practice, has been prohibited by law.

Medical electricity is only now emerging from the limbo of quackery, because for years the medical profession allowed it to be exploited by 'professors,' who used it as a universal remedy in all cases, suitable and unsuitable. The Nancy system has been successful on the Continent because it is practised there by qualified physicians and surgeons, whose knowledge and experience has taught them where the treatment would be likely to succeed, and where it would prove ineffectual. I here advocate its use not as a universal remedy or as a supplanter of ordinary medical treatment, but as a powerful auxiliary in combating many forms of disease not readily reached by other means.

TREATMENT BY SUGGESTION

CHAPTER I

INTRODUCTION

It is desirable to set forth clearly the genesis of the present revival of *psychotherapeutics*, lest, as sometimes happens, unassuming merit be deprived of the honour due to it, and other claims arise to obscure those of the real founders of the system.

Perhaps the most unfounded claim is that of the magnetizers, who assert that they have kept the subject before the public by their experiments and entertainments. This contention is easily answered, for, in the first place, the method practised by Dr. Liébeault, and described in these pages, differs in nearly every respect from that employed by such persons; and secondly, their performances have never done anything else but degrade this branch of medical science, and turn the medical profession against it. Their method is unchanged since the beginning of the century, and they have hardly even added a new trick to their stock-in-trade.

So low had the estimate of the scientific value of induced sleep fallen, that in 1874 the French medical dictionaries threw doubts on its existence, except as a pathological curiosity, and the English encyclopædists followed much the same course.

Since the year 1875—when Dr. Charles Richet began to write on the subject of hypnotism—there has been

no lack of scientific investigators on the Continent. Among the most distinguished of these are Charcot in Paris, and Heidenhain* at Breslau, and they have demonstrated beyond the possibility of doubt the genuineness of the phenomena of induced somnambulism. But long ere this—in 1860—Dr. Liébeault had opened his public dispensary at Nancy, and had elaborated his system, which he caused to be known as *Treatment by Suggestion*.

In 1866 he published a book on the subject, in which he gave to the world a full description of the means used by him, and an account of cases successfully treated.† But little notice was taken of it at the time, and even in Nancy, where Dr. Liébeault lived a retired life, devoted to the poor among whom he practised, he was regarded as, at the best, an amiable but mistaken enthusiast. In 1882, Professor Bernheim, of the Faculty of Medicine at Nancy, began to investigate the system, quite as a sceptic, so he tells us, and, being soon convinced of its value, introduced it into his hospital *clinique*. In 1884 he brought out his classical work on suggestion.‡

Dr. Bernheim was well known in the medical world, and his book attracted general attention on the Continent. Physicians began to practise hypnotism in many of the larger cities, and flourishing *cliniques* sprang up in all directions. Among the first and most notable of these are those of Drs. Van Renterghem, of Amsterdam; Wetterstrand, of Stockholm; Von Schrenk-Notzing, of Munich; Moll, of Berlin; and Bérillon, of Paris.

This book does not profess to give a literary history of the movement, and a glance at the catalogue§ given by Dr. Max Dessoir of recent publications on hypnotism is

* 'Hypnotism; or, Animal Magnetism,' second edition, London, 1888.

† 'Du Sommeil et des Etats Analogues, considérés surtout au point de vue de l'action du Morale sur le Physique,' Paris, 1866; second edition, 1889.

‡ 'De la Suggestion, et de ses Applications à la Thérapeutique,' Paris (second edition), 1887.

§ 'Erster Nachtrag zur Bibliographie des Modernen Hypnotismus,' Berlin, 1890.

enough to deter any but the most determined student from approaching the subject. During the two years 1888, 1889, there appeared nearly 400 books, pamphlets, and articles on hypnotism. A large proportion of these are by medical men, and are written in the French language. But among the pioneer writers on hypnotism must be named Professors Beaunis* and Liégeois,† of Nancy, who have treated the matter from the standpoint of their special departments, physiology and jurisprudence. Professors Delbœuf, of Liège; Fontan and Ségard, of Toulon; Preyer and Max Dessoir, of Berlin; Krafft-Ebing, of Vienna; Forel, of Zurich; Wetterstrand, of Stockholm; Van Renterghem and Van Eeden, have given us thoroughly practical books describing their practice, and Dr. Albert Moll's book is as well known in England as in Germany. On the eve of his retirement from practice, Dr. Liébeault has issued a new volume containing the results of his thirty years' experience, and this book will be in the hands of every student of the Nancy treatment.

In 1889, I wrote that, as far as I knew, there was no literature in English on the subject, and Dr. A. T. Myers, commenting in the *Practitioner*‡ on the backwardness shown by the profession in this country in investigating hypnotism, cited the references to the treatment in the medical journals of the world during the year 1888. He found only seven notices in English journals, against sixty-one in those of France, thirty-five in Germany, twenty-two in Italy, and sixteen in those of the United States.

But during the last few years a great change has come over the scene, and there are allusions to hypnotism in almost every issue of our medical journals. Drs. Kingsbury, Bramwell, Woods, and others, have published cases, and the question is now well before the profession. Dr.

* 'Du Somnambulisme Provoqué,' Paris, 1886.

† 'De la Suggestion et du Somnambulisme dans leur Rapports avec la Jurisprudence et la Médecine Légale,' Paris, 1888.

‡ Vol. i., 1890, p. 201.

Felkin, of Edinburgh, has written a masterly exposition of hypnotism in the *Edinburgh Medical Journal* (vol. xxxv.), which is republished in book form ('Hypnotism, or Psycho-Therapeutics,' Edinburgh, 1891); and Dr. Hamilton Osgood, of Boston, has contributed to the *Boston Medical and Surgical Journal* (1890) an extremely interesting article illustrated by cases. Dr. Kingsbury has published a valuable practical handbook, and the English translations of the works of Bernheim, Moll, and Wetterstrand have had a very large circulation. An excellent exposition of the subject is published by Dr. Ralph Vincent as a volume of the International Scientific Series. There is therefore no longer any need to lament the want of literature on hypnotism in the English tongue.

The following list gives a few of the more important books and papers recently published on hypnotic suggestion:

Liébeault: 'Thérapeutique Suggestive, son Méchanisme,' etc., Paris, 1891.
Bernheim: 'Hypnotisme, Suggestion, Psycho-therapie,' Paris, 1891.
Fontan et Ségard: 'Eléments de Médecine Suggestive,' Paris, 1887.
Delbœuf: 'De l'Origine des Effets Curatifs de l'Hypnotisme,' Paris, 1887.
A. Pitres: 'Leçons Cliniques sur l'Hystérie et l'Hypnotisme,' Paris, 1891.
Bonjean: 'L'Hypnotisme, ses Rapports avec le Droit et la Thérapeutique.'
Van Renterghem et Van Eeden: 'Clinique de Psycho-thérapie Suggestive,' Brussels, 1889.
Von Krafft-Ebing: 'Eine experimentelle Studie auf dem Gebiet des Hypnotismus,' Stuttgart, 1889.
Von Schrenk-Notzing: 'Ein Beitrag zur therapeutischen Verwertung des Hypnotismus,' Leipsic, 1888.
Forel: 'Der Hypnotismus, seine Bedeutung und seine Handhabung,' Stuttgart, 1889.
Forel: 'Der Hypnotismus, seine psychophysiologische medicinische,' etc., Stuttgart, 1891.
Preyer: 'Der Hypnotismus,' Vienna and Leipsic, 1890.
Moll: 'Der Hypnotismus,' Berlin, 1890 (second edition).
Wetterstrand: 'Der Hypnotismus und Seine Anwendung in der Practischen Medicin,' Vienna and Leipsic, 1891; English translation, 1897.
Lehmann (of Copenhagen): 'Die Hypnose,' Leipsic, 1891 (German edition), 'und die damit vorwandten normalen Zuständten.'
Morselli: 'Il Magnetismo Animale, La Fascinazione, e gli Stati Hypnotici,' Turin, 1886 (second edition).

Tanzi: 'Sulla cura suggestiva del morfinismo,' Naples, 1889.
Herrero: 'El Hypnotismo y la Sugestion. Estudios de Fisio-psicologia y de Psico-terapia,' Valladolid, 1889.
Hamilton Osgood: 'Hypnotic Suggestion,' with notes of 34 cases, Boston, 1890.
Kingsbury: 'The Practice of Hypnotic Suggestion,' Bristol (second edition), 1893.
Vincent: 'The Elements of Hypnotism,' London, 1897.
Voisin: 'Suggestion Hypnotique dans certaines formes d'Alienation Mentale,' Paris, 1897.
Bérillon: 'L'Hypnotisme et l'Orthopédie Mentale,' Paris, 1898.
Felkin: 'Hypnotism or Psycho-therapeutics,' London, 1890.
Hack-Tuke: 'Sleep-Walking and Hypnotism,' London, 1884.
Hy. Barwise: 'Hypnotism: Its Possibilities, its Uses and Abuses,' Birmingham, 1888.
Gerald Yeo: 'The Nervous Mechanism of Hypnotism,' London, 1884.

Students of contemporary hypnotism will find the subject exhaustively dealt with in the *Revue de l'Hypnotisme*, a medical journal devoted to this branch of therapeutics, published monthly in Paris, under the able editorship of Dr. Edgar Bérillon,* and in the *Revue de Psychologie*, also a Paris journal.

In Germany there is the *Zeitschrift für Hypnotismus*, published every month in Berlin. There is no journal devoted to the subject in England, but hypnotic treatment is frequently referred to in the ordinary medical periodicals. Luminous articles have appeared in the *Journal of Mental Science* by Dr. Woods, of Hoxton House Asylum, 1897, and in *Brain* by Dr. Milne Bramwell, 1897-99. I have written a fairly exhaustive article in the *Medical Annual* for 1898.

In the *British Medical Journal* for August 20, 1898, there is a full report of an important discussion on hypnotism at the Edinburgh meeting of the association, and I think we may say that there is no longer any prejudice against hypnotism in the best medical circles.

A recent paper read before the New South Wales branch of the British Medical Association by the Hon. J. M. Creed, M.R.C.S., Member of the Legislative Council, published

* Dr. Bérillon has a good clinique at 49, Rue Saint-André-des-Arts, Paris, which is largely attended by French and foreign doctors. He extends a cordial welcome to English medical men who wish to learn something of the practical use of hypnotism.

in the *Australian Medical Gazette*, January 20, 1899, entitled 'My Experience of Hypnotic Suggestion as a Therapeutic Agent,' gives an interesting account of successful hypnotic practice in the Antipodes.

The Society for Psychical Research has done, and is doing, much good work in the scientific investigation of hypnotism, and its members were among the first persons in this country to recognise its importance as an aid to experimental psychology. The clear and able papers contributed by Mr. F. W. H. Myers, the late Edmund Gurney, and other writers, in the Proceedings of the society, are among the best things which have been written on the subject.

To James Braid, the Manchester surgeon, is due the credit of having seen the germs of truth which lay hidden and obscured in the writings of Mesmer and the animal magnetizers. He attempted to explain by physical laws the effects produced by mesmerizers,* and he ridiculed the notion of there being any such thing as a magnetic fluid or current. His disgust for the mysticism of mesmerism drove him, perhaps, too far towards the other extreme, and made him more rationalistic than the facts warranted him in being. Although he publicly demonstrated his system of healing—which he practised with much success—and wrote several works upon the subject, it appears to have died with him, and it remained for Dr. Liébeault to arrive at the truth of psycho-therapeutics.

The most important recent event connected with the progress of hypnotism in this country was the appointment of a commission by the British Medical Association as a result of the important discussion at the annual meeting held at Birmingham in 1890. The report of this committee will be found in the appendix. It is hoped that the result will be increased interest in the subject by medical men and the prohibition of its use by showmen

* 'Neurypnology,' London, 1843; 'The Power of the Mind over the Body,' London, 1846.

and idlers. No one wishes to restrict the use of hypnotism in the researches of men of science, for this most interesting study affords a key, as Professor Preyer says, to many psychical and physical processes connected with the nervous system; but we feel convinced that in the interest of the public, and for the dignity of the subject, it will be necessary to surround its employment with precautions against abuse.

One looks forward to a time, in a not very remote future, when Englishmen will take that leading position in the investigation and practice of hypnotism which one would expect from the compatriots of James Braid.

The present movement is practically the third revival of psycho-therapeutics in modern times. That inaugurated by Mesmer in 1776 came to nothing on account of the fraud, ignorance, and exaggeration with which it was surrounded, and the second under Braid found even less acceptance from contemporary men of science; but the revival we now see is probably destined to make a deep and permanent impression on the history of medicine. It is the outcome of evolution and scientific progress in all departments of medical knowledge, and the time is ripe for its recognition and reception.

I believe that all great discoveries are led up to by previous half-discoveries; and it does not detract from Dr. Liébeault's credit that he started with a large amount of evidence on the subject collected by earlier observers, any more than Darwin's claim to be the first evolutionist is weakened by his having drawn on the material supplied by Lyell, Hooker, and a multitude of others. Liébeault's genius taught him to arrange and systematize the facts collected by his predecessors, and to find the true explanation of phenomena which they had misunderstood. And his patience and steadfast courage led him to persevere in his work, undeterred by opposition or neglect, until now we find him the founder of a school which, as I have said, has its representatives all over the Continent—acute and clear-sighted men of science, of a class quite unlikely to

entertain the fanciful theories of mesmerism, on the one hand, or those of 'faith-healing' on the other.*

I need hardly say that medical hypnotism has nothing in common with spiritualism, and it is a curious thing that in this country some persons seem to think them associated.

* The truth of this assertion has been agreeably verified by events. Dr. Liébeault has retired from practice, and visitors to Nancy will no longer have the pleasure of seeing him at his *clinique* and listening to his kindly talk. He has worked all these years from love of his profession, and not from desire for gain, and he has retired on a modest competence not acquired from his practice, which was wholly unremunerative. To celebrate the occasion, many of those who had enjoyed his friendship and derived profit from his instruction decided to present him with a testimonial. The movement was joined in by medical men from all parts of the world, and the presentation was made in May, 1891. There were over sixty subscribers to this testimonial, and among the contributors one finds many names of eminence in the profession, as Dumontpallier, of Paris; Preyer, of Berlin; Krafft-Ebing, of Vienna; Morselli, of Genoa; Cruise, of Dublin.—Vide *Lancet*, June 27, 1891, and *Revue de l'Hypnotisme*, June, 1891.

CHAPTER II

Examples showing the Power of the Mind over the Body.—Anæsthesia produced by the Imagination without Chloroform.—Cures effected by the Imagination and by Mental Emotions.—Illness and Functional Disorders induced by Morbid Direction of Thought.—Organic Changes possible from the same Cause.—Illness, and perhaps Death, caused by Suggestion of Symptoms.—Auto-Suggestion.—Simulated Death.—Cures at Shrines and Holy Places.—Touching for the King's Evil.—Modern Instances of Efficacy of Royal Touch.

ALL who have given any attention to the subject acknowledge what immense power the mind—acting in conjunction with or apart from the will—has over the body, forcing it at times to unusual or even extraordinary effort. This power is exercised both in health and disease, but is peculiarly evident—perhaps because it is more closely observed—in the latter condition. Everyone, the physician and psychologist especially, knows some curious instances illustrative of its effects; such as the story of the hospital patient to whom the consulting physician gave a prescription, with the remark, 'Take this, it will do you good.' At the man's next visit, he, being asked for the prescription, replied that he had swallowed it as directed, and it had, according to promise, done him 'a power of good.' Dr. Hack Tuke* gives a number of cases in which drugs have acted not according to their proved properties, but according to the expectation of the patient. For instance, a student having asked for an aperient pill, the dispenser, by mistake, gave him one composed of opium and antimony, which, instead of producing the usual effect of inducing

* 'The Influence of the Mind upon the Body,' London, 1884.

perspiration and drowsiness, acted in the way the student expected. Every medical man can quote examples of this sort from his own practice, and if sometimes he is wrongfully accused of having produced baneful effects, he is indemnified at others by having marvellously good results ascribed to very simple measures.

There are few cases of this kind more remarkable than one related by Mr. Woodhouse Braine, the well-known chloroformist. Having to administer ether to an hysterical girl who was about to be operated on for the removal of two sebaceous tumours from the scalp, he found that the ether bottle was empty, and that the inhaling-bag was free from even the odour of any anæsthetic. While a fresh supply was being obtained, he thought to familiarize the patient with the process by putting the inhaling-bag over her mouth and nose, and telling her to breathe quietly and deeply. After a few inspirations she cried, 'Oh, I feel it; I am going off!' and a moment after her eyes turned up, and she became unconscious. As she was found to be perfectly insensible, and the ether had not yet come, Mr. Braine proposed that the surgeon should proceed with the operation. One tumour was removed without in the least disturbing her, and then, in order to test her condition, a bystander said that she was coming to. Upon this she began to show signs of waking, so the bag was once more applied, with the remark, 'She'll soon be off again,' when she immediately lost sensation, and the operation was successfully and painlessly completed. This girl had taken ether three years before, so that expectation and the use of the apparatus were sufficient to excite her recollection, and call back the effects of the drug as then experienced.

But this recalling of a past impression does not explain the experience of Dr. A., who is anæsthetist to a large dental hospital. He tells me that he often pretends to give gas without doing so, and he finds many patients become anæsthetic when he simply places the apparatus over their face, tells them to breathe deeply and go to

sleep. He finds anæmic girls are the best subjects for this harmless deception.

It is told that when Sir Humphry Davy was investigating the properties of laughing-gas—as nitrous oxide was then called—he proposed to administer it to a man who was suffering from tic-douloureux, but before doing so he tried his temperature by putting a thermometer into his mouth. The man took this instrument for some new and subtle remedy, and in a few minutes exclaimed that the pain was cured. The same belief in the efficacy of the thermometer remains to this day among the uneducated, as a friend of mine found to his cost when he was hospital-clerk to a well-known physician. It was his duty to take each morning the temperature of every patient; but on one occasion, being pressed for time, and knowing by experience that a certain patient's temperature was always normal, he saved a few minutes by leaving it untried. Later in the day, when the physician asked this man how he felt, he replied that he was much worse, as might be expected considering the way in which he was neglected. On inquiry it came out that the potent charm of having the glass tube in his mouth for three minutes had been omitted, and my friend got a reprimand.

While in Jamaica, I knew a young lady who had for months been confined to her bed or couch, unable to walk a step, from apparent paralysis of the lower extremities, which entirely defied the treatment used. One morning news was brought to her that her brother, to whom she was devotedly attached, had fallen from his horse, and was lying in a critical condition some miles away in the mountains. She immediately got up, herself helped to saddle a horse, rode to the scene of the accident, and nursed her brother night and day for a week. She was completely and permanently cured of the paralysis, which of course was merely functional and hysterical, by the nervous shock which had brought her will into operation.

A somewhat similar case came under my observation

some years ago. A clergyman in whose house I was staying had long been a sufferer from chronic rheumatism, through which he was so disabled that he could only walk very slowly and with great inconvenience. On this occasion he was lying on a sofa, from which he could see through an open door and across a hall into another room, where his wife happened to be. By some careless movement she upset a table there, and, as if by magic, he sprang to his feet and walked rapidly and with a perfectly even step into the opposite room, exclaiming, 'There goes all the ink that was in the house, and I have to write my sermon!' In this instance, however, the cure was as ephemeral as the emotion which had caused it; but it is not improbable that a continued excitement might have prolonged the power of easy motion, and so have broken down and caused absorption of the adhesions and exudations which produce the pain.

I remember at a water-picnic a young lady complained of terrible neuralgia. From some cause the boat began to rock violently, and she became extremely nervous. Her fear of being upset completely drove away the neuralgia, which did not return, at least on that occasion. It is known that sufferers from sea-sickness almost invariably become quite well in moments of danger; and we can often lose the sense of pain by occupying our mind with some affair of great interest.

Dr. Laycock ('Nervous Diseases of Women,' p. 184) quotes the case of a gentleman suffering from quotidian ague who became so interested in conversation on one occasion, that the hour for his paroxysm passed without his perceiving it, and he escaped the attack. This story gives one ground for believing a statement frequently made—that the time of the recurrence of attacks of intermittent fever may be altered by moving the clock-hands unknown to the patient, and thus arousing expectant attention.

On the other hand, Dr. Goodhart mentions the case of a hysterical woman who consulted a doctor about her

health. He examined her chest, and thought he detected signs of phthisis, and expressed great surprise that she had no cough. Though up to that time she was free from any symptom of the kind, the suggestion was sufficient to excite a most troublesome and obstinate cough which it was very difficult to cure. Dr. Goodhart cites this case as a warning to the practitioner against being too persistent in asking leading questions.* I have heard a nervous patient say that she now had the headache the doctor asked her about last week, but which was then absent.

Dr. Arthur, of Sydney, New South Wales, has ingeniously taken advantage of the fact that the force of suggestion is very greatly increased by hypnotism. He has reported in the *British Medical Journal* a series of cases in which he had tried hypnotism with excellent palliative results. But the pains returned from time to time, and it was impossible for the patients always to go to him for relief. He therefore hypnotized them, and told them that whenever their symptoms recurred they had only to take a dose of the medicine he would give them and they would experience immediate relief. Among these cases were one of carcinoma uteri, one of scirrhus of the breast, one of locomotor ataxy, etc., incurable diseases, in which all we can do is to relieve symptoms. The medicine he gave, which hypnotic suggestion caused to act as a panacea, was a mixture of tincture of valerian. He terms this method 'treatment by indirect suggestion.'

The power of religious ecstasy and absorbing religious contemplation, in all creeds and in all climes, to cause disregard of surroundings and contempt for physical suffering need not be insisted upon, for its reality is attested by all history. From the days when Queen Jezebel's priests mutilated themselves on Mount Carmel, to the present time, when we see the dervishes hurl themselves on the bayonets of our soldiers in the Soudan, utterly unmindful of the pains of death, and seeing only the plains of paradise beyond, the story is the same. A

* 'Common Neuroses,' Harveian Lectures, 1891.

condition similar to hypnosis undoubtedly prevails in such cases. It is asserted, and with some reason, that in many cases martyrs at the stake have been mercifully spared much of the suffering which seems inseparable from their cruel death, in consequence of a hypnotic state, with its attendant anæsthesia, being induced in them, partly the result of religious fervour and abstraction, and partly brought about by the glitter of the flames and the clamour of the crowd, overstimulating certain sensory centres to the consequent inhibition of others. The devotees of certain sects obviously undergo hypnotization before practising their rites, *e.g.*, the Aïssouans who recently visited London. These Arabs are hypnotized by their priest or chief, and in the hypnotic state allow themselves to be stung by scorpions and devour venomous snakes. The Indian ghost-dance, of which we have recently heard so much, is also a species of hypnotism. The warriors, under pressure of intense excitement, rapidly gyrate round a central point until they fall to the ground, sometimes in a state of lethargy, and sometimes cataleptic.

An eye-witness describes a Ceylon devil-dance in the *Nineteenth Century* for November, 1899. The priest-exorciser certainly hypnotized the patient, who was suffering from acute hysterical mania, and then used suggestion. The writer expresses the conviction that this treatment for the large class of cases supposed by the natives to be dependent on demoniac possession is of great antiquity in Ceylon.

Dr. Brown-Séquard relates a remarkable case of ecstatic catalepsy in a girl whom he was called in to see. She lived in Paris, close to the Church of St. Sulpice, and every Sunday morning at eight o'clock, when the bell began to ring, she used at once to rise from her bed, mount the edge of the bedstead, and stand there on tip-toe until the bell sounded at eight in the evening, when she returned to her bed. The board on which she stood was curved and polished, and it would have been impossible for the most athletic man to have remained on it in

such a position for more than a few minutes at a time. While standing there, she was utterly unconscious of her surroundings, and continued murmuring prayers to the Virgin all the time, her hands clasped, her eyes fixed, and head slightly bent. Some of the bystanders were sceptical, and Dr. Brown-Séquard, to put her to the test, applied a strong interrupted current to her face. She showed no sign of pain, but the muscles reacted energetically, and her intonation was therefore slightly affected. The girl was weak and anæmic, and was so thoroughly exhausted by her Sunday exertions, that the remainder of the week she could only lie helpless in her bed. The enormous increase in muscular and nervous force in one direction (dynamogenesis) was accompanied, as is invariably the case, by inhibition of other functions—in this case, those of higher cerebration.*

A rudimentary knowledge of electricity is sufficient to assure us that the vast majority of popular electrical appliances—such as belts and pads—are absolutely inert, and that the good they undoubtedly achieve in some cases is due to their stimulating effect on the imagination.† If the public confidence is shaken, cures no longer take place, as was clearly demonstrated in the recent notorious electropathic belt trial. I am acquainted with a civil engineer of good standing in his profession, who assured me he had been cured of lumbago of very long standing by one of these belts, and he actually gave the proprietors a testimonial to that effect, which was widely published. The exposure in court of the inertness of the appliance opened this patient's eyes, and he acknowledged that the cure was largely due to imagination and suggestion. Next time he gets lumbago he will seek a new specific which will appeal to his imagination in a different way, for he thinks himself much too clever for orthodox medical treatment. Cholera-belts, camphor-bags, and such-like 'pre-

* *Revue Hebdominaire*, 1882, p. 36.

† *Vide* letter by Dr. Steavenson in *Lancet* and *British Medical Journal*, October 16, 1889.

ventives,' probably act in a similar way. Therefore, though these and kindred contrivances do not operate in the expected manner, I should be sorry to say that they do not serve a useful purpose; by inspiring confidence and keeping alive hope, they often enable their possessor to go unharmed in the midst of contagion, or help him to overcome disease; for there is no more effectual depressant, no surer harbinger of disease, than fear. Much of the immunity from infection enjoyed by physicians and nurses is due partly to the preoccupation of their minds, which leaves no room for selfish terror, and partly to the confidence begotten by long familiarity with danger.

The plan of substituting a harmless draught for the narcotic mixture, without which a nervous patient thinks himself unable to sleep, is, as we all know, continually resorted to, and is an instance of the beneficial employment of the imagination.

Drs. Beard and Rockwell relate how they experimented on rather a large scale with patients in a New York hospital with inert drugs. On one occasion, to see what imagination would do, they suddenly had the patients in one ward informed that a mistake had been made by the dispenser, and that an emetic had been administered to some of the patients instead of the usual mixture. A large proportion of the patients were thereupon seized with vomiting, and brought up the harmless dose which had been given to them.* This effect of the imagination it is not difficult to understand, but Dr. J. W. White, Professor of Clinical Surgery in the University of Pennsylvania, has collected a large number of instances showing the beneficial effects of surgical operations *per se*. Hospital surgeons are not supposed to be particularly imaginative, and yet Dr. White tabulates hundreds of cases which he has brought together from recently published medical journals, English, American, and foreign.

For instance, he records fifty-six cases of trephining for epilepsy in which nothing abnormal was found to account

* 'Sexual Neurasthenia,' New York, 1890.

for the symptoms, and yet twenty-five of these cases were cured, and eighteen improved.*

In thirty epileptic cases a bloodvessel was ligatured, generally one of the vertebral arteries, and cure had resulted in fourteen cases, whilst fifteen were improved. In nine cases the operation was tracheotomy, and two of these were cured, and six greatly improved. Dr. White instances several cases in which exploratory incisions under chloroform have revealed no disease, but have been followed by the cure of symptoms simulating disease, and from his experience he feels justified in considering that 'there are large numbers of cases of different grades of severity and varying character which *seem* to be benefited by operation alone, some of them by almost any operation.'†

We know that appendicitis is a much more common disease now than was formerly supposed, and that many lives are saved by its early diagnosis and operative treatment, but many people think that the prevalence of the disease is rather overdone in America. A large proportion of my American friends have had the appendix removed. Dr. Hodgson tells me that a prominent New York surgeon, himself a pioneer in the operation for appendicitis, was recently taken ill with the symptoms of that disease. It was diagnosed as such by himself and the surgeons he called in, and he was operated on; but no lesion was found when the abdomen was opened, and the wound was stitched up, and the patient told of the result. He benefited, however, by the operation, and was soon well again and at his work.

The cure of warts by charms and spells is, I believe, a matter of common belief in every village in England. A

* The extraordinary number of perforated skulls found in neolithic monuments was puzzling to antiquarians until the theory was adopted that they were the results of trephining for epilepsy. The success of the operation must have encouraged the men of science of those days to hold to their belief that the demon of epilepsy was expelled through the hole thus made.

† *Annals of Surgery*, St. Louis, 1891.

medical friend practising in the country told me not long ago that he had twice excised a number of warts from a boy of thirteen, and each time a new crop had soon grown. An old village woman recited some apparently childish formula over them, and behold the warts withered away, and in a few days had fallen off and disappeared. My friend is extremely orthodox, and did not at all understand nor approve of such interference with his patient.

On the other hand, it is possible for an apparently quite healthy person to develop, by pure imagination, the symptoms of serious illness. Laymen who dabble in medical science, and medical students at the beginning of their course, are apt to imagine that they have one or other of the diseases they have been studying, heart-complaint being perhaps the most usual; and of this they do frequently develop some of the subjective symptoms.

A friend of mine tells me that once only in his life has he suffered from laryngitis and loss of voice. This was while attending Sir Felix Semon's lectures on diseases of the throat. It may have been a mere coincidence, but that hardly explains the frequent instances of medical men who have succumbed to the disease which they have made their special study, *e.g.*, Professor Trousseau from cancer of the stomach. It is possible that the mind, being continuously fixed on one special organ, predisposes to disease of that organ.

Hypochondriasis is, as we know, a condition in which the patient feels the working of his internal organs, and is morbidly conscious of them. It tends to grow worse, because his attention becomes more and more fixed upon functions which ought to be performed automatically, and unless some powerful mental stimulant is applied, organic disease is sometimes actually set up. The late Sir J. Russell Reynolds* has collected and classified several cases of paralysis dependent on functional causes, which were cured by careful treatment directed chiefly to the

* *British Medical Journal*, vol. ii., 483, 1869.

morale of the patients. He points out the difficulties attending the ordinary treatment, and shows how necessary it is to counteract the morbid ideas which are often at the root of the mischief. Most of the cases to which he refers were cured, but some resisted all forms of treatment. Dr. James Reynolds* relates a case of a woman who died in the Birmingham General Hospital from the effects of hysterical paraplegia; the necropsy showed that there was no organic disease. He thus summarizes the dangers of this condition: 'If the nature of the malady be mistaken, and the stimulus of the will be habitually withheld from the inactive muscles, the nutrition of that part of the nerve centre which presides over those muscles becomes impaired, and what was at the beginning a mere perversion of function is finally converted into real organic disease.' Russell Reynolds thus concludes his paper: 'I believe and know that many cases of apparently grave disorders of the nervous centres may be removed entirely; and that in other instances, when the ideal affection is grafted upon organic lesion, much may be done to remove the former, and afford so much of the stimulus of hope, that the cure of yet graver symptoms is brought within the range, not only of possibility, but of probability and of actual fact.' There are many people of both sexes who never hear of a disease without fancying they have it. The illness of a royal or distinguished sufferer, the progress of which is daily recorded in the newspapers, will sometimes become almost epidemic; thus, throat specialists can tell some curious stories of the increase of imaginary and real throat affections during the illness of the late Emperor Frederick. That fear will promote disease has been abundantly proved during outbreaks of cholera, small-pox, the plague, and other epidemics. Pseudo-hydrophobia is a recognised malady, and no doubt many supposed cures of hydrophobia have in fact been cures of this fear-induced imitation.

* 'Paralysis and other Diseases of Motion dependent on Idea,' *ibid.*, p. 632.

Dr. Laycock tells the story of a woman, aged forty-eight, who was in constant attendance on her daughter during her tedious labour. Though she had not menstruated—she had passed the menopause—for eight years, she experienced uterine pains, and had a sanguineous discharge from the parts, and the next day her breasts were swollen, painful, and discharging a serous fluid.* Quoting Sir Benjamin Brodie, he adds that patients have been so acted upon by their fears, and by seeing their friends affected, that they have imagined they have had tumours of the breast, and that it is not improbable that the disease has been so produced.

Nothing can illustrate this truth better than Kinglake's description of the behaviour of the Levantines during an outbreak of the plague at Cairo, showing how these terror-stricken people invited the very danger they feared: 'For awhile it may be that the caution of the poor Levantine may enable him to avoid contact (with the garments of passers-by), but sooner or later, perhaps, the dreaded chance arrives. . . . From that dread moment his peace is gone; his mind, forever hanging upon the fatal touch, invites the blow which he fears; he watches for the symptoms of plague so carefully that, sooner or later, they come in truth. The parched mouth is a sign—his mouth *is* parched; the throbbing brain—his brain *does* throb; the rapid pulse—he touches his own wrist (for he dares not ask counsel of any man lest he be deserted), he touches his wrist, and feels how his frighted blood goes galloping out of his heart. There is nothing but the fatal swelling to make his sad conviction complete; immediately he has an odd feel under the arm—no pain, but a little straining of the skin—he would to God that his fancy were strong enough to give him that sensation. This is worst of all. It now seems to him that he could be happy and contented with his parched mouth and his throbbing brain and his rapid pulse, if he only knew that there were no swelling under the left arm; but dares he try? In a moment of calmness and deliberation he dares not; but when for awhile he has writhed under the torture of suspense, a sudden strength of will drives him to seek and know his fate; he touches the gland, and finds the skin sane and sound, but under the cuticle there lies a small lump like a pistol-bullet, that moves as he pushes it. Oh! but is this for all certainty—is this the sentence of death? Feel the gland on the other arm. There is not the same lump exactly, yet something a little like it. Have not some people glands naturally enlarged? Would to heaven he were one! So he does for himself the work of the plague, and when the Angel of Death, thus courted, does in truth and indeed come, he has only to finish that which has been so well begun.'†

Liébeault quotes several authors to prove that many persons seem to have had the power of so dominating their bodies by the force of will that they succeeded in keeping off illness which threatened them,

* *Op. cit.*, p. 112. † 'Eothen,' p. 257.

and in some instances in averting or curing it when it actually had assailed them. Thus, he says, Pascal cured himself of neuralgia by steadfastly fixing his attention on other things, and Goethe relates how he got rid of a troublesome cough in the same way. They induced a condition which was practically identical with slight hypnosis, and suggested to themselves functional changes in the direction of health.

Liébeault tells me he is able to cure himself of slight maladies—such as facial neuralgia—by auto-hypnotism and auto-suggestion. He sends himself to sleep by fixing his gaze on some prominent object, such as a door-handle, and his mind on the disappearance of the malady, and he drops off into a doze, out of which he awakes cured! But I apprehend that such a result can only be achieved by a few, and that, as a rule, both the induction of hypnosis and the suggestions for cure must come from without. In most persons the disease dominates the system, and entirely prevents the presence of that state of mental receptivity and confidence which is an essential preliminary to curative auto-suggestion. *Vide* note, p. 348.

Professor Dubois (quoted by Laycock) divided hypochondriasis into three stages: in the first the mind only is affected; the patient is harassed by imaginary diseases, and concentrates his attention on one or other of the viscera, thereby changing their innervation and bringing about the second stage. In the third stage these nervous changes terminate in organic disease of the affected organ, and the evil ceases to be one of imagination alone.

We sometimes come across people who tell us they 'have no time to be ill'; and certainly reports of longevity show that rust destroys more than use, and that hale old age is more frequently attained by those who have led busy lives than by idlers. Idleness is a well-known factor in producing all kinds of ailments, real and imaginary, of mind and body, perhaps because the idle man, from sheer lack of interest in life, devotes too much attention to his own organism.

Imagination, combined with 'direction of consciousness' (Sir H. Holland) to a part, will produce results which have been noticed by many pathologists. John Hunter said he was confident of producing a sensation in any part of his body simply by concentrating his attention on it. Sir H. Holland observes*: 'In hypochondriasis, the patient, by fixing his attention on internal organs,

* 'Medical Notes and Reflections,' London, 1839.

creates not merely disordered sensations, but disordered action in them.' And again: 'When there is liability to irregular pulsation (of the heart), this is brought on and increased by a simple effort of attention.'

A medical friend of mine, who is affected with insufficiency of the mitral valves, tells me that he is hardly ever inconvenienced by it, except when he has to examine a patient with heart-disease. His attention is then drawn to his own weakened organ, and he suffers from palpitation.

The late Dr. Forbes Winslow, writing on this subject, says: 'It is a well-established fact that alterations of tissue have been the result of a morbid concentration of the attention to particular organic structures. Certain feelings of uneasiness, or even pain, originate in the mind a suspicion of disease existing in particular parts of the body, it may be in the lungs, stomach, heart, brain, liver, or kidneys. Some slight irregularities and functional disturbances in the action of these organs being noticed, are at once suggestive (to the hypochondriac) of serious and fatal disease being established in the part to which the attention is directed. This deviation from a normal state of certain functions frequently lapses into actual *structural* disease, as the effect of the faculty of attention being for a lengthened period concentrated on this action. The continuous direction of the mind to vital tissues *imagined* to be in an unhealthy state undoubtedly causes an exaltation of their special functions, and an increase of susceptibility, by (it may be presumed) concentrating to them an abnormal quantity of blood, this being followed successively by (1) undue vascular action, (2) capillary congestion, (3) an excess in the evolution of nerve force, and (4) appreciable *structural* alterations.'* Hysterical contraction of the lower limbs frequently leads to structural changes and disease of the spinal cord (Charcot, Gowers), from impairment of nutrition and trophic changes leading to softening. Dr.

* 'Obscure Diseases of the Brain and Mind,' London, 1860.

Hack Tuke says: 'If twenty persons fix their attention on their little finger for ten minutes, the result will be that most of them will feel decided sensations there, amounting in some to a mere sense of weight or throbbing, and in others to actual pain.' He endeavours to explain this by supposing that the act of attention excites an increased flow of blood to the part, and consequent increased vascularity of the sensory nerve-ganglia, so leading to subjective sensation; or that the sympathetic nerve-centres become excited, and the vasomotor nerves influenced thereby so as to cause in the finger temporary vascular changes which invoke sensation. He puts forward also a third hypothesis, which is interesting from the relation it bears to that given by Professor Delbœuf, of Liège (see p. 336)—that fixing the attention on a part of the body for some time renders us conscious of the working of functions which are usually performed automatically and unconsciously. Sir James Paget thinks that by nervous excitement the temperature may be raised to at least 101° (from the normal 98·5°); and Professor Wunderlich says on the same subject*: 'In hysterical neurosis elevations of the temperature even to excessive heights may occur without any motive at all.'† Sir S. Wilkes relates cases of extreme anæmia caused by depressing emotions; and this agrees with the experience of all medical men, as does also the opposite observation,

* 'Medical Thermometry,' New Sydenham Society, 1871.

† I was once called to attend a medical man, whom I found in a state of great alarm on account of the way his temperature was rising. He was an extremely nervous man, suffering from overwork and anxiety, brought to a crisis by a severe attack of bronchial catarrh. He took his own temperature every few minutes, and in less than four hours it mounted from 101°—which represented the amount of fever which one expected to be present—to 104°. He became almost delirious, and it took some time to soothe him; but in less than an hour the thermometer only registered 102°, and without any special treatment soon dropped to 100½°. In this case nervous excitement may be credited with having forced a rise of at least 2° F. Krafft-Ebing, in the celebrated case of Ilma S., was able by suggestion in the hypnotic state to bring about almost immediate depression of temperature to the extent of two or three degrees (*vide* p. 69), showing the relationship between psychical and somatic processes under certain conditions.

that pleasant emotions bring about a good state of the blood and secretions, and improve the health. Instances in which the hair has rapidly, even in a few days, suffered atrophic changes, leading to its becoming white and falling out from excessive depressing emotions, are common—and under similar circumstances the teeth will sometimes rapidly decay.

Dr. de Watteville says*: 'One of the most striking properties of the nervous system is that by which the activity of one portion may be arrested or prevented—"inhibited"—by the activity of another . . . when we attend closely to a sensory impression or to a train of thought, the excitability of every part of the brain, except that actually engaged in the act, is diminished by an inhibitory action of the working portion. Thus, when we say that anger or fear paralyzes, we allude in very accurate language to the inhibitory influence which powerful emotion exercises on the cerebral functions.' Sir T. Lauder Brunton, speaking of the effect of emotion on the organs, says: 'Whenever emotional excitement is prevented from discharging itself externally by motor channels it is very apt to vent itself upon the internal viscera, and the principal channel through which it does this seems to be the vagus.' He instances the description of emotion without outlet given by Tennyson, in his poem 'Home they brought her Warrior Dead,' and points out how the poet recognised the reciprocity between emotion and motor impulses when he described the relief which followed on the sufferer bursting into tears and embracing her child.†

Dr. Laycock and other writers of forty years ago seem to have been well acquainted with the theory of inhibition, though the word is of more modern coinage, for he notices how the overactivity of one sense leads to a corresponding suppression of another, and he says: 'When the attention is directed to the perception of changes

* 'Sleep and its Counterfeits,' *Fortnightly Review*, May, 1887.
† 'On Inhibition,' West Riding Reports, 1874.

from without, there is such a change excited in the central terminations of the sensitive nerves, that more vivid perceptions result; and if the attention be concentrated on one set of nerves the others are in a state analogous to paralysis.' He instances the case of Marini, the Italian poet, who allowed his leg to be badly burnt before he was aware of it, so engrossed was he in poetical reverie (*op. cit.*, p. 110). He goes on to say that an act of the will will sometimes excite such changes in the brain as to arrest an incipient paroxysm of angina pectoris or epilepsy.

Dr. Charles Mercier, in his recent work, 'Sanity and Insanity,' refers to the rapid pigmentary change both as regards the hair and the skin produced by excitement and emotion, and gives as an instance the case of a young Bengalee with perfectly black hair, who was arrested on a grave charge and publicly examined. The danger and horror of the situation so affected him that his hair actually changed colour before the eyes of the spectators, and in the space of half an hour was of a uniform gray tint. That emotion and fancy have power to modify the secretions is shown by the well-known fact that the mouth becomes dry and parched through fear or anger, while on the other hand it 'waters' at the idea of savoury food, the mental impression paralyzing or stimulating the secretory apparatus of the salivary glands. Violent emotion, again, will so modify the secretion of gastric juice as to cause indigestion in subjects at all predisposed to it. An attack of jaundice may be induced by anger—as the popular saying, 'Green with rage,' implies—from an accumulation of bile in the blood through nervous excitement causing 'inhibition' of the healthy function of the liver.

Disease, then, as we have seen, may, in hypochondriasis and kindred states, be induced by *auto-suggestion*, and there is no doubt that it may likewise be induced by suggestion from without. Let a man be told repeatedly by his friends that he is looking ill, that he does not seem

fit to go about, that he must take care of himself, or he will have this or that complaint—and unless he has a very cheerful and well-balanced mind, he is pretty sure, for a time at least, to deteriorate in health. There is a story of such suggestions being made, for a practical joke, at the expense of a stalwart farmer, who, having been assured by several persons that he seemed in a bad way, did really take to his bed and go through an unmistakable attack of illness. This, of course, was a cruel and unwarrantable jest; yet a somewhat similar effect is occasionally produced by well-meaning persons, who are in the habit of commiserating their acquaintance for not looking well. Dr. Laycock (*op. cit.*, p. 112) says that the effect of 'fearful attention' has sometimes proved fatal, and instances the case of a man whose death that night was foretold by a ventriloquist at a dinner-party. So great was the effect of the prophecy that it fulfilled itself, and the unfortunate man actually died at about the time indicated. Sir William Gowers, referring to the influence the imagination may have on functions which are ordinarily beyond the control of the will, says that vomiting may be produced by an emotion of disgust, and the needed emotion may be called up without sensorial agency, as is shown by the strange cases in which the husband has retched in sympathy with the vomiting of his wife in pregnancy, and has at last become so sensitive that sickness occurs as soon as he knows his wife is pregnant ('Diseases of the Nervous System,' vol. ii., p. 928).

In subsequent pages I shall detail some experiments to show how greatly the will acting through suggestion is able to modify the action of the heart in hypnosis, but such modifying influence is not necessarily confined to the hypnotic state. As a rule we are unable to exert any decided influence over the vegetative organs by simple ideation, but Professor Tarchanoff has recorded the case of a student who had the power of accelerating his heart's action by no less than 35 beats in a minute. Tarchanoff

has very fully investigated and described the case, and he supposes that the acceleration does not depend upon deficiency in the controlling power of the vagus, but rather on increased control over the accelerators, which the student was able to exercise through the accelerator centres in the cord being connected with a will centre higher up.*

Dr. Hack Tuke gives an instance of death itself being produced by suggestion. A Frenchman of rank was condemned to death for some crime, and his friends, willing to avoid the scandal of a public execution, allowed him to be made the subject of an experiment. He was told that he must be bled to death. His eyes were bandaged, and his arm having been lightly pricked, a stream of warm water was made to trickle down it and fall into a basin, while the assistants kept up a running commentary on his supposed condition. 'He is getting faint; the heart's action is becoming feebler; his pulse is almost gone,' and other remarks of the sort. In a short time the miserable man died with the actual symptoms of cardiac syncope from hæmorrhage, without having lost a drop of blood. (*Vide* note in Appendix, p. 331.)

There are some authenticated cases of apparent death being produced by auto-suggestion. We hear of this being accomplished by Indian fakirs and other religious enthusiasts in Eastern countries. Braid cites a remarkable and, he believes, thoroughly well-authenticated instance of a distinguished holy man, who, to convince the Maharajah Runjeet Singh† that he possessed this power over himself, apparently died, and was laid in a sealed coffin within a vault, the entrance to which was also

* Quoted by Professor Hamilton, 'Text-Book of Physiology,' p. 569 (London, s. 1). On the other hand, Dr. Brown-Séquard relates how a student in his class was able at will to bring about an arrest of the heart's action (*Rev. Hebdominaire*, 1882, p. 36).

† This case is related in medical detail by Dr. McGregor in his 'History of the Sikhs,' p. 227. He was an eye-witness of the disinterment. There are other cases of a similar character, apparently well authenticated. The late Sir Richard Burton wrote to me on the subject, stating that he had investigated cases of vivi-sepulture, and was convinced of their genuineness.

sealed and guarded by soldiers. After six weeks, the time appointed by himself, he was taken out of the tomb in the presence of the Rajah and of several credible witnesses, English as well as native, and found to display every appearance of death. Having been gradually revived by his own servant, the still ghastly-looking, corpse-like creature sat up and spoke, his first words being addressed to the doubting Rajah: 'Do you believe me now?'

The best warranted European case of the sort is that of Colonel Townshend, related as follows by Dr. Cheyne: 'He could die or expire when he pleased, and yet, by an effort or somehow, he could come to life again. . . . We all three felt his pulse first; it was distinct, though small and thready, and his heart had its usual beating. He composed himself upon his back, and lay in a still posture for some time. While I held his right hand, Dr. Baynard laid his hand upon his heart, and Mr. Skrine held a clean looking-glass to his mouth. I found his pulse sink gradually till at last I could not feel any, by the most exact and nice touch; Dr. Baynard could not feel the least motion in the heart, nor Mr. S. discern the least soil of breath on the bright mirror. Then each of us by turns examined his arm, heart, and breath, but could not, by the nicest scrutiny, discover the least symptom of life in him. We reasoned a long time about this odd appearance, and, finding he still continued in that condition, we began to conclude that he had indeed carried the experiment too far; and at last we were satisfied that he was already dead, and were just ready to leave him. This continued about half an hour. . . . As we were going away we perceived some motion about the body, and, upon examination, found his pulse and the motion of his heart gradually returning; he began to breathe heavily and speak softly. We were all astonished to the last degree at this unexpected change.'*

* The starting-point of the movements of the heart is the excitation produced by the pressure of the blood on the sensory or centripetal nerve-fibres of the endocardium. If the contact of the blood with the endocardium be prevented, the heart ceases its pulsation, the physio-

As sickness, and perhaps even death, may be produced by suggestion, so may be, and very often is, produced the cure of sickness. Towards this, however, auto-suggestion, though it might do much, does actually little or nothing, the natural reason being that the mind of a sick person, when left to itself, is prone rather to suggest morbid than health-inducing ideas, and so operates for mischief rather than in the direction of cure. Every physician knows how, by determined hopefulness and cheerfulness, a sufferer from functional, and even from curable organic disease, may facilitate the work of healing, and materially hasten his recovery.

In all ages wonderful cures, real amid a multitude of shams, have been wrought at holy places dedicated to various saints of various cults. Among the throngs of pilgrims to Mecca, to the sacred rivers and temples of India, to the shrines of Buddhist hagiology, there are some who, having made the outward journey wearily and painfully, do indeed turn homeward with the gift of health. A proportion of those who have limped or been carried to Lourdes and to a hundred other holy places of the Catholic Church, do leave behind them crutches that they no longer require. Some of the sufferers who worshipped the Holy Coat at Trèves did truly receive in restored health the reward of their faith. Some wearers of relics and amulets are really the better for possessing them. The cheered, uplifted, and convinced mind works, sometimes with startling rapidity, on the diseased body.

For this same reason, touching for the king's evil did no doubt effect many cures. The royal progresses were announced some time beforehand, and the sufferers along

---

logical cause of the reflex action having been removed. If the chest, and consequently the heart, be compressed by a series of forced expirations and by holding the breath, so as completely to empty the lungs, and bring the muscular walls of the heart into close contact, we may succeed in stopping its beating. The performance of this experiment is not recommended, as it might have a fatal issue. *Vide* an article on 'La Mort simulée,' by Dr. G. Tourdes, 'Dictionnaire encyclopédique des Sciences médicales,' Paris, 1875.

their route had often weeks in which to cherish the expectation of healing, in itself so beneficial; and in those days of faith, when a belief in the divine right of kings was universal and strong, the touch of the royal hand must, except in the most hopeless cases, have had a stimulating effect which may often have caused a healthful reaction. Even in our own times, a royal touch, accompanied by kindly words, has good effect. We read in the 'Life of Victor Emanuel,'* that in 1865, when the cholera was raging in Naples, and the panic-stricken inhabitants were migrating by thousands from the city, the king, wishing to give his people courage, went the round of the hospitals. 'He stood beside the sick-beds, and spoke encouragingly to the patients.' Before one of those already marked for death, the king stopped, and taking his damp, frozen hand, he pressed it, saying, 'Take courage, poor man, and try to recover soon.' The warm grasp of the hand, the strong cheerful words, the recognition of the king's face, had an agitating effect on the dying man. That evening the syndic visited the king, and said: 'Your majesty's coming is a joyful omen. I am happy to tell you that the doctors report a diminution of the disease in the course of the day, and your majesty has unawares worked a miracle. The man you saw this morning stretched for death is out of danger this evening. The doctors say the excitement of your presence caused the salutary crisis.' In Carpenter's 'Physiology'† numerous

* 'Life of Victor Emanuel,' by G. S. Godkin, vol. ii., p. 213.

† 'On the Influence of the Nervous System on the Organic Functions,' chap. v., ninth edition. Perhaps the most striking example of the power of the will and imagination to affect function, and even to initiate it, is afforded in a few rare but well-authenticated cases collected by Dr. Dunglison ('Human Physiology,' vol. ii., seventh edition), and quoted by Carpenter, in which strong desire to furnish milk, combined with continued irritation of the nipple by the infant's mouth, has brought about a secretion of milk in the mammary glands of childless and unmarried women, and even of men. The not uncommon occurrence of pseudo-pregnancy, with production of all the subjective and many of the objective symptoms of real pregnancy, under the stimulus of a strong desire for children, affords evidence of the power of auto-suggestion. The historical case of Queen Mary is a familiar example.

examples are given demonstrating the influence of the mind and imaginative faculties on the different bodily functions, and we have only to consider a moment to recall many personal experiences pointing in the same direction.

Sir T. Lauder Brunton gives several examples, showing how vigorous belief on the part of a friend may avert what appears like inevitable death. For instance, when Melancthon was lying very ill, and apparently dying, Luther was sent for to see his friend. On his arrival, he said: 'You must not die, Philip; we cannot spare you.' 'Oh, let me die quietly,' said poor Melancthon. 'No, Philip, you must not die,' was the reply, followed by an impassioned prayer that Melancthon should live. The effect was soon apparent; the tide turned, and the sick man got well.

We know how in impressionable persons the idea calls up the sensation. Thus, talking or thinking of ants or fleas may produce irritation of the skin and formication, recollection of a certain dish may re-awaken its savour, and expectation of hearing a bell ring may so act on the auditory centres as to produce a subjective tintinnabulation. The suggestion of a person's presence may call up his image, as in the well-known story told by Dr. Wigan. He was in Paris, and at a reception given shortly after the execution of Marshal Ney. All the world was talking about the deceased general and his tragic end, when the servant threw open the doors and ushered in a gentleman whom he announced as 'Marshal Ney!' A dead silence came over the company, and a shiver ran through them as they glanced towards the door, and so strong was the mental picture conjured up by the servant's blunder that many of those present seemed to see the familiar figure stalking into the room. These examples serve to show how suggestion in the waking state many produce tactile, auditory and visual images by direct action on the highest centres, and they give us some clue to the phenomena observable in the states of hypnotism characterized by

heightened suggestibility. In the motor sphere we find the same phenomenon. The thought or idea of dancing often causes the feet to move in rhythm, just as the idea of a combat may lead us to clench the fist.* The thought-readers' success depends on the fact that the idea upon which the subject's mind is intensely fixed is betrayed to the practised 'medium' by unconscious and involuntary muscular movements.

But it is unnecessary to multiply instances showing the influence of the mental states over bodily functions, as everyone must have numberless examples of it in his own person. Mental discouragement and depression have as their accompaniments disinclination for exertion and very frequently a sense of bodily fatigue. Who has not felt such a combination of symptoms after disappointment and worry, and does not know that the removal of the cause is followed by immediate removal of the effect? A letter saying that the friend we mourned as about to die has recovered, or that the investment we thought hopelessly bad has turned out a brilliant success, not only removes the mental symptoms, but also seems to put new energy into our actions. The sense of fatigue vanishes, the muscles become braced up, and there is an immediate demand for an outlet of energy which has been liberated by the removal of the inhibitory effects of despair. The counterpart is equally apparent, for we know and have experienced the effect on the depressed and wearied mind of a game of tennis or billiards, or any form of

* Hypnotism greatly increases the ideo-motor association, as is shown by Professor Pitres, of Bordeaux. He hypnotized a young woman named Celestine, and she at once passed into a condition of profound trance, in which she lay motionless and expressionless. He asked what she was thinking of, and she replied, 'Nothing,' and her face showed no sign of intelligence. She was then placed in a kneeling position, with her hands clasped, and immediately her face, previously so dull and apathetic, lighted up, and assumed an aspect of devotion resembling that seen in religious ecstasy, while her lips were seen to move. 'What are you doing?' asked Dr. Pitres. 'Saying my prayers,' answered the girl. When asked what she saw, she replied, 'The Virgin,' and proceeded to describe her dress and appearance. The attitude suggested the idea, and the thought produced the hallucination.—Pitres, *op. cit.*, p. 155.

effort which acts as a derivative by calling off nervous energy from overworked and enfeebled centres into other channels and fresh combinations. The philosopher is indifferent to privation and suffering because he is able to direct his thoughts into channels which are not affected by the ups and downs of ordinary life, and his philosophy is practically the outcome of the development of his power of inhibition.

Hypnotism in some cases enables us to do for our patients what the philosopher can do for himself. The case of Mrs. E——, quoted on p. 314, is an example of this.

I have recently seen a lady whose condition is in some ways a typical example of the connection between mental states and bodily functions. She is a woman of thirty-five, and is married and has children. She has no organic disease as far as can be ascertained, and spends more than half her time happily and naturally. But she is subject to attacks of melancholia, and these generally come on every three or four weeks, and last about a week. She goes to bed feeling well, but awakes utterly dejected and miserable after a disturbed sleep of two or three hours. Her whole appearance undergoes a change; she looks much older, her complexion becomes muddy and sallow, and her skin dry and harsh, her eyes dull and heavy, her attitude and gait stooping and slow. The timbre of her voice alters, and her speech becomes slow. At the same time the bowels become obstinately confined, and the water high-coloured, thick and scanty. She also suffers at these times from constant frontal headache and loss of memory. During the attacks she suffers from insomnia, and when she does sleep, she has disturbed dreams, and is restless and agitated. It is interesting to note that she is naturally of an unusually bright and energetic temperament, and systematically overworks and strains herself. She comes of a neurotic family, and was scrofulous as a child. The attacks are often preceded by a period of unusual excitement and mental activity. In this brief sketch of a not unusual condition one sees the close connection between mental states and bodily functions, and it is not easy to say whether mind or body is the primary seat of disturbance. I am disposed to think that the symptoms depend on exhaustion of nervous energy in the highest centres of the cortical area, and that this exhaustion affects not only memory and sleep, but also nutritive and secretory processes.

CHAPTER III

Power of Mind and Body increased by Concentration of Attention and Energy.—Suppression of one Faculty tends to increase the Development of others.—Concentration of Mind on one Idea in Somnambulism, and Performance of Tasks impossible when Awake.—Some Tragical Results of Natural Somnambulism.—Artificial or Hypnotic Somnambulism may be turned to Therapeutic Purposes.—Natural Sleep may pass into Hypnotic Sleep, and *vice versâ*.—The Faculties may be aroused and intensified in Hypnotic Somnambulism.

I HAVE endeavoured to show how much the imagination (in its widest sense) may have to do with the health of mind and body; and I shall now try to point out that the effects of 'directed consciousness' are greatly increased under certain conditions, when the mind is so withdrawn from the consideration of all extraneous ideas as to be absolutely concentrated upon one object.

We have seen how concentration of mind-faculty, whether self-induced or brought about by some shock to the system, or some powerful external influence, can modify functions, and both produce and cure disease —sometimes gradually, but often, in the case of shock or sudden and overpowering influence, with a rapidity which seems almost miraculous.

We all know, and frequently by our own experience, that mind-concentration, brought about by some strong motive, will enable us to perform mental or bodily actions of which we would generally be incapable. Through it a man will achieve feats of strength far beyond his apparent muscular power, or will go boldly through dangers from which he would shrink if he paused to consider

probable consequences. Or he will, in a limited time, execute a prodigious amount of intellectual work, possibly of such startling excellence that he himself, in after-moments of less intensity, will be amazed at his own performance. Of course, concentration, if sustained at such a pitch, would in time be the ruin of mind and body; but we know that it is a necessary factor in the accomplishment of all great things, and that there can be no success in life for those who cannot command it to a moderate degree. Of this, we see a striking instance in Coleridge, who, with all his wonderful genius, brought a surprisingly small quantity of work to completion, for want of this mind-directing power. The less we have of it, the more our mental action tends to become automatic. The mind of a person unused to exercise it drifts undirected and undisciplined from one idea to another; he can hardly follow a line of thought to its conclusion, and his talk, and probably his actions, will be as inconsequent as his wandering fancies.

As a rule, happily, the organic functions which carry on life are purely automatic; but, as we have seen, it is possible to concentrate the attention upon them, and so affect their operation, sometimes beneficially, but far more commonly with detriment to the health of mind and body. Those bodily movements over which we have full control are also generally performed automatically. Under ordinary circumstances, we give no conscious thought to our steps in walking, to the motion of our hands while at work; these are nearly as automatic as healthy breathing. So likewise, in a general way, is the operation of the senses. We see, hear, feel without any effort of our will, unless some special motive impels us to exercise it. We concentrate our minds upon sight when we strive to see a minute, or indistinct, or distant object; and upon hearing when we listen for a faint or eagerly-expected sound. If such concentration is continuously brought to bear upon any sense, it will in time convey automatically the more intense impression which has

been exceptional. Thus, in savages and in travellers and settlers in wild or dangerous regions, the senses of sight and hearing are far more keen than in those who live under civilization. The senses of touch and hearing become exquisitely fine in the blind. A blind man will sometimes hear sounds which are absolutely inaudible to ordinary ears, and recognise objects by touch as correctly as most people can by eyesight. Some blind persons seem, through concentration, to have developed a sense of space. On entering a room they can tell whether few or many persons are present; they can guess with wonderful accuracy the size and shape of an enclosed place, and have a curious power of avoiding any obstruction, such as an article of furniture, which may be in their way.* Dr. Laycock relates how blind persons are able to recognise their friends by touch alone, and cites several instances in which, from a subtle comparison of form, smell, texture, etc., they have been able to form correct ideas about colour. In the well-known case of Caspar Hausen, who was brought up in solitude and darkness, all the senses were of extraordinary acuteness, so that he could distinguish colours in the dark and hear sounds inaudible to other people. The more recent example of Laura Bridgman must be familiar to most readers. Though blind, deaf, and dumb from infancy, she possessed great intelligence, and kept up close relationship with the outside world through the development of the sense of touch. She was able to recognise her friends after months of absence by the touch of their hands. Professor Binet investigated the case of a hysterical girl who, when blindfolded, could discriminate and describe the relieved surface of an unknown coin when pressed against the skin. He reckoned that she possessed in this respect fifty times the normal amount of sensitiveness.

* Most people have probably noticed that closing the eyes will, for the moment, render the hearing and touch unusually acute. Any sense may be intensified by mind-concentration, as in the case of tea and wine tasters, and of professional buyers of raw silk, who develop an unerring capacity of judging its quality by touch.

Hyperæsthesia of the special senses is not of uncommon occurrence in hysterical subjects; and I have met a young lady whose nights were rendered miserable by the noise made by billiard-balls used on a table at least fifty yards away, and quite inaudible to ordinary persons. Smell is almost a lost sense with a large proportion of civilized mankind, but in many hysterical and neurotic subjects it is developed to an even painful extent, so that persons and things are readily distinguished by their odour. Such sensory hyperæsthesia is readily produced in the hypnotic state by suggestion, and explains many supposed instances of clairvoyance. Deaf people often develop the sense of sight to an extraordinary extent. By concentration of this faculty they are able, as we know, to follow a speaker by watching his expression and the motion of his lips. Their sense of touch also becomes more delicate; and occasionally they are able to enjoy music by feeling the vibration of air set in motion by its sound.

Concentration of mind upon intellectual or physical action is usually possible only in our waking and wakeful moments. Fatigue of brain renders us incapable of it; and in sleep, the natural consequence of such fatigue, we generally lose consciousness, and only exercise those functions which are performed automatically. In dreams consciousness is once more aroused, and we may even use some reasoning power, and be influenced from without through our senses. But in ordinary dreams there is no concentration of ideas upon an act to be performed or a goal to be reached. When a sleeper uses this effort of mind, he passes out of the region of dreams, and enters that of somnambulism.

The somnambulist never has that semi-consciousness of his state, and of the unreality of his fancies, which sometimes exists through a dream—when the sleeper *knows* that he is dreaming, and will even try to prolong his vision if it be delightful, and dispel it if painful. Such an exertion of will is impossible in somnambulism. In this state all fancies *must* appear realities. The imagina-

tion is, as I have said, concentrated upon one object, and so completely that actions are as effectually performed as if directed by strong will-power. But an onlooker can easily perceive, by the expression and posture of somnambulists, that the discerning and judging faculties are in abeyance.

In somnambulism actions of extraordinary difficulty, such as could not be performed by the sleeper during his waking hours—except, perhaps, through mind-concentration caused by some overpowering impulse or motive—are accomplished with perfect ease. Persons in this condition will walk on the extreme edge of a precipice, climb dangerous heights, get out of a house through an upper-story window. There are numerous instances of this on record, of which I will quote two or three. Dr. Paul Garnier* gives one of a patient, a dentist's assistant, of feeble bodily and mental health, who frequently fell into a state of somnambulism. On one of these occasions he escaped by a window from the ward of the Hôtel Dieu, in which he was undergoing treatment, and, though a peculiarly unathletic person, walked easily and fearlessly along the sloping parapet of the façade—a feat which a trained gymnast could hardly have accomplished. He awoke in the course of this dangerous performance, and had to be rescued by means of a ladder. With the return of consciousness reason awoke, and he understood the horror of his position. While blindly obeying his impulse he had acted automatically, and fear, which is a product of reflection and association of ideas,† had no existence for him.

A patient of my own, a young man twenty years of age, not an habitual somnambulist, but a sufferer from nightmare produced by chronic dyspepsia, on one occasion, while spending the night in a hotel, dreamed that he was

* 'Somnambulisme devant les Tribuneaux,' Paris, 1888.

† Infants, in whom of course neither is possible, will, if allowed, grasp at the flame of a candle, or a sharp instrument; and young children will fearlessly put themselves into positions of great danger.

confined in a dungeon from which he must escape. The dream no doubt passed into somnambulism, for under its influence he broke his iron bedstead—a feat of strength which, waking, he assuredly could not have accomplished —and tore up his bed-clothes. His amazement was great when he awoke in the morning amid the ruins of his own creation. He remembered his dream, but had no recollection whatever of the acts into which he had been led by it.

Dr. Bevan Lewis refers to a case of habitual somnambulism with which he is acquainted. The subject, a medical man, is frequently called up at night to visit patients. He gets up and dresses automatically, but is quite unconscious of his actions and of his destination until he is a considerable distance from his house ('Text-Book of Mental Diseases,' p. 150).

The hypnotic state, which stops short of loss of consciousness, has been aptly compared to that condition between sleeping and waking which is characterized by inertia of mind and body, and by the greater or less abeyance of spontaneity. There is another similarity between the dream state and hypnosis. There are many cases on record, and most medical men must have met with instances in practice, where the morbid condition either took its rise from, or was coincident with, a terrifying or painful dream. Hysterical paralysis not uncommonly commences in this way, and it is probable that certain neurotic troubles take their form from the influence of dream-suggestion. In incipient insanity the delusions which subsequently become permanent and rampant are often at first only experienced either in dreams or in the moments of incomplete wakefulness, and their occurrence is due either to morbid auto-suggestion or to the influence of morbid conditions on the mind in the sleeping state which in waking moments are either not noticed or are corrected by the intelligence. It seems possible for healthy suggestion to combat and conquer many of the conditions which are thus ushered in.

Some years ago I attended a case in point. The patient, a lady of thirty, had always been neurotic, and had suffered from indifferent health. She was, however, able to get through life fairly well until in September, 1890, she went to stay away from home. In the evening the assembled company set themselves to tell the most blood-curdling stories they could think of, with the result that Miss X—— retired to her room in a state of terror, and with unstrung nerves. She had to sleep alone, a thing she was unaccustomed to, and this added to her alarm. In the middle of the night the house was aroused by screams proceeding from her room, and when an entrance was made Miss X—— was found in an attack of violent hysteria. When she recovered from the fit she was only able to remember that she had had a terrifying dream embodying the stories she had heard. From that time her health completely gave way ; she started at the least sound, ingestion of food was always followed by vomiting, and obstinate insomnia supervened. She underwent a six weeks' course of Weir-Mitchell treatment, from which she derived no benefit, and then, after a further three months of misery, expressed her wish to try hypnotism. She was not an easy subject, as her mind was in such a condition that it was almost impossible to fix her attention, and at first, whenever she felt going off, she could not help pulling herself up with a start. However, perseverance prevailed, and from the moment she was slightly influenced she began to improve. She was restored, after two months' treatment, to about the same state of health she was in before the attack.

Dreams merging into somnambulism may produce tragic results. Dr. G. Tourdes* relates how a man sleeping beside his wife dreamed that she was a robber whom he must kill. He accordingly attempted to suffocate her with a pillow, and it was with great difficulty that she succeeded in waking him, and so saving her life.

In 1843 a young man was tried for the attempted murder of an innkeeper at Lyons.† He had arrived at the inn towards nightfall, and was allotted a room. In the dead of night loud cries were heard from this room, and the landlord, rushing in to see what was the matter, was set upon by his guest and seriously wounded. It was ascertained that the young man was a somnambulist, who had dreamt that the landlord was murdering the occupants of a room near his own, and that he was defending them. He was, of course, acquitted. A case is also recorded by Drs. Guy and Ferrier, in their 'Forensic

* Article 'Sommeil,' 'Dictionnaire Encyclopédique des Sciences Médicales.'

† 'Dictionnaire Encyclopédique des Sciences Médicales,' article 'Somnambulisme,' by Drs. Ball and Chambard.

Medicine.' 'Two men, being in a place infested by robbers, engaged that one should watch while the other slept. But the watcher, falling asleep, and dreaming that he was pursued, shot his companion through the heart.'

We have many instances of mental work being accomplished during somnambulism. Professor Woehner,* of Gottingen, after vainly trying for several days to write a Greek poem on a given subject, composed it successfully while in this condition, which probably was brought about by the mental strain of his previous futile efforts.†

A clear case of somnambulism was that of a clergyman, whom his wife saw rise from bed in his sleep, go to a writing-table, and write rapidly for some minutes. This done, he returned to bed, and slept on until morning. On awaking, he told her that in a dream he had worked out an argument for a sermon, of which he now retained no recollection whatever. She led him to the writing-table, and showed him the written sheet, upon which he found his argument worked out in the most satisfactory manner.

It rarely happens, however, that solutions of problems, poems, etc., written by persons in this state, have any value. They may begin well, but generally drift into nonsense, probably because the mental concentration has been dispelled by some new idea crossing the first, and displacing it.

Habitual somnambulism may be natural—that is, may exist without any actual disease, though it is hardly ever found in persons of robust bodily and mental constitution. It is not uncommon in delicate or nervous children and young persons, but if with advancing years the mind and body gain strength, the tendency to it is likely to decrease

* 'Dictionnaire Encyclopédique,' etc.

† Coleridge's poetical fragment, 'Kubla Khan,' was probably composed in a dream—not in somnambulism—as he remembered and wrote it down on awaking.

and finally disappear.* *Accidental* somnambulism is directly produced by illness or mental strain, and may occur in normally healthy persons of great intellectual power. When the state is habitual or frequent, the somnambulist may be said to lead two lives, one almost distinct from the other, and to have two entirely unconnected memories. Memory, as we generally understand it, is dormant during somnambulism. The sleeper remembers nothing that has occurred during his waking hours, and, when he again awakes, has no recollection of his actions during the somnambulistic state. Yet, in his next attack of somnambulism, the memory of these is likely to come back to him.

The effect of natural or accidental somnambulism on the health is anything but beneficial. An attack is generally followed by feelings of weariness and discomfort, for which the subject is at a loss to account. The concentrated mind-power does not operate in a beneficial direction, but impels the sleeper to bodily or mental effort likely to have an exhausting and hurtful effect upon him. But the artificially-produced mental condition seen in hypnotism can be turned to therapeutic uses, and be made to fill a void which no other plan of treatment can reach. Dr. Bernheim considers hypnotic sleep analogous to the natural state, with the important difference that in natural sleep the subject is only in relation with himself, whereas in the artificial state he is in relation with the operator, who is therefore able to direct the thoughts into the channel he wishes. That it resembles natural sleep is proved by the fact that it is possible in certain cases for one to pass into the other. Dr. Van Eeden told me that a patient of his, a gentleman, wearied by long waiting and exhausted by the heat, fell asleep in the waiting-room. The doctor came in, and, seeing him asleep, said, 'Don't wake, but come with me into my consulting-room.'

* Ordinary somnambulism is best treated by hypnotic suggestion. I have cured several cases very speedily, and natural somnambulists are generally good hypnotic subjects.

The patient got up and, with assistance, did as he was desired. After the treatment was over he was led back in the same way to his former seat in the waiting-room, and allowed to finish his sleep. He soon awoke, apologized to the other patients for having slept, and expressed surprise that his turn had not yet come for seeing the doctor. Great was his astonishment when he was told that the séance had taken place and was finished without his knowing anything about it. Dr. Maury,* who cannot be accused of being too easily influenced, gives some instances in which, while sitting by his fireside dozing after dinner, he had heard, as in a dream, the words uttered by his wife and friends, and had followed out the train of thought suggested by them in his dreams, and had even acted upon suggestions so made.† If a person is very tired it is frequently possible to obtain an answer to a question whispered in his ear without awakening him. Dr. Hack Tuke and Mr. Braid give several examples of this in their writings.

Braid, for instance, tells of a naval officer who was the subject of many practical jokes. He entertained and, without awaking, acted upon any idea which was suggested to him when asleep. On one occasion, while lying in his berth, he was told that his ship was in action, and that his men were fighting all around him. His face immediately assumed an expression of martial excitement, and he wielded an imaginary sword. His friends supplied details of the fight, telling him that the battle was going against them, and that his dearest companions were being killed; then his expression changed to one of fear. Finally, when told that all his friends were slain, and that the rout was complete, he leaped from his place

* 'Le Sommeil et les Rêves,' Paris, 1865, p. 42.

† He relates how, on one occasion, he was sitting in his easy-chair half awake, when his wife spoke to him. He was awakened by the words, and remembered them, but was quite unable to tell whether he had uttered them himself, or whether they were his wife's. On this he remarks, 'How many actions and ideas are daily suggested to us by others which we act upon, thinking they are our own!'

and fled with an aspect of terror. I have myself spoken to and received answers from nurses who had fallen asleep, worn out by long hours of watching; and examples of such automatic answering must be familiar to most people. On the other hand, patients in the hypnotic sleep sometimes pass into the natural state, when they are no longer in relation with the operator, but follow their own ideas in ordinary dreams.

The close analogy between sleep and hypnotism is shown in many ways. If a person is hypnotized every night, hypnosis may be made to take the place of sleep for an indefinite time, and the only difference observable in the two conditions would be that in hypnotic sleep the patient would not be easily aroused, if at all, and would be *en rapport* with the operator. The experience of one of my patients also points to this close resemblance. When not able to sleep at night he now repeats on himself the process I used to adopt with him, viz., gentle stroking of the forehead. He tells me this never fails to send him to sleep in a few minutes. It would be interesting to ascertain if the sleep so induced possessed the characteristics of the hypnotic state. It is frequently possible to suggest dreams to the somnambulist. Thus I told an officer to dream that he was in Jamaica, and playing polo at Up Park Camp. When he awoke he volunteered the remark that he had had a most vivid dream, and proceeded to describe a polo match, of which he had filled in the details without help from me.

As in natural somnambulism a person may be able to do things of which he is at other times incapable, so in the artificially-produced condition he can sometimes be made to excel himself. Dr. Beaunis found in experimenting with the dynamometer that the muscular power could be greatly increased at times by suggesting in the hypnotic state increased strength and effort; and one frequently finds that the grasp of an enfeebled patient can be perceptibly strengthened by similar suggestions. The therapeutic bearing of this experiment is easily seen.

Dr. Grazzini, of Florence, has kindly sent me some copies of drawings done, while in a state of hypnotic somnambulism, by an uneducated man who in waking moments hardly knew the use of a pencil. These copies are faithfully and well executed, but probably the man would have been quite unable to initiate a design. The faculty of imitation was strengthened by the hypnotic condition, and at the same time he concentrated all his attention on the figures, and took infinite pains to reproduce them. I have frequently told somnambulic subjects that on awaking they are to write such and such a sentence with their left hand, and have invariably found the task accomplished fairly well, though in many instances I have heard the same person before the operation declare it impossible, and found him unable to make an intelligible letter. This may prove a practical hint in the case of left-handed children.

An artist under the same circumstances would no doubt produce a drawing in his usual style; and a musician, in a similar way, if asked to play, would perform some familiar air. Whatever a man's natural disposition might be, it would come out if he were in a state of profound hypnotic sleep; but we shall see that 'suggestion' in this condition has power to modify even life-long habits and deep-rooted tendencies.*

* Frequent repetition of the suggestion, especially if done with confidence, has what may be called a cumulative action, expressed by Professor Delbœuf in a kind of mathematical formula. This, of course, is also the case in our waking moments, and is well understood and turned to account by advertising tradesmen. The announcement in confident language on every blank wall, that 'Johnson's soap is the best,' becomes, by constant repetition, almost an axiom, and we are inclined to accept its truth. In the same way it is told of George IV. that from constantly repeating the story of his being at Waterloo, he at length got to believe that he had really taken part in the battle.

CHAPTER IV

Dr. Liébeault of Nancy.—Description of his Treatment.—System free from Mysticism.—Curative Suggestions.—Explanation of the Phenomena.—Definition of Hypnotism.—Absolute Sleep or Unconsciousness unnecessary for Curative Treatment.—Theory of Professor Charcot not accepted by the School of Nancy.—Proportion of Persons Hypnotizable and Degrees of Hypnotic Influence.—Phenomena of Somnambulism outside the Sphere of Psycho-Therapeutics.

I HOPE to have shown in the preceding chapters that Dr. Liébeault's system is the outcome of the collection and classification of many isolated facts previously neglected or misunderstood. That cures have been and still are worked by such means as are implied in faith-healing, the mind-cure, etc., and by charms and relics, is beyond doubt; but it is not in the supernatural that we should seek for the explanation of them. They all proceed from the same cause, and on the same lines. We have, first, the patient's strong desire for cure; and, secondly, his firm belief in the efficacy of the means used; while to these may generally be added the presence of a sympathetic and impressive environment. The reasonable and deliberative side of the patient's brain is suppressed, while the emotional or instinctive side is developed, and in proportion as the latter is predominant the greater generally is the success of the treatment. The Nancy school obtain, in suitable cases, as good results as it is possible to expect; but they work on scientific principles and by recognised laws.

A brief account of the treatment practised at Nancy,

and of the theory which explains it, will, I think, make this clear.*

If the visitor to Dr. Liébeault's dispensary be one who measures results by the impressiveness of the means used, he will surely be disappointed to find how commonplace are operators, patients, and building. The rooms are unpretentious, and even shabby; the patients are ordinary-looking people enough, belonging mostly to the artisan and labouring classes; and the doctor himself, though he has goodness and kindliness written on every feature, is of unimposing presence; while his habit of chatting on all sorts of subjects with the persons around him, even while receiving patients, has an odd and hardly impressive effect.

The patient paying his first visit is directed to sit down and watch the treatment being applied to others. This gives him confidence, and arouses that imitative faculty, which is so active in childhood, and is never lost throughout adult life. When his turn comes, he is told to take his place in an armchair, and to make his mind as much a blank as possible—'to think of nothing at all'—and to fix his eyes and attention on some special object; almost anything will do, from the operator's face or hand to a mark on the ceiling or the pattern of the carpet. Then the phenomena which attend the on-coming of natural sleep are gradually 'suggested' to him: 'Your sight is growing dim and indistinct; your eyelids are becoming heavy; a numbness is creeping over your limbs; my voice seems muffled to you; you are getting more sleepy; you cannot keep your eyes open.' Here the eyes close of themselves, or are closed by the operator, and it is generally found that the patient is indeed asleep.

About two minutes of this 'talk about sleep' will usually produce the hypnotic effect on a new patient; and on subsequent visits even less time is required.

* Dr. Rolleston gives an interesting account of a visit to Nancy in St. Bartholomew's Hospital Reports, 1889, and Sir Francis Cruise describes his visit in the *Dublin Journal of Medical Science*, May, 1891. See also the account of a visit to Liébeault's clinique by Sir T. Lauder Brunton in his book, 'The Action of Medicines,' p. 227.

The patient being more or less influenced, Dr. Liébeault now proceeds with the treatment proper. This consists essentially in directing the invalid's attention to the part affected, and suggesting an amelioration or disappearance of the morbid condition and symptoms. To take a very simple case—let us suppose that the malady is chronic nervous headache. The part of the head affected is gently rubbed, so that the patient's attention shall be attracted to it, and he is told that the pain is to disappear—that he will awake feeling his head cool, clear, and comfortable, and that there is to be no return of the trouble. In ordinary cases the whole process will not have lasted more than five minutes when Dr. Liébeault brings it to a close by arousing the patient, which he does by telling him to open his eyes and awake. This is generally enough; he awakes as from ordinary sleep, and is told to vacate the armchair in favour of the next patient. When asked how he feels, he will generally reply that he is better, and very often that the pain has entirely vanished. He is quite his natural self, and can leave the room at once and go about his work as usual. Long acquaintance with the system prevents an inhabitant of Nancy from regarding it as anything remarkable, and a sick person consults Dr. Liébeault just as he would consult any other physician, with the simple idea that the treatment will do him good. He does not trouble himself with metaphysical theories, but is content to know that some acquaintance has been cured of a complaint similar to his own, and that he himself hopes to be relieved in a few days. Liébeault generally places his hand over the epigastrium, and applies gentle friction, suggesting as he does so a sensation of warmth. He regards a responsive glow as almost essential to the success of subsequent treatment, and it is the first link in the chain which constitutes *rapport* between physician and patient. The fulfilment of the first suggestion tends to augment the patient's confidence, and leads to the more ready reception of those which follow. This point is one of great practical im-

portance, and we generally feel that we can do good when we can induce this responsive warmth, no matter how slight the hypnotic influence may be. The feeling is quite different to that produced by simple friction, and requires to be felt to be appreciated. The magnetisers attributed it to the passage of magnetic fluid from them to the patient; but, as we regard all the manifestations of hypnotism as subjective, we must of course seek another explanation. This is found by supposing that the sensation is due to action on the vaso-motor system through the solar plexus, allowing a sudden afflux of blood to the part. The warmth is not merely imaginary, for it is appreciable to the touch and by the thermometer, and is in fact analogous to blushing.

If the hypnotic sleep has been profound, it may be necessary twice or thrice to repeat the order to awake, and even to enforce it by fanning the patient, or blowing gently upon his eyes; but the simple command is nearly always sufficient.

There certainly is nothing mysterious in all this, and Dr. Liébeault seems to take pleasure in making his whole mode of treatment clear to any serious inquirer, and in giving the rational explanation of everything that he does. He directs the patient to fix his attention on a certain point in order to strain the accommodation of the eyes and tire the sight. The effect of the strain is to cause dilatation of the pupils and consequent dimness of vision. The feeling of heaviness in the eyelids results from the fatigue of keeping them open in a strained position, and the assertion that the eyes are becoming tired and the sight dim is therefore founded on physiological data, and is not guesswork. The eyes being tired, the natural impulse is to close them, and this act calls up a previous association of ideas connected with fatigued or confused sight. That association points to sleep, towards which the patient is rapidly led, aided by the monotonous tones of the operator suggesting it to him, and by his mind being free from all disturbing thoughts, and his nerves

from all external stimuli. He falls asleep, in fact, much in the same manner as one does when reading a dull book or listening to a not too brilliant discourse. Dr. Maury, in his well-known book on sleep and dreams, says: 'The less the mind is occupied with ideas, the more easily can the thoughts be directed into any given channel. If nothing claims our notice or holds our attention, the cerebro-spinal system, for want of that gentle stimulation which is necessary to it, falls into a state of semi-torpor inseparable from atony of the nervous system.'

In the chapter on sleep in Carpenter's 'Physiology,' various conditions are mentioned as being favourable to it, one being the desire for it, another the expectation of it. We expect, from previous experience, that if we lie down in a certain place, sleep will follow. The faculty of imitation helps to bring it about; when we see others dozing we naturally incline to follow their example, and at night the consciousness that all around us are asleep disposes us to seek the same condition. Talking about sleep is apt to induce somnolence, just as talking about food may provoke hunger. And a monotonous sound, such as a droning voice of a speaker, or the breaking of gentle waves upon the seashore, tends to encourage slumber. Thus it will be seen how closely the artificial method I have described follows natural rules. This method may fail, just as we may fail to obtain natural sleep, or may battle it off should we desire to remain awake. If a patient wishes to resist the somnolent influence, he can do so by refusing to concentrate his thoughts, or by inducing some physical discomfort—for instance, by placing himself in an uneasy position. Strong emotion, such as anger or fear, will prevent the hypnotic sleep; so will severe pain, hunger, thirst, and, indeed, anything which preoccupies the mind or agitates the nervous system. Constitutional idiosyncrasies affect this just as they affect the normal sleep. The naturally restless sleeper will be restless, and he who commonly goes off as soon as his head touches the pillow will quickly

succumb to the hypnotic influence. The extent to which a person is influenced varies according to his mental and physical condition. If he is of restless and flighty temperament, it may be impossible to fix his attention for even the few minutes that are necessary, and no effect is produced—except, perhaps, an inclination on his part to treat the whole affair as a jest, and a consequent irritation on the part of the doctor. But in ordinary cases some effect is certainly produced, if not on a first visit, still on subsequent ones. This effect will vary in various patients, some feeling only a heaviness and torpor, with a disinclination to open the eyes, while others fall into a more or less profound sleep, or into a state of somnambulism. Dr. Liébeault divides the sleep into six different stages,* but as these really merge imperceptibly into each other, the division is purely arbitrary, and is made for convenience in classification. They may be shortly summed up as: (1) Light sleep; (2) profound sleep; (3) somnambulism.

The first and second stages closely resemble and are analogous to ordinary sleep; but the third is *sui generis*, and will require a few words later on. Though it is analogous to natural sleep, there is one very important fact which shows that the conditions are not identical. If an ordinary sleeper is spoken to, he is generally aroused by the stimulating effect of the sound conveyed to the brain through the auditory nerves, but one in the hypnotic state may be talked to without being disturbed; the effect will, on the contrary, be soothing. He is, in fact, *en rapport* with the outer world, though only to a limited extent, whereas in natural sleep he is *en rapport* only with his own consciousness.

Upon this difference depends the possibility of applying curative suggestion. Carpenter (*op. cit.*) says that the very closure of the eyes renders the other senses more acute; and we have seen that the inactivity of one sense is nearly always compensated for by increased sensitive-

* See Appendix, p. 341, note 8.

ness of the others. Now, in the hypnotic state all the senses are more or less torpid and in abeyance until called into play by the operator. Physiologists suppose that during activity the nerve-centres are continually discharging nervous energy in all directions, in response to stimulating impressions received through the senses; but in sleep a state of inactivity is induced, and the nervous force accumulates in the brain cells. Natural sleep comes as a consequence of fatigue, and because the store of nerve-energy is nearly or entirely exhausted. During its continuance a fresh store of nerve-energy will be laid up, and if it be undisturbed, the store will go on increasing until sufficient is acquired for complete nerve recuperation. This point attained, the sleeper, if in good mental and bodily health, will awake naturally, and feel no further desire for slumber. But as the hypnotic state may be produced at any time in the twenty-four hours, and long before any perceptible inroad has been made on the store of nerve-energy laid up during the previous natural sleep, it follows that during the artificial sleep there may be great accumulation and excess of energy. All this can be concentrated and directed into any channel the physician may desire; and this concentrated and directed nerve-force must naturally affect the system more powerfully than any ordinary nervous impression. This fact may explain the rapid production of congestion to a given part (alluded to in Chapter V.), and also the sensation of warmth usually experienced in any part to which the attention has been drawn. It also accounts for the success of the treatment in some cases of paralysis of long standing.

We may imagine in such a case, and the surmise would probably be physiologically correct, that the nervous channels are blocked to ordinary impulses sent to them from the brain, but that the extraordinary impulse from an accumulation and concentration of nerve-force is sufficient to break down and overcome the obstruction; as a dam which easily withstands ordinary currents is swept

away upon the bursting of a reservoir, by the rush of accumulated water.

Bernheim defines hypnotism as *the production of a psychical condition in which the faculty of receiving impressions by suggestion is greatly increased.* But this is only half the truth; for not only is the receptivity increased, but the power to act upon and carry out the suggestion is increased likewise. Suggestions have all the force of commands, and the patient will strain every nerve to obey them. They are received as true, and the idea tends to be realized and to be carried into execution as action. If he is told to move a paralyzed limb, or to speak after months of loss of voice, one can see what intense effort he puts into the attempt to comply. A stammerer making such effort will speak fluently, and a deaf person will distinctly hear a whisper. To express adequately the cause of such effects, the word 'suggestion,' in English at least, is far too weak, and therefore somewhat misleading.

The increased force of suggestion does not depend so much as one might suppose on the profoundness of the sleep. In the case of deafness, referred to above, the hypnotic effect was extremely slight; and, on the other hand, I have heard a person in a state of decided somnambulism argue with the operator as to the correctness of his assertions. In applying suggestion, all that is necessary is a state of increased receptivity of ideas suggested by the operator, and an ignoring of other impressions. This attained, it matters little from a therapeutic point of view whether light sleep, profound sleep, or somnambulism, is produced. My own experience, like that of all observers whom I have known, is that good results are effected when there has been no loss of consciousness, and even when the patient denies having felt any hypnotic influence.* Dr. Arthur, when at the East End Wesleyan

* A gentleman, whom I have treated for various nervous affections, always denies having slept, and protests that he has remained conscious of everything going on around him. Yet if I put some small article, such as a paper-knife, into his hand during the sleep, and tell him to hold it tightly, he will do so, and on being aroused will show surprise at finding himself grasping it.

Mission, showed me a case of obstinate intercostal neuralgia after shingles cured in a single sitting, though the patient, a seafaring man of over forty, barely felt a slight degree of somnolence. He could have opened his eyes at any moment, but—and this is the important point—he was very conscious of a glow of reflex warmth when Dr. Arthur passed his hand over the seat of pain and suggested it.

Consciousness is lost only in the advanced stages of profound sleep, and even when this has occurred there is often partial remembrance on waking of many things that have happened during the sleep. A patient in profound sleep may be questioned, and will probably return answers, unless the question be put too brusquely, when it will be likely to wake him, or too gently, when he may shrink from replying; for a person in this state dislikes being disturbed, and is especially unwilling to exert his reflective faculties. Nevertheless, if questioned as to his complaint, he will describe his symptoms truthfully, and thus may help the physician in his diagnosis and treatment.

Bernheim seems to accept the theory of Herbert Spencer, and of most psychologists, that two sorts of nervous action go on within the brain—the one automatic and instinctive, the other rational, volitional, and deliberative. Hypnotism suppresses the latter (the *Ego* of some psychologists), and allows full play to the former. It follows that where the second kind of nervous action prevails in an individual, he is less liable to be acted upon by external impressions, and is less the creature of impulse than one in whom the first kind is predominant. The more a man's actions are the result of impulse rather than of reason, the more susceptible he is to external impressions, and therefore to suggestive treatment.*

This brings us to the question, Who are the best sub-

* He who obeys his instincts, and instantly knocks down a man who has insulted him (this being a purely automatic action), would thus be a better subject for hypnotism than he who deliberately calls a policeman and goes in for damages.

jects for the treatment, and how far is it applicable to the bulk of mankind?

The late Professor Charcot asserted that it is suitable, and indeed possible, only for hysterical subjects, and that hypnotism is a pathological condition, or induced neurosis. He divided the hypnotic sleep into three well-defined stages: (1) Lethargy; (2) catalepsy; (3) somnambulism; and contended that there is a regular sequence in these, and that, according to the will of the operator, one or other can be produced.

He obtained a state of lethargy by fixing the patient's eyes on a given point, or by gentle pressure on the eyeballs. This state resembles natural profound sleep, but is distinguished from it, and from all other conditions, by a characteristic feature—neuro-muscular hyper-excitability; *i.e.*, if one presses a nerve, the muscles supplied by that nerve will be put into action, and if a muscle is stroked or pressed, it will contract. Thus, pressure on the ulnar nerve will, in Charcot's subjects, produce flexion of the third and fourth fingers, adduction of the thumb, extension and separation of the first and second fingers. It passes into the second stage when the eyelids are opened: cataleptic rigidity may now be produced in a limb, and it may be bent or placed in any position. Moreover, emotions corresponding with the position are evoked. If the subject is put into a pugilistic attitude, his expression will become fierce and determined; if into one of prayer, he will wear the aspect of devotion. Moreover, if only one eye be opened, one-sided catalepsy is produced, and the other side remains lethargic. A bright light or sudden noise will also produce this condition, and in closing the eyes the subject falls into lethargy. The third stage is produced from the first or second by gently rubbing the top of the head, when the cataleptic condition will vanish, and other characteristics will appear, chief among which are abnormal acuteness of the senses, and obedience to suggestion.

Though I have completely failed to find these three

stages in any of my somnambulic subjects, and though the experience of most observers is of an equally negative character, I am not prepared to say that they do not occur in a few hysterical subjects without suggestion. Dr. Grazzini, of Florence, and Dr. Barwise, of Blackburn, tell me that they have elicited them spontaneously.

Drs. Liébeault, Bernheim, Beaunis, and others of the Nancy school, deny the existence of these three stages. They assert that their experience in treating hypnotically a vast number of patients leads them to the conclusion that nothing resembling them has been or can be evoked *spontaneously*. They consider, in fact, that Professor Charcot has introduced a new hysterical condition into the Salpêtrière, and that this has become, as it were, an institution of the place which every new-comer hastens to comply with. They support this assertion by showing that when they in their Nancy practice explained to hysterical patients the effects produced by Charcot, the three stages, never before manifested, were forthcoming. Bernheim has well said: 'Méfiez-vous de la suggestion;' and an English physician has given an equally sage warning: 'Take care, or you will find what you are looking for.'* Charcot thus entered the field weighted with a theory which he seemed unable to shake off. If one of his school is shown a broad-shouldered navvy or a sun-dried old soldier in a state of profound hypnotic sleep, and is asked whether this looks like a hysterical subject, he will reply that appearances are deceptive, and that the very process of hypnotizing has developed a latent condition of hysteria, or one analogous to it.† The dis-

* Braid was at one time misled into supposing that by touching the phrenological 'bumps' he produced corresponding effects. For instance, if he touched the 'bump' of Destructiveness, the subject immediately proceeded to hit out and to destroy whatever was within his reach; if that of Benevolence, he would give away his watch, purse, etc., to any bystander. The fact is, that the sense of sight (under the apparently closed eyelids), that of hearing, etc., are so abnormally acute in somnambulists, that the slightest hint of expression, voice or touch, is sufficient to evoke from them the desired response.

† The fanciful method adopted by Charcot to produce the hypnotic state may give rise to unexpected results. Some of his highly

coveries of Professor Charcot in physiology and pathology fully entitle him to the world-wide reputation which he enjoys; but the attitude he has chosen to adopt towards hypnotism is unfortunate. By attaching undue importance to *le grand hypnotisme*, as seen in his subjects at the Salpêtrière, and by ignoring what his school calls *le petit hypnotisme*, and confining his researches to hysterical cases, he has retarded the progress of rational hypnotism. Of the considerable number of medical men I have met who have attended Charcot's demonstrations, not one has looked upon hypnotism as more than a toy, and not one has adopted it for the treatment of disease; whereas all those I have met who have studied the subject at the cliniques at Nancy have been thoroughly convinced of the value of the treatment, and have adopted it into their practice.* To my mind, the great merit of Dr. Liébeault is that he approaches the subject with only one end in view—the relief of disease. If the theories he has deduced from observed facts (for every man who is not a mere empiric must hold theories) do not, after closer observation, continue to correspond with them, the theories are

---

'educated' subjects fall into a state of catalepsy if a bright light is suddenly turned full on their eyes, and by the action of this excitant a hysterical patient of his was lately taken *in flagrante delicto*. She had stolen into a room, gone to a chest of drawers, and actually placed her hand on a coveted photograph which she intended to abstract, when a bright ray of light shot through a chink direct into her eyes, and she remained entranced and motionless until she was discovered. (*Revue de l'Hypnotisme*, October, 1889.) I have never heard of the hypnotic condition being thus involuntarily and spontaneously induced when the Nancy method has been employed.

* Perhaps here I may be allowed to say that my own experience in this matter is a very pleasant one. It has been my privilege to demonstrate the Nancy treatment to a large number of medical men, and not only have they been kind enough to express appreciation of what they have seen, but they have practically shown it by at once trying the method in their own practices. Doctors are naturally only too pleased to adopt a new treatment which has been proved useful and which will help them to deal with many troublesome cases; but it requires to be presented to them in a manner free from mysticism and exaggeration. The enthusiasm the good Dr. Liébeault shows is a part of his character, and lends a great charm to his advocacy of hypnotism; but discretion is the better part for his followers, and I think they fully realize this.

thrown over, and not the facts, as too often happens. The Nancy school may therefore be called practical and therapeutic, in distinction from Charcot's, which is theoretical and experimental.

The following table, taken from Professor Beaunis's work, proves what a mistake it is to suppose that only hysterical persons are influenced by the treatment.

Patients submitted to hypnotization by Dr. Liébeault in 1880 (1,014):

Not influenced	27
Drowsiness	33
Light sleep	100
Heavy sleep	460
Very heavy sleep	232
Somnambulism (slight)	31
Ditto (advanced)	131
	1,014

Professor Beaunis shows as follows the percentage of the different stages of hypnotism at different ages:

	Somnambulism.	Very heavy sleep.	Heavy sleep.	Light sleep.	Drowsiness.	Uninfluenced.
To 7 years	26·5	4·3	13	52·1	4·3	—
7 to 14 „	55·3	7·0	23	13·8	—	—
14 „ 21 „	25·2	5·7	44·8	5·7	8	10·3
21 „ 28 „	13·2	5·1	36	18·3	17·3	9·1
28 „ 35 „	22·6	5·9	34·5	17·8	13	5·9
35 „ 42 „	10·5	11·7	35·2	28·2	5·8	8·2
42 „ 49 „	21·6	4·7	29·2	22·6	9·4	12·2
49 „ 56 „	7·3	14·7	35·2	27·9	10·2	4·4
56 „ 63 „	7·3	8·6	37·6	18·8	13	14·4
63 and above	11·8	8·4	38·9	20·3	6·7	13·5

These statistics refer, of course, to Nancy, and, as has been already pointed out, that town is pervaded by an atmosphere of hypnotism and suggestion. But Dr. Van Eeden assures me that at Amsterdam he finds the proportion of the 'uninfluenced' but little larger, and the ex-

perience of Moll in Berlin, Wetterstrand in Stockholm, Bramwell, Kingsbury, Cruise, Woods, and other observers all over the world, is of a similar nature. The proportion of somnambulists, however, is undoubtedly much greater at Nancy than we could expect to find it in England. Among over 500 patients I found only about fifty.

And here a word on the subject of somnambulism. Though Dr. Liébeault and his followers do not seek to enforce the somnambulic state, but find a state of gentle lethargy or drowsiness sufficient for ordinary curative purposes, he considers that it is well to induce in the patient the most advanced state of hypnosis to which he is susceptible; for the more complete the hypnosis, the less liable are the patient's morbid auto-suggestions to interfere with the curative processes. Natural somnambulism is nearly always associated with mental or bodily weakness, but the artificial variety is not dependent on defective health, mental or physical. Private soldiers and agricultural labourers are not generally considered neurotic, but they are 'good subjects' for hypnotism, and a large proportion—perhaps a fourth—will be found to become somnambulic.

Strong muscular and intelligent men and women are, in my experience, the best subjects for hypnotism. This was what Dr. Hugh Wingfield found when he was assistant demonstrator of anatomy at Cambridge. He experimented on a great number of undergraduates, and the majority of them proved extremely good subjects. A few years ago, during a visit to the University, I was asked to hypnotize a party of undergraduates in a friend's rooms. Ten out of twelve were easily influenced, two or three to the extent of somnambulism. Now, we know that these young men constitute the pick of the nation, intellectually and physically, and such experience proves the fallacy of the contention which one sometimes hears urged against hypnotism, that it is only applicable to fools and weaklings.

I understand that persons who make a public show of

hypnotism always express a preference for muscular subjects. Probably strong healthy people are more trustful and less fidgety than the weak and neurotic.

But I think the most interesting psychical results are likely to be achieved with neurotic subjects whose nervous systems are highly strung. I am not, however, at all sure on this point, seeing that some of the most interesting series of experiments in advanced hypnotism, including thought transference and second personality, have been made by Professor Janet of Havre with a strong-framed fisherwoman as the subject; and the Brighton experiments of the Society for Psychical Research were made on a young healthy tradesman.

Somnambulism is not an essential product of hypnotism, and, interesting though its phenomena may be from a pathological and psychological point of view, they are no more a part of suggestive treatment than an exhibition of the poisonous effects of drugs is a part of ordinary medical practice. They help to elucidate points in the treatment, and therefore must be studied, but experimentation upon them is outside the scope of the physician, as such.*

* See Appendix. Hypnotism being a new thing in England. the knowledge of it seems chiefly confined to theory, and one has to hear many fanciful and exaggerated statements. For instance, in an article on the subject in the *Saturday Review* of December 8, 1888. *à propos* of a paper of mine in the *Nineteenth Century* for December, the writer, evidently a medical man, states that a person once hypnotized is at the mercy of the operator, who can repeat the operation at will, even without the consent of the patient. Further, that anyone can easily hypnotize a person who has once submitted to hypnotism; and again, that a person once hypnotized is unable to look people in the face without feeling an irresistible desire to sleep. I have made inquiries among my patients of both sexes, some of whom have been hypnotized many times, and have fallen into the profounder degrees of sleep. They can all certainly look me in the face for any length of time without feeling in the least degree sleepy; and they all tell me that until they entirely give up their minds to the operation no soporific effect is produced. Most misleading conclusions have been drawn from exceptional cases, such as that of the 'Soho sleeper.' These belong in no sense to hypnotism as a therapeutic system, but are examples of hysteria. Constantly hypnotizing a weak-minded person for experimental purposes will probably bring about a morbid state of brain, and such abuse of a therapeutic agent can only be deprecated and discouraged.

CHAPTER V

Psycho-Therapeutics not an exclusive System of Treatment.—Some Diseases found to benefit from it.—Organic processes affected by Hypnotic Suggestion.—Blisters and *Stigmata* so caused.—Treatment especially useful in Neurotic Diseases.—Hysteria, Hypochondriasis, Dipsomania, and the Opium Habit.—Moral Depravity.—Double Consciousness.—Permanence of Cures.—Hypnotism distinct from Magnetism.—Possible Abuse of Hypnotism not a Bar to its Use in Medical Treatment.—Restrictions and Precautions necessary.

We are now in a position to speak of suggestion as a mode of treatment and cure, and we will first consider to what class of diseases it has hitherto proved applicable. And here I may say that, although Dr. Liébault rarely gives medicines, but obtains most of his remarkable results by the suggestive treatment pure and simple, his followers by no means dispense with those remedies which the researches of generations of able men have put within their reach. In suitable cases they make use of dietetics, drugs, electricity and massage, and the combination of those means with suggestion often gives better results than any one method of treatment.

The suggestive method is especially applicable to chronic complaints. Rheumatic and gouty pains often yield to it, as do also many diseases of malnutrition, such as anæmia and 'general debility.' In derangement of the functions in women it acts very beneficially, both in checking excessive loss and in promoting a proper flow; also in relieving or curing periodic sufferings of all kinds. In chronic constipation and diarrhœa it has excellent effects, and patients usually find that the intestinal functions become regular through its use. Indeed, therapeutic

suggestion gives a healthy tone to the organic system generally, and tends to regulate all its functions. A consideration of the experiments of Bernheim, Delbœuf, and others will render this statement more comprehensible than it may appear on the surface.

Suggestion is extremely useful in cramp from the overuse of certain muscles, such as is commonly found among writers and telegraph clerks. It is very successful also in some cases of old-standing paralysis, and especially so in the infantile variety. Many practitioners speak highly of its curative power in nervous affections of the eyes, *e.g.*, hysterical amaurosis, and it is found beneficial in a few forms of deafness. In fact, whenever we find chronic disease resisting the usual methods of treatment, suggestion may be thought of as a useful ally.

Perhaps some readers will consider the scope here given to suggestion too wide, but I am convinced that its intelligent use by the medical attendant will be found beneficial in many cases where drugs do not act satisfactorily, or to reinforce the action of drugs. For instance, it may be desirable to give ipecacuanha, but the retching following its administration may render its use impossible at an important time; or a mild cathartic may induce colic, often half imaginary; in such cases hypnotic suggestion may be useful to calm oversensitiveness. In how many diseases, such as typhoid and rheumatic fevers, are the attendant weariness and restlessness among the most distressing symptoms! These may often be relieved by this treatment, which is here advocated, not as a speciality, but as an auxiliary in practice to every medical man. Professor Bernheim uses it practically for every case in his wards, and finds it of immense value in calming nervous excitability, improving general nutrition, and producing refreshing sleep. Dr. Myers relates how Bernheim hypnotized a patient who was brought into his wards suffering from pneumonia, accompanied with delirium and sleeplessness. The man slept quietly for two hours and awoke refreshed, fairly comfortable, and

free from delirium. The physical signs of consolidation were the same after as they were before the sleep, but the attendant suffering was very greatly modified.

Sir T. Lauder Brunton tells how he saw Liébeault treat a case of bronchitis. He hypnotized the patient, and suggested, 'You will have no more pain, no more spit, no more cough, when you wake up.' Dr. Brunton adds when the man woke up he had less pain, less cough, and less spit (*op. cit.*, p. 232).

When I was attending Liébeault's clinique, the only patient he did not try hypnotism on was a boy suffering from scabies, and for him he prescribed the usual sulphur ointment.

The sick and those reduced in strength are exceptionally good subjects for hypnotic suggestion, and therefore offer a particularly favourable field for its employment. In many chronic cases it seems to give the patient a fresh start, and puts the system in a condition favourable to the action of other remedies—such as massage. I am certain that it will, in many instances, be found a valuable adjunct to the Weir-Mitchell method, and will supply the mental and moral element which is sometimes required in this treatment. Some patients are irritated rather than soothed by massage, and for these hypnotism will act as a preparatory step. Several well-known physicians, speaking to me on the subject of hypnotic suggestion, have told me that they find *suggestion* sufficient in their practice, without *hypnotism*, and have given several instances in which pseudo-paralysis and hysterical troubles generally have yielded to their well-timed assurances.*

* Professor George Buchanan, of Glasgow (*Lancet*, June 20, 1885), records two cases treated by him by simple suggestion without hypnotism. The first patient, a lady who had been bedridden and unable to move for months, was supposed to be suffering from spinal disease. Dr. Buchanan had but just returned from a visit to Lourdes, where he had been much struck by the 'miraculous' cures of nervous complaints closely simulating organic disease. He formed the opinion that this was a case of hysterical pain and paralysis, and he assumed a confident manner, and told the patient to turn on her other side. She did so, and he gradually got her out of bed ; and before he left

But I maintain that if simple suggestion can work thus beneficially, its effects must be greatly increased by hypnotism, and that with this aid it will sometimes produce results which it would be impossible for it to achieve alone, even in the most able hands. It is, as I have said elsewhere, through unwonted concentration of the imaginative powers upon a given point that suggestion works, and for most persons intense concentration is difficult—indeed, almost impossible to attain to in their normal state. Sir James Crichton Browne, in his eloquent address before the British Association at Leeds, in 1889, laid particular emphasis on the important rôle played by the imagination both in health and disease, and begged his audience to employ this power and direct it into proper curative channels.

Dr. Liébeault strongly recommends the treatment for sprains and muscular strains. In such cases it may be combined with gentle massage of the injured part. In the acute stages it may relieve pain and quicken the natural processes of repair, and in chronic cases it seems to aid in

---

the house she was able to walk about the room, and was free from pain.

The cure (Dr. Buchanan adds) appears permanent, for she was quite well eight years afterwards. The other case he cites is one of 'hysterical knee,' which had been diagnosed and treated as disease of the joint. After a little manipulation he told the patient that she could walk, and she was at once able to do so, though the slightest movement previously had caused intense pain. These cases are very similar to many reported by Bernheim and others as having been cured by hypnotism, and they are, as Dr. Buchanan says, among the most intractable complaints which medical men are called upon to treat, the disorder being in the imagination, and not in the part which appears affected.

The beneficial and curative action of suggestion is not confined to bodily ailments. We are all acquainted with numerous examples of cases where a 'word in season,' *i.e.*, a suggestion falling on a receptive soil, has so influenced moral conduct that it has changed the entire life of the individual.

The eloquence of Father Mathew and Gough, the temperance advocates, produced many as wonderful conversions of drunkards as hypnotic suggestions can ever claim, and though a proportion of these were but temporary, others were both sudden and permanent. The history of all religious revivals abounds with instances of sinners being reached by suggestion under special circumstances of preparedness, who would never have been touched by ordinary preaching.

absorption of any exudation or deposit which may have formed. The rapid relief of pain and restoration of movement in some of these cases must be seen to be believed.

In cases of 'railway spine,' and of disorders resulting from shock and concussion generally, it affords hope of relief and cure; and in such cases the patient should be allowed to remain in the hypnotic state for a considerable time, as the rest to the nervous system and freedom from pain and irritation are, no doubt, important factors in the cure. There is no question of the value of suggestion in the treatment of such nervous conditions as insomnia and hysteria, and of such diseases as require above all things mental calming and repose. It is often impossible in many cases of chronic disease to say how much of the suffering depends upon organic disease, and how much on reflex disturbance and functional derangement. This is well seen in diseases of the heart, where often the distress of the patient is quite out of proportion to the amount of lesion. In such cases the neurotic symptoms may often be relieved by hypnotic suggestion.*

The use of hypnotism as a means of diagnosis should not be overlooked. Dr. Hamilton Osgood (*loc. cit.*) was enabled by its employment to discover the functional character of a paralysis which had been previously looked upon as of organic nature.

Its power over the organic processes has been clearly shown by many experiments, made either on students of the system or on patients, with their own previous consent. A patient in the hypnotic sleep is told that he has burnt his hand or some other part of his body; he not only feels heat and pain in the place indicated, but it frequently happens that the spot becomes red and inflamed, and exhibits all the objective signs of congestion, and even of inflammation, vesication, etc. The suggestion of the operator has, through the patient's imagination, been

* On this point I would especially refer the reader to Dr. Buzzard's Presidential Address to the Neurological Society, 1891 (republished in book form). He clearly shows how fine are the differences between 'functional' and organic diseases of the nervous system.

able to affect the vaso-motor functions of the sympathetic nervous system. This experiment and others of a like nature open up a wide field of pathological interest; for if suggestion can cause an increased flow of blood to a part, and local congestion and inflammation, can it not also dissipate and cure these conditions when they occur in disease? Clinical experience answers in the affirmative.

Professor Delbœuf, of Liége, desiring to ascertain the positive effect of hypnotic suggestion in the treatment of a burn, and being, of course, unable to find two persons of identical constitution and condition generally, used the ingenious device of producing, with caustic, two exactly similar burns on the same person—one on each arm—and of treating one wound by curative suggestion, combined with the usual remedies, and the other with the usual remedies only. Having induced hypnotic sleep, he suggested to the patient that the one arm should be cured painlessly and without any suppuration; and it did in fact heal, by simple separation of the slough and healthy granulation, ten days earlier than the other, which went through the suppurative process, accompanied by inflammation and pain (*op. cit.*, p. 9). Were this case not reported by a well-known *savant*, I confess I should feel some hesitation in recording it here; as it is, its accuracy is beyond doubt.

Professor Beaunis (*op. cit.*) notes a case in which, by suggestion, he regulated the pulse of a patient. Before sleep there were 96 pulsations in a minute, which during the sleep increased to 98·4. He suggested a reduction, and it fell to 92·4. The pulse having again risen to 100·2, he suggested an acceleration, and it further rose to 115·5. The slackening and quickening of the pulse in each instance followed immediately upon the suggestion. The tracings were taken by Marcy's sphygmograph, and of these facsimile reproductions are given in Beaunis's work. He also succeeded in slightly raising the temperature of patients by suggesting an increase of warmth.

I have myself frequently succeeded in modifying the heart's action by hypnotic suggestion to a notable extent by as many as 10 beats in either direction in the minute, but the subjects on whom vesication can be produced by suggestion are, I imagine, very few, and in them probably only after prolonged experimentation. I have on one occasion produced vomiting by suggestion. The patient, a dipsomaniac, who had relapsed and indulged in beer, required, I felt, very drastic treatment. He was a somnambulist, and in the trance state I told him that if he ever drank beer again it would act as an immediate emetic. I then awoke him and insisted on his drinking half a glass of ale. He had hardly swallowed it before it returned, though he was quite unconscious of the suggestion.*

Beaunis describes at some length the production of all the effects of a blister following the suggestion that one had been applied. ' M. Focachon, a chemist of Charmes, showed us (Drs. Bernheim, Beaunis, and Liébeault) this phenomenon on a patient whom he brought to Nancy. During her sleep, at about 11 a.m., eight postage stamps were applied to her left shoulder, while it was suggested to her that they were a blister. She was allowed to sleep all day, being, however, aroused for meals, and was kept under observation. When she retired for the night she was told to sleep until 7 the next morning. At 8.15 a.m. the dressing which had been put on was removed, and the stamps were found *in situ*. The surrounding skin, for four or five centimetres, was thickened, modified, and of yellowish-white colour. The cuticle, however, was not raised, and did not form a blister; but it was thickened and wrinkled, and presented the appearance usual before

* I have since received letters from this gentleman's friends, and what they say affords remarkable evidence of the deep-seated effect of hypnotic suggestion. A short time since he was taken suddenly ill at a cricket-match with what turned out to be acute pleurisy. As he was faint and in pain, he was given the usual rough-and-ready remedy—a glass of spirits. No sooner had he swallowed it than it returned. It was three months since I had last hypnotized him, but Dr. S—— had repeated my suggestions.

complete vesication. The part of the skin was surrounded by a zone of intense redness and swelling.* M. Focachon and the patient returned to Charmes, and by 4 p.m. four or five vesicles were developed. Fifteen days later the blister was still suppurating freely. M. Focachon made a similar experiment on another patient, and in forty-eight hours produced a blister, which followed the same course.' The converse experiment has also proved successful. A blister is applied to a hypnotized subject who is told that it is a soothing liniment, and no vesication is produced (Alfred Fouillée, *Rev. des Deux Mondes*, May, 1891).

Professors Bourru and Burot, of Rochefort, succeeded in causing hæmorrhage from the nose, by suggesting that it should take place, in a young soldier of epileptic and hysterical constitution; they even fixed the hour when it should come on. On this same subject Dr. Mabille, of the lunatic asylum at Lafond, produced instantaneously, by suggestion, hæmorrhage from different parts of the body, exactly similar in character to the *stigmata* of some medieval saints.†

Professor Krafft-Ebing, in his remarkable monograph on the case of Ilma Szandor, a young Hungarian girl of extremely hysterical type, gives an account of many experiments he performed on her. He was able by simple suggestion to produce blisters and hæmorrhages and to effect marked alteration in temperature and in the character of the pulse and respiration.‡

The temperature experiments of Krafft-Ebing with Ilma

* Sir B. W. Richardson, in his kindly notice of my book in the *Asclepiad*, June, 1890, attributes the blisters produced in this case, not to suggestion, but to the fact that the gum on the postage stamps was of bad and irritating quality! Dr. Albert Bonjean (L'Hypnotisme ses Rapports, avec le Droit et la Thérapeutique, Paris, 1890) relates numerous experiments in which he was able to obtain stigmata and blisters by suggestion alone, without even touching the part affected.

† The best modern example of a religious *stigmatisée* is that of the Belgian nun, Louise Lateau. The case was very fully investigated in 1869 by Dr. Lefébvre, Professor at Louvain University, and other physicians, who came to the conclusion that the phenomenon was a genuine result of auto-suggestion. (Bonjean, *op. cit.*, p. 106.)

‡ *Op. cit.*

Szandor seem to have been confined to causing decrease of temperature—no doubt as affording the most striking evidence of the power of suggestion. At a meeting of the Medical Union of Vienna in December, 1887, he hypnotized her by friction of the forehead, and suggested that her temperature should fall to 35·5° C. Immediately before the operation the temperature was 37° C., and immediately after it (at 8 p.m.) it was 37·1°. At 9.30 p.m. it was 36°. Next morning at 8 a.m. it registered 35·9°, and at noon it was 35·7°. It remained at this subnormal height until her next hystero-epileptic attack. The experiment was repeated on several occasions, and the fact was demonstrated that not only could the temperature be lowered by hypnotic suggestion, but that its height at a fixed hour could be arranged by suggestion. Truly an extraordinary phenomenon. Professor Preyer, commenting on it in his admirable work, says he can see no way to account for the extraordinary changes of temperature except by admitting that intense ideo-conception processes in the cortex can under certain conditions act upon certain heat centres. He is disposed to doubt the continuance of the action, and supposes that the application of the thermometer revived the suggestion each time it was used, and that the effect being produced and the instrument withdrawn, the temperature would rise to its normal level, and would continue at it until a repetition of the operation led to a repetition of the suggestion and its realization (*op. cit.*, p. 73). It must be remembered that Ilma Szandor was altogether an exceptional subject, and that Beaunis experimented over a considerable period of time without being able in any case to obtain more than a fractional rise. The fact, however, that an agent only produces its most extreme effects in persons of rare idiosyncrasy does not take from the importance of its action, and enables us to understand the slighter effects produced on ordinary mortals.

In Binet and Féré's 'Animal Magnetism' (Kegan Paul, Trench and Co., London, 1887), the above and several

other similar experiments are related; for instance, how Dumontpallier succeeded in raising the local temperature several degrees, and how Bourru and Burot wrote his name with the blunt end of a probe on both arms of a hysterical male patient, suggesting to him, 'This afternoon, at four o'clock, you will go to sleep, and blood will then exude from your arms in the lines which have been traced.' The patient fell asleep at the appointed hour, and the letters appeared on his left arm, marked in relief, and of a bright red colour, with here and there minute drops of blood. But no such sign appeared on the right arm, which was paralyzed.

Charcot (the writers go on to say) and his pupils at the Salpêtrière have often, by means of suggestion, produced the effects of burns upon the skin of hypnotized patients (pp. 198, 199). Féré adds that he has demonstrated that any part of the body of a hysterical patient may be made to change in volume by simple directed attention, thus showing what influence may be exerted by a simple phenomenon of ideation on the vaso-motor centres.

Binet and Féré cannot be accused of undue credulity. They refuse to accept as proof any phenomenon which has not been subjected to the most searching scientific tests; and they are so imbued with the theories of Professor Charcot, that they fail to see the therapeutic applicability of hypnotic suggestion, except in hysterical cases.

I have made a few experiments to test the length of time during which a suggestion of sensory illusion continues to act, and I have generally found that a night's sleep puts an end to it. But this is not always the case, and Mrs. S—— has on several occasions remained under the suggested delusion for several days. For instance, I once hypnotized her and told her that her favourite cat, a tabby, had a black tail, and that it would continue so for three days. On awaking, she no sooner saw the animal than she described the change which she noticed had come over it, and she expressed a fear that it was ill;

when at the end of three days it assumed its natural colour to her eyes, she expressed her relief at seeing it recovered. A gentleman, to whom I have sometimes suggested visual hallucinations, sticks to the assertion that a colour is what I have told him, but he does so in a somewhat shamefaced manner, as one conscious that there is something not right about it. So one gets all grades of effect, from complete sensory hallucination to merely increased credulity.

The effects of suggestion are not necessarily temporary and immediate, but may be caused to appear hours, days, and in some cases months, after the suggestion has been given. Bernheim cites several instances of this prolonged or deferred action, applied to the physical or psychical side. Under the physical heading I should place the production of such an objective symptom as a blister or ecchymosis, and under the psychical a sensory impression, such as the appearance of a hallucination at a given hour, or the performance of a suggested action after a certain interval. For instance, a soldier, a patient of Dr. Liébeault, while in a state of hypnotic somnambulism, was told that on a certain day in two months' time, at ten o'clock a.m., he would come to Dr. Liébeault's consulting-room, and would there see the President of the Republic, to whom he would make a profound obeisance. The President would then advance towards him, would address him in complimentary language, and confer upon him a decoration, which he himself would fasten to the recipient's buttonhole. On the day appointed a considerable audience, consisting both of doctors and patients, was assembled in the consulting-room, and at ten o'clock precisely the soldier appeared. As he entered his expression changed; he regarded the bookcase, and bowed low in its direction. He then advanced, bowed to Dr. Liébeault, and stood at attention, with a gratified smile on his face, and looking downward at his buttonhole. In a few moments he made another profound obeisance, muttered some words and walked away, much to the astonishment of those present,

who were ignorant of the meaning of this pantomime.*

Dr. Beaunis tells a similar story of a young woman whom, while she was in a profound hypnotic state, he assured that on the following New Year's Day she would see him enter her room, and would hear him say, 'Bon jour, mademoiselle.' This suggestion was made in July, and on the following 1st of January the young woman wrote to the doctor, saying that she could not understand how it was that he had entered her room that morning, had greeted her, and then walked out immediately. She remarked further that he was dressed in the same clothes she had seen him wear in the month of July. At that time Dr. Beaunis happened to be in Paris, while the young woman was at Nancy.

Dr. Bramwell has made some interesting experiments on the estimation of time by somnambulists (*Brain*, 1898). His subject, a young woman, is told in the hypnotic state that after a given number of hours or minutes she is to perform a certain act. For example, she is to address an envelope to Dr. Bramwell at the expiration of 12,500 minutes from the moment she wakes up. When awakened she remembers nothing of the sitting, and goes about her usual work, but at the appointed time she executes the order, though perhaps it may be in the middle of the night, and she has to wake up for it, or she may be engaged in some absorbing work. It is a very interesting question what causes this response to time suggestions. It may be that the 'subconscious self' has a means of reckoning the moments as they fly. Perhaps the ratio of expiration is unconsciously noticed, and gives a clue to the passage of time. The conditions of modern life tend to suppress many faculties which exist in primitive man. The Australian savage can find his way through the pathless bush by an instinct which has been lost by the white man. There is a story of an imbecile youth who could always tell the time within a few seconds,

* Quoted by Binet and Féré, *op. cit.*, p. 245.

and I suppose he had the 'time sense' unusually developed, and, having nothing else to do, cultivated it as a speciality.

Deferred suggestions, like nearly all suggestions given in the advanced stage of hypnotism, are almost invariably followed by amnesia. The subject, when awakened, has no recollection whatever of the order received by him, nor will it recur to his consciousness until the moment for performance has arrived. If he is then questioned as to his motives for such an action, he will probably reply that he did it upon an unaccountable impulse which he could not withstand. In very rare cases indeed there exists for some time beforehand an impression that at a certain hour a specified act must be done, or a specified word spoken. Occasionally, too, the hypnotic subject may recognise the impulse as having been dictated to him by a past suggestion; but generally, as I have said, it will be regarded as quite spontaneous, and not to be accounted for.

Moll, in discussing this point, aptly compares the mental state of a subject to whom the execution of a past hypnotic suggestion at a certain time has been commanded to that of a person who has been given a letter to post, and who puts it in his pocket and forgets it until he is reminded of his duty by passing a post-office. He then automatically posts the letter, but very likely entirely forgets the action, and may be unable to recall it.

This illustrates the fact, which cannot be too cogently impressed on the reader, that hypnotism does not induce a new condition, nor work on perfectly novel lines to the extent which is often supposed, but that its effects have analogies in nearly all the waking conditions of life, and that it acts by intensifying and utilizing mental states which are abnormal in degree, but not unnatural in kind.

Such phenomena throw a strong light on many stories of supernatural apparitions, and show how useful hypnotism may prove in the hands of competent observers as a key to psychical problems. Here we find an idea

impressed on the 'unconscious mind,' and lying dormant for months, brought into action by the simple efflux of time, as certainly as a piece of clockwork can be set to run down at a fixed hour. I need hardly add that such experiments as the foregoing are successful only in a very small proportion of cases, and probably only in 'educated' subjects.

Fulfilment of a suggestion, the prompting of which has either not been consciously heard, or has been instantly forgotten, is not without its analogy in ordinary life. We must all acknowledge that we occasionally think, speak, and act in what seems a motiveless manner, and yet, by careful introspection or tracing back, we shall probably find that our thought, word or action has its source in some forgotten or apparently unnoticed incident, which has left its impression upon our brain cells. The brain cells, once stimulated, may under certain conditions, as in delirium, prompt the utterance of sounds apparently forgotten or unrecorded. Thus, we find persons on their death-bed, or in fever, speaking a language which they had forgotten since childhood; like an elderly Scotch physician, a friend of mine, who for an hour before his death talked only in Gaelic, the language of his childhood, which he had not spoken for fifty years.* There is a well-

* Some persons are, as Bernheim points out, 'suggestible' to an extraordinary degree, independently of hypnotism. This, he finds, is especially marked in children and in persons affected with phthisis. He relates how he has frequently suggested imaginary actions, and even crimes, to such subjects, with the result that the ideas have been accepted as true, and have become as actual truths to them. This increase in the normal suggestibility may perhaps serve to explain the extraordinary stories invented by some children. Such untruthfulness may not depend upon viciousness, but on excessive imagination, which has been set in action by some outside suggestion. Professor Déjerine speaking of suggestibility without hypnosis cites the case of two young countrymen under his treatment in the hospital. They were both fresh from military service when he first saw them, and neither of them had ever been hypnotized; yet he was at once able by simple suggestion to evoke in them sensory hallucinations, changes of personality, and all the other psychical phenomena which one is accustomed to associate with the most advanced stages of hypnotism (*Rev. de l'Hyp.*, Jan., 1891).

Anæsthesia by suggestion may be sometimes induced quite independently of hypnotism. For instance, Dr. Robinson, of the Mile End

known story of a servant-girl, who, in the delirium of fever, continually repeated passages from the Greek Testament, which her ears had unconsciously taken in years before, when she had been in the service of a clergyman. And all persons entrusted with the care of lunatics must know what unseemly and even vile expressions may, in the paroxysms of insanity, be uttered by young, refined and virtuous women, whose lives have been carefully guarded from evil influences. The vicious word or phrase heard by them long ago, perhaps in early childhood, while passing along a street, or standing at a window, though uncomprehended at the time, and apparently unremembered, was nevertheless recorded in the brain cells.*

It will thus be seen that suggestion is an exceedingly powerful agent—effective in the hands of the experimentalist, and efficacious also in those of the physician. When we consider that the knowledge of this treatment has only become general within the last fifteen years, we

---

Infirmary, found that he could induce complete anæsthesia and analgesia in a hystero-epileptic girl, who had never been hypnotized, by telling her she was to feel nothing. The girl had confidence in the physician, and his suggestion was in some way able to produce a condition resembling hysterical anæsthesia, probably by inhibition of the sensory centres.

* Dr. Felkin, in his very excellent résumé of the progress of hypnotism, gives an interesting experience of his own with a hypnotized subject. She was a woman of fifty, who could not in her waking state speak English, yet when hypnotized she began to talk fluently in English. It appears that she had known the language as a girl, but had entirely forgotten it, and that hypnotism brought back the girlish memory (*op. cit.*, p. 50).

A case reported by the Society for Psychical Research shows the extreme importance of very early impressions which may not have been registered in ordinary memory, and yet cause after-effects. A lady of early middle age was invariably haunted by a certain nightmare. This always took the form of being attacked and bitten by a great white dog.

The underlying cause of this dream was afterwards explained by an old nurse, who related that she had charge of the lady when an infant of about a year old, and left her asleep in a cradle in a room opening on to a garden. One day a strange white dog had dashed into the room, upset the cradle, and awakened the sleeping infant. No great harm had been done, but the impression made on the undeveloped cortical cells had never been eradicated. Suggestion, if the patient were a good hypnotic subject, would almost certainly remove the idea.

must acknowledge that its progress, and the number of diseases which it affects, are both remarkable. But we must also acknowledge that it is no universal remedy, warranted to act like magic on all diseases. In some cases it is powerless, or comparatively so. It cannot restore a joint altered by chronic rheumatism or gout, nor put right an internal misplacement, nor can it remove cancer or other malignant disease; neither will it cure paralysis agitans, glaucoma, advanced Bright's disease, nor diabetes. It cannot materially benefit cases of phthisis or organic heart disease, though it may do much to relieve the sufferings incidental to all painful affections. It has been but little employed in acute illness. I believe that most of the Continental practitioners of the system use it chiefly at consultations in their own rooms, where, of course, sufferers from acute diseases are not likely to present themselves. It is frequently used in childbirth with beneficial results, and in surgery it is often employed. No doubt most susceptible persons might be painlessly operated upon while under its influence, but, as a rule, the natural agitation of a patient before an operation would so distract his attention as to render hypnotism impossible, and a course of training would be necessary, which would involve much time and trouble; whereas chloroform and other anæsthetics are easily administered, and are commonly certain in their effect. Professor Bernheim uses suggestion in conjunction with chloroform, and finds that his patients take the anæsthetic better, and require a much smaller quantity, than when it is administered silently in the usual way. This is the experience of many chloroformists.

Some months ago I hypnotized a woman for a dentist instead of giving her gas, and a very bad tooth was painlessly extracted. The patient not only felt no pain at the time, but there was no discomfort afterwards. This dentist tells me that he now often uses hypnotism as an anæsthetic in his practice, and finds it extremely useful, as not only does the patient feel no pain, but he is able to

assist the operator by holding his mouth open without a gag, and spitting when told to. If he finds the patient is not hypnotizable, no harm is done, and he gives gas in the usual way.

Suggestion may be usefully employed instead of narcotics in temporarily relieving acute pain, by inducing sleep which will not be followed by the deleterious consequences of such drugs. It is also used in cases where the sleep itself is remedial, as in threatening congestion of the brain, delirium tremens, and in insomnia, when this exists as an independent condition, and not as a symptom of disease.

But it is in the so-called 'neuroses' that suggestion obtains its most brilliant successes—in functional epilepsy, St. Vitus's dance, asthma, palpitation, nervous headache, spinal irritation, neurasthenia, ovarian pain, and the many forms of dyspepsia. Nervous disease is, unfortunately, ever on the increase, and the study of its symptoms, its cure and prevention, must increase to keep pace with it. As civilization advances, humanity develops 'nerves,' which in this sense may be said to have no existence in the savage and barbarous states. The vices and virtues of civilization tend alike to increase our sensitiveness. Drink, narcotics, the abuse of tobacco, social excitements, intellectual culture, the ever-spreading desire to be or do something remarkable—these and many other stimulating influences are perpetually at work to promote nerve disease among us. In large cities especially, where men live under artificial conditions and at high pressure, we find in all classes of the community affections presenting subjective symptoms quite out of proportion to the objective signs. It would be interesting to ascertain what proportion neurotic affections bear to organic diseases in a city doctor's day's work. Probably one half at least. Many of us when fresh from the hospital are vexed and surprised to find how much of our practice is made up of such cases. They are really among the most painful and difficult complaints a physician is called upon to treat,

for they generally indicate a weak and depressed state of vitality, in which the slightest suffering is felt with intensified force. Take the medical nomenclature ending in *algia:* cardialgia, cephalalgia, gastralgia, myalgia, neuralgia—what visions of suffering do these words call up!

Hysteria, and many other neuroses, are popularly supposed to be essentially the diseases of the rich and idle, but Dr. Savill has shown that a considerable proportion of the cases in workhouse infirmaries are of this nature. This is what the physiologist would expect. Probably nothing is so fruitful a predisposing cause of neurotic ailments as intemperance in the parents, and the children of slum dwellers are sent into the world with such unstable nervous systems that those who manage to survive infancy are the special prey of all varieties of neuroses, and become the permanent tenants of workhouses and infirmaries. I have not been much impressed by the results of hypnotic treatment in a large proportion of these cases, and I have attributed its failure to the fact that there is a total absence of material to work upon. There is no reserve of nerve energy, as Dr. MacFarlane says of some cases of neurasthenia.

There is one class of cases for which hypnotic treatment offers particularly good prospects of relief. The exhausted brain-worker, whose nervous system is in a painful state of erethism, will here find exactly the remedy which is physiologically indicated. He is suffering from functional derangement of the highest centres, and the action of hypnotism on those is their reduction to a condition of physiological rest. The overwrought and overanxious victim of modern economical and social conditions can be soothed and refreshed, by hypnotic suggestion, to an extent quite unattainable through drugs or physical treatment of any kind. But hypnotization of these subjects is a process requiring much tact and patience—for the condition of the brain is such as to render the necessary mental quiet and confidence difficult of attainment.

Perseverance will, however, generally be rewarded by success, and success here often means new life to the sufferer.

Though such affections often depend upon organic disease, they more frequently have their source in nerve irritability and functional weakness. How they perplex the able practitioner, who feels quite at home with a case of scarlet fever or inflammation of the lungs! Nervous diseases generally—hysteria and hypochrondriasis in their many forms—are spoken of contemptuously by some pathologists, who are impatient of subjective symptoms which have no apparent objective reason for existence. It is natural to ascribe to imagination an ailment for which neither friend nor physician can find any comprehensible cause, yet these so-called fanciful ailments may be as real as typhus, and entail a thousand times more suffering on the patient. Bodily weakness, unaccountable pains, depression of spirits, a weight of misery accompanied by the conviction that no power on earth can lift it, a sense of being neglected by friends, or of being to them a weariness and trouble—all these sufferings of mind and body are real enough and hard to bear, whatever their original cause may have been.

I have recently (1899) seen a case of this kind. The patient is a professional man aged thirty-seven. He had separated from his wife from incompatibility of temper, and had lost nearly all his money. He got attacks of rage almost amounting to mania on the least contradiction or provocation, and at other times was intensely depressed, and often suicidal. It did not seem a very hopeful case, as suggestion could not bring back his money, nor render him and his wife suitable partners. But I tried it, and it succeeded in making him take a philosophical view of the situation. He now leads a rational life, works hard, and succeeds in forgetting his troubles. There is no doubt but that hypnotism has saved this gentleman from madness or suicide.

A somewhat similar case came under treatment about

the same time. This patient is an accountant who had broken down from overwork and business worry. He had been a good deal to blame, and was tortured by exaggerated remorse. He had been sent a voyage round the world, but *cœlum, non animum, mutant, qui trans mare currunt,* as the Latin grammar tells us, and he returned no better. Resumption of work was followed by a very bad nervous breakdown, and he was induced to try hypnotism. Though but slightly susceptible, suggestion soon told upon him. He has lost his morbid fancies, regained his power of work, and has been actively engaged in his business ever since. Loss of sleep is the first symptom of breakdown in these cases, and it is one of the first to be corrected by suggestion.

There is no doubt that these troubles are sometimes brought about by the patient's own fault. They may spring in the first instance from indulgence in bad habits, from idleness, from a tendency to foster and dwell upon morbid ideas; in short, they frequently are diseases *caused by the imagination,* which is quite a distinct thing from *imaginary diseases.* Indeed, there *is* no imaginary disease; he who persistently imagines a disease in himself *has* one, though possibly not the one he imagines. For the imagination which can furnish its owner with a bodily disease is itself not in a state of health. Who with healthy, well-balanced mental powers could or would bring upon himself a sickness by auto-suggestion? 'No one can be a hypochondriac at pleasure,' aptly says Lavègne.

'When one of these hypochondriacs,' writes Binet and Féré, 'whom we are apt to call *malades imaginaires,* comes to seek the help of medicine, complaining of subjective pains and uneasiness, what do we often reply? "It is nothing; it is merely fancy; try not to think about it;" and he is sent away with some anodyne or simple remedy. This invalid, who has suggested to himself his disease, and who really suffers from it, becomes convinced that it is not understood, and that nothing can be done for him. The more he trusts his physician, the deeper is this con-

viction; and he who came with merely a trifling complaint may go away with one which is practically incurable.'

The disease induced by morbid auto-suggestion may be controlled and cured by healthy suggestion from without, given when the brain is in a state peculiarly receptive of outer influence. The mind of a nervous, hysterical, hypochondriacal person is usually shut against all outward influence, except such as corresponds with and feeds its morbid state. The patient when awake rejects cheerful and hopeful suggestions almost as if they were insults, but in the hypnotic sleep, his morbid self-influence being temporarily in abeyance, his mind will admit and act upon suggestions of bodily and consequent mental cure.

Dr. Russell Sturges, of Boston, U.S.A., has reported an interesting series of cases which he has treated by hypnotic suggestion, and a somewhat singular part of his work is that he has gained success without putting his patient into the deeper stages of hypnosis. On the contrary, he contends that deep hypnosis is unnecessary, and sometimes even harmful. I confess such is not my experience, and that when I am asked if I can remove a morbid idea, I reply that it depends upon the patient's susceptibility to hypnotism. But, as Professor Pitres of Bordeaux points out, some people are more suggestible when awake than others when profoundly hypnotized.

Dr. Sturges, for instance, cites the case of a young lady who was a chronic invalid, and suffered greatly from internal neuralgia. There appeared to be no objective disease, but inquiry revealed that her ill-health dated from a mental shock she had sustained by an accident to her brother, brought on, she thought, through her fault. It appears she had urged her brother to ride a restive horse in spite of his protests. The horse threw him, and he broke his arm. Though he recovered, and was none the worse for the accident, anxiety and remorse so preyed on her mind that she became an invalid.

Dr. Sturges induced a slight state of hypnosis, and

suggested to her the correction of the morbid idea. The girl's friends had frequently argued the subject with her without effect, but three or four treatments by hypnotic suggestion brought about a right frame of mind and a corresponding cure of the bodily troubles.

Another case is that of a lady who quarrelled with her father immediately before his sudden death. She accused herself of being accessory to it, and fell into a state of chronic melancholia. Dr. Sturges succeeded in getting rid of the exaggerated idea, and restoring her to happiness and health.*

Professor Gibert of Havre reports an even more striking case of a young woman who was brought into the hospital suffering from paraplegia and profound disturbance of the digestive and generative functions. She had been hypnotized, and was a good subject, but the result had been disappointing. Investigation into the history of the case showed that the girl had sustained three great shocks in her life: the first when, at the age of seven, she had been forced to occupy the same bed as a child with a bad skin disease; the second just at the age of puberty, when she was put into an icy cold bath; and the third when she was terrified by seeing a woman killed by falling from a window. It was after the third shock that the paralysis developed, but it found her weakly and hysterical. Dr. Gibert threw her into a state of profound somnambulism, and then gradually worked at removing the domination of the morbid ideas. He gave a less serious turn to the events which had so influenced her life, and got her to look back upon them without terror. The result was complete cure in a few sittings.

One of my early hypnotic cases was that of a lady who had nursed a relative in his last illness. It was a very trying time for her, as he allowed no one else to attend him. One of her duties was to play to him, and in this he took great delight. Shortly before his death, in a

* 'The Use of Hypnotism to the First Degree as a Means of modifying or completely eliminating a Fixed Idea,' Boston, 1894.

paroxysm of jealousy he made her promise that she would never touch the piano after his death, assuring her that if she broke her word he would appear to punish her.

The peculiarly distressing circumstances produced an attack of nervous prostration, and when this passed away it left her with spasmodic asthma, which was new to her, choreiform movements of the head, night terrors, and intense nervousness, so that she was unable to travel or to face crowds. But the thing which most distressed her was her inability to listen to music, which had been the passion of her life, and she could hardly look at a piano without a nervous paroxysm.

I hypnotized her, and she passed readily into a condition of profound somnambulism. Then I suggested the disappearance of the morbid ideas, and with them of the nervous symptoms. Gradually the suggestions worked, and finally I got her with much difficulty to play on the piano while hypnotized. She left me cured of her asthma and spasmodic movements, and with her nervous system so strengthened that she could ride and drive again and go into society. She was able to listen to music, but showed a great disinclination to play herself. A little more treatment would probably have completely cured all the symptoms, but she had to go abroad, and I lost sight of her.

In these cases correct diagnosis and judicious treatment are the essentials of success. One has to unravel, as it were, a tangled skein, and rough treatment would probably aggravate the trouble. One knows that diseased conditions caused by shock are sometimes cured by another shock, as in cases cited on pp. 11, 12; but the gentler method of induced hypnosis and applied suggestion is at once more pleasant and more likely to succeed. I think it will be found that a much larger amount of chronic illness is due to shock than is generally recognised, and I know of no higher duty of the physician than the curing of such cases. The study of hypnotism and the curious features it brings to one's notice often gives a new interest

to ordinary practice, and throws a new light on the causation of an illness.

A recent case presents many points of interest. The patient was a weaver from the North, and he was sent to me by his clergyman. The poor man was unable to do his work, and suffered from sleeplessness, restlessness, mental depression, want of appetite, and other symptoms of neurasthenia. His illness dated from a year previous, when his son had nearly died from rheumatic fever. Quite unjustly he accused himself of being the cause of the illness, and nothing seemed to be able to get this haunting idea out of his mind. He proved a good hypnotic subject, and I sent him back in a fortnight quite well.

The suggestive system has been extensively taken up by foreign lunacy and mental physicians. Among these are Drs. Sémal, of the asylum at Mons; Mabille, chief physician of the asylum at Lafond; Burckhardt, of the asylum at Préfargier (Switzerland). These specialists and others frequently report cases of amelioration and cure, through the use of suggestion, in the *Revue de l'Hypnotisme*.

The insane are not easily influenced by hypnotism; all who have anything to do with them know how difficult it is to get them to fix their attention on anything except their delusion; but once an influence is gained over them, suggestion may prove most useful.

Dr. Woods, Superintendent of Hoxton House Asylum, London, is the chief worker in this field in England, and in an important paper contributed to the *Journal of Mental Science** he describes several cases of melancholia, delusional insanity and acute mania which he has benefited by hypnotic treatment.

That borderland of insanity occupied by dipsomania, the opium habit, and the excessive abuse of tobacco and other narcotics, offers an extensive field of usefulness to suggestive treatment. Professor Forel, of Zurich, in his address at the Congress of Neurologists, held at Zurich

* April, 1897.

in 1888, gave it as his opinion that in those cases suggestion is a very beneficial, and often a very powerful, agent, frequently enabling the drunkard to take that first step, which is always so difficult, towards reformation and cure. He cited also several cases in which he had succeeded by its means in curing patients of the opium habit in from eight to twelve days, and that without the acute mental suffering which is commonly felt when an enslaving habit is quickly broken off. Drs. Van Renterghem and Van Eeden (of Amsterdam) likewise tell me that they have had great success in overcoming these moral diseases. At Nancy I had the opportunity of seeing many such cases in process of cure. One man came to Dr. Liébeault completely shattered by indulgence in tobacco, which he both smoked and chewed. He was a railway porter, a big, strongly-built fellow, but he was weak and shaky through his excesses. His digestion was faulty, his tongue thickly furred, and he had no appetite. His pulse was slow and intermittent, he felt giddiness on movement, and his sight frequently vanished through incipient amaurosis. Persons whose nervous systems are broken down in this way are very easily hypnotized, and Dr. Liébeault soon had this man in a state of profound sleep. He then told him that he was to give up smoking, that a pipe was to be to him an object of loathing, and a quid of tobacco even more offensive; also that, if he did indulge in one or the other, pain and sickness would be the result, so that he must not even feel a desire for the indulgence. The patient came daily for several mornings, and daily showed an increasing improvement, till in a week he was completely cured of the symptoms of nicotine-poisoning. He would, of course, have been cured by voluntary abstention from tobacco, but I doubt if the beneficial effect would have been so rapid; and no one seeing the man would have credited him with the moral courage and determination necessary for breaking off a long-cherished habit. It is told of the younger Dumas that he was formerly an inveterate smoker, and on one occasion, feel-

ing out of health, went to consult his doctor with the usual cigar in his mouth. The physician, one in whom Dumas had entire confidence, having heard his symptoms, told him plainly that smoking was destruction for him, whereupon the great writer immediately flung away his cigar, declaring that he would never smoke another—and he has kept his word. But how many are gifted with such resolution?*

There are many cases on record where this abandonment of a cherished habit has been accomplished without hypnotism. A man who has caused the death of one dear to him in some drunken brawl is very likely, if he has any good in him, to conceive a horror and dislike for intoxicants, and to become a reformed character.

In many cases the good is thus so overshadowed and hidden by the evil that its presence is overlooked. Hypnotism, at any rate, enables us, under favourable conditions, to suppress the evil and thus give the good a chance of showing itself, and it is possible that it may even enable us to create good qualities in course of time.

In the *Revue de l'Hypnotisme*, 1886-1887, some papers appear by Dr. Voisin, of the Salpêtrière, showing the efficacy of suggestion in the treatment of moral obliquity; and at the Congress of the French Association for the Advancement of Science, held at Nancy in 1886, papers dealing with this subject were read by several physicians of eminence. Dr. Voisin gives instances of female prisoners, formerly considered incorrigible, who, after a course of suggestive treatment (combined with the re-

* A near relation of my own has recently been undergoing hypnotic treatment at Nancy, for the cure of the tobacco habit, and his experience is interesting. After being a great smoker for years, he formed the resolution of giving up the weed, as he found that it was causing nervousness and palpitation. Dr. Liébeault never induced in him more than a slight drowsiness, with inability to open the eyes, and yet the effect of suggestion was immediate and remarkable. Tobacco almost at once became distasteful to him, and he has never felt the least inclination to resume the habit. Probably in this case the patient would have been able to reform himself unaided: but Dr. Liébeault saved him from a good deal of suffering, and very likely from some relapses.

ligious and moral instruction, which alone had unfortunately proved ineffectual), became modest, cleanly, and industrious. Some of these reformed women have been placed in situations of trust, which they hold satisfactorily.

Many such cures are thoroughly authenticated, and the number of recorded cases is being rapidly augmented. In a most interesting article by Mr. F. W. H. Myers,* Dr. E. Dufour, the chief physician of the Saint-Robert Asylum (Isère), is quoted as follows: 'From this time our opinion is settled, and we have no fear of being deceived when we affirm that hypnotism can render service in the treatment of mental disease.' 'In common with most inquirers, Dr. Dufour finds only a small proportion of lunatics hypnotizable,' says Mr. Myers, 'but the effect produced on these is uniformly good. His best subject is a depraved young man, who, after many convictions for crimes, including attempted murder, became insane.' Dr. Dufour assures us that this difficult subject has become a reformed character through the influence of hypnotism.

Professor Forel, Medical Superintendent of the Cantonal Asylum at Zurich,† gives a case of reformation in a confirmed drunkard, seventy years of age, who, after twice attempting suicide, was placed under his care. He spent nine years in the asylum, during which he gave an infinite amount of trouble, drinking himself into a state of insanity whenever an opportunity offered, and inciting the other patients to rebellion.

In 1887 Forel hypnotized this apparently incorrigible subject, and treated him by suggestion. He proved susceptible, and after a few sittings became an utterly changed character. He proved his reformation by voluntarily giving up the small quantity of wine which had been allowed him, and joining the Temperance Society, which hitherto he had vilified and opposed. It was now safe to allow him full liberty, as the formerly attractive

* 'Multiplex Personality:' Proceedings of the Society of Psychical Research, vol. iv., 1886-87.

† *Op. cit.*

wine-shops were no longer any temptation to him. Dr. Forel adds, that during the last nine months he has been occasionally hypnotized for purposes of demonstration, but requires no furthur anti-alcoholic suggestion.

It is interesting to consider in this connection how far it is possible to modify inherited or acquired habits by hypnotism.

It is certain that suggestion has a twenty-fold greater influence in the hypnotic than in the waking state, and it is probable that many criminal and weak persons might be reformed by its continued employment. They would be educated or re-educated.

But I believe that the environment must at the same time be suitable, and that had Dr. Forel's patient been able to mix with his evil associates after each hypnotization, the good would have been checked in the bud by the excess of evil.

It is supposed that hypnotic suggestion causes inhibition, of psychical origin, of nerve tracts, and it is possible that it enables new nervous arrangements and combinations to be formed by directing nerve energy into new or little-used channels.

Association of ideas plays a very important part in all our sentiments and actions, and this association is certainly strengthened by hypnotism. This explains the success of the treatment in many cases of drunkenness. A good plan in these cases is to suggest dislike for alcohol, and even vomiting at the taste of it. If the patient is then made to swallow a small quantity and sickness follows, and he is told, while in the hypnotic state, that such will be the invariable consequence of indulgence, we shall have established a train of very disagreeable associations which will for a long time, and perhaps always, be connected with the first step in alcoholic indulgence. It may be objected that the association of a drunkard's ideas with alcoholism cannot naturally be pleasant, as excess is always followed by illness. But ordinarily sickness and disgust come *after* excess, while

hypnotism causes them to precede it. We frequently see the action of association of ideas where hypnotism is not in question at all. For instance, I know a lady to whom the taste of strawberry jam is most disagreeable and nauseating, because, as a child, on two or three occasions evil-tasting powders were given to her disguised in it.

The same lady tells me that the sight of a bottle from which she had been dosed with castor-oil used to arouse a feeling of nausea long after she had been emancipated from such compulsory medication. But similar instances are so common that they must occur to the mind of everyone.

Alcoholic intoxication is sometimes accompanied by distinct double personality, but this is rarely so well marked as in the case of a farmer referred to by Professor Ball. This man was a dipsomaniac, and frequently got drunk while attending the markets. In this state, however, he continued to transact business, and apparently with considerable judgment and ability. But on becoming sober he would be quite unconscious of what had taken place, and his business suffered severely in consequence. He hit upon the idea of keeping a note-book for use during his drunken state, and he found that by doing so he was able to preserve a written record of his operations, which supplied the hiatus in his memory ('Maladies Mentales,' p. 79). Oblivion of actions committed in a state of drunkenness is, of course, common enough, and there are plenty of cases on record where men have been hanged for murders of which those unhappy criminals had preserved no recollection. By special stimulation of the brain cells, alcohol may arouse the phlegmatic and dull-minded man to temporary brilliancy, and so induce what appears to be a change of character; but this change is generally more apparent than real. Alcohol, as a rule, does not change character, but emphasizes its features, though it sometimes effects very complete changes in a man's conduct. The penurious may become lavish, and the morose man may assume an air of jollity.

Here probably the alcohol acts by removing those inhibitory processes which are the result of education, and so allowing the natural characteristics free play. Hypnotic suggestion does not enable us to create force, but only to transform it, nor to create characteristics, but merely to modify them. I cannot think that hypnotism would make a naturally morose man permanently amiable, or a violent-tempered man quiet and gentle. But if the natural temperament has been altered by circumstances, or has not been allowed to develop, I see no reason why hypnotism should not bring out what is latent and suppress the acquired traits, and this applies especially in the case of children.*

In such examples one would say that there are two separate entities dwelling within a single bodily form, and that one of these can be brought out and developed, while the other is so absolutely suppressed as to appear non-existent. To some extent this is indeed the case with everybody. The best of us can feel a suppressed evil self struggling at times to get the upper hand; the worst are dimly conscious of some crushed-down better self striving within them—however rarely and feebly. It is

* The following extract from a letter recently received from an American lady is, I think, instructive in this connection. The writer, Dr. M. Goldson, of Oakland, California, came to London to attend the post-graduate lectures, and I gave her some instruction in hypnotism, which she is now turning to account in her practice: 'I have recently hypnotized a lady, Mrs. R——, who has been lately married. Her happiness was greatly marred by the conduct of her husband, who took the greatest delight in teasing her; the more she showed her annoyance, the worse he became. She took this so much to heart that she became profoundly depressed, and was continually in tears when alone. I hypnotized her, and suggested that she should no longer feel grieved or annoyed at his conduct, but should enter into his jokes with amusement, and should enjoy his merriment and be completely happy. The treatment was entirely successful, and after the fifth sitting Mrs. R—— reported that a complete change had come over her life, and that her husband was astonished to find that she no longer resented his jokes at her expense, but seemed rather to enjoy them.' It seems to me quite likely that if Mrs. Goldson had quietly talked to Mrs. R—— and given her sensible advice, the desired result might have been obtained; but no doubt hypnotism, by increasing the patient's mental receptivity, greatly aided the action of suggestion.

in a weakened or diseased brain condition that this psychological fact becomes startlingly manifest. Dr. W. Ireland* gives the case of a young man of good character, who, after an epileptic seizure, took possession of a carriage which he found in the street, drove to his father's grave a mile and a half away, gathered some flowers which grew there, and took them home to his mother. She was naturally alarmed at his conduct, and bade him take the carriage back to its owner; but instead of doing this he left it at a livery-stable in his own name. When he recovered his normal state of health it was found that he had no recollection whatever of this circumstance. On another occasion, again after an attack, he engaged himself as a sailor, but was soon found by his shipmates to be utterly ignorant of seamanship, and extremely strange and flighty in manner. In a short time he recovered his usual consciousness, and was amazed to find himself on board ship and far from land, for he had quite forgotten the series of events which had led him there. It would be interesting to see what view a judge would take of the legal responsibility incurred in such a case.

But far more remarkable are the cases of Louis V—— and Félida X——. The former is well described by Mr. F. W. H. Myers† (*op. cit.*). Louis V—— was born in 1863; his mother was a woman of ill-character, and, as a natural consequence, he fell early into evil ways. At the age of ten he was sent to a reformatory, where he showed himself docile and obedient. Four years later he was frightened by a viper, and this fright brought about a series of convulsions and hysterical attacks, which left him with hysterical paralysis of the lower limbs. He became worse, and in 1880 was sent to the asylum at Bonneval, suffering from periodical epileptiform fits, and from paraplegia. He was now a quiet, well-mannered boy of seventeen, and the change in him for the worse was as yet merely

* 'The Dual Function of the Double Brain.'

† Fully described in medical detail by Dr. A. T. Myers in *Journal of Mental Science*, 1886.

physical. He had, indeed, forgotten how to read and write, but this was probably to be accounted for by want of practice, for he distinctly remembered his life before entering the reformatory, and was deeply ashamed of it. He was employed at tailoring for two months; then he had a severe attack of hystero-epilepsy, after which he slept for several hours. He awoke from his sleep entirely free from paralysis, and got up, intending to work in the fields, as he had been used to do at the reformatory, where he now believed himself to be. He walked with comparative ease, though somewhat uncertainly, a consequence of muscular atrophy from disease of the limbs. He recognised no one about him, and had entirely gone back to the time before his fright. His disposition was completely changed. From being quiet and tractable, he had become quite the reverse, and he was found out in a theft. In 1881 he escaped from Bonneval, and after a few years, which he spent partly in drifting about from hospital to prison, partly as a private of marines, he was sent to the asylum of Rochefort, having been convicted of a theft, but judged to be of unsound mind. Here he came under the care of Drs. Bourru and Burot, who carefully observed his case, as Dr. Camuset at Bonneval and Dr. Jules Voisin at Bicêtre had already done.

At Rochefort he developed hemiplegia of the right side, with consequent indistinctness and difficulty of speech, notwithstanding which he was extremely impudent and abusive, and ready to expound his theories, which were all adverse to established authority. He could now remember only detached vicious periods of his past life. Contact with metals (metallo-therapy) was tried upon him: silver, lead, zinc, and copper had little or no effect, but when a bar of steel was laid upon his paralyzed arm, the hemiplegia shifted from the right side to the left, which became insensible. Such a physical change is not uncommon, but the coincident mental change was unexpected and startling. Louis V—— had become another creature. The insolent and unmanageable patient was

now gentle, modest, and respectful. His speech was once more distinct, but he now declined to give any opinion on important matters, declaring himself unable to judge of them wisely. His experiences as a marine were absolutely forgotten, and he remembered only the more reputable epochs of his life.

These two contrary conditions, evil and good, were by his physicians called his first and second states, and from them several intermediate and varying states could be produced. His 'fifth state' was especially curious. By being placed in an electric bath, or having a magnet applied to his head, he could for a time be wholly cured of paralysis. He became light and active as a healthy child, and on questioning him it was found that he had indeed gone back to childhood. He was again at the reformatory, and all his life after his fright from the viper was an utter blank. But let him be in any way reminded of that circumstance, and he fell at once into an epileptiform condition, which left him in his 'first' or 'second' state.

Louis V—— is now no longer at Rochefort, and, according to the last account of him, his health and psychical status are both much improved.

The physicians who have had charge of this extraordinary case agree in supposing that the various observed changes point to a dual action of the brain, and the unstable preponderance of one hemisphere. The imperfect speech, and violent, insolent conduct associated with the right hemiplegia, in contrast with the clear speech and self-controlled demeanour which accompanied the left hemiplegia, show the contrasting tendencies (in this case) of the supremacy of the right and left hemispheres respectively.

Such marked effects of brain duality seldom appear spontaneously, except among the insane, idiots, and sufferers from brain disease or delirium. Dr. Ireland gives a case of double personality, which he has witnessed in an idiot boy named Finlay. This lad would talk to

himself, and argue as if two persons were discussing a question. Sometimes he would thrash himself, saying, 'Finlay is a bad boy to-day,' and then would cry out with pain in his own personality. In some cases, where insanity follows upon injury or disease of one-half of the brain, the patient is conscious of the struggle for mastery which is being carried on within him. The organism which remains sound controls the insane impulses of that portion which is damaged, until at last it becomes tired out, and partakes of the common intellectual ruin.

A most remarkable case of double personality is that of Félida X——, which is fully described by Dr. Azam,* Professor in the University of Bordeaux. Félida was born in 1843, of respectable parents. From childhood she showed a melancholy and reserved disposition. She was subject to hemoptysis, and dwelt continually on her bad health. At the age of fourteen and a half her first transformation occurred. After a sudden pain in her head, she fell into a short trance, from which she awoke completely metamorphosed. She was now bright and lively, very loquacious, and even noisy. Her health seemed improved, and she did not complain of any ailment. But after a few hours she again fell into a trance, and awoke to find herself in her first or normal state. Henceforth she passed her life alternately in one or the other of those two conditions. For some time the 'second state' did not occupy more than a tenth part of her existence, but by 1875 the relative duration of the two states, which had been changing by degrees, had become reversed, so that she was nearly always in the second state. In this latter condition her memory of the past is complete, but in her first state all that has occurred in her second is utterly forgotten. Hence have ensued some curious complications; for instance, while in her second state she showed a very decided preference

* 'Hypnotisme, Double Conscience,' etc., Paris, 1887. One of the most interesting histories ever written, Professor Azam being a master of style as well as a scientific observer of the first rank.

for a young man, whom in her first she completely ignored. On one occasion she was attending the funeral of a friend, and while returning home in the carriage she had an access of trance, which lasted only a few minutes, and aroused no remark. She awoke in her first state, without any recollection of why she was in the carriage, or whose funeral she had been following. By questioning, however, she managed to set herself right without betraying her change of personality. In due time Félida married and became the mother of several children, but the alternation of personality went on as before, and assuredly she could have no secrets from her husband, as in her second state she revealed everything she had done in her first, even though she had intended to keep it secret.

Both Louis V—— and Félida X—— proved excellent subjects for hypnotism, and in the case of the former hypnotism produced the same alternation of personality as did metallo-therapy. In this case it seems fair to attribute to its use by Drs. Bourru and Burot some of the credit of his recovery and reformation.

In the cases of Louis V—— and Félida X—— hypnotism seemed to produce still another phase of personality, but Dr. Richard Hodgson describes a very interesting case of double personality in which hypnotism evoked the 'second state.' The subject was an itinerant preacher, named Ansel Bowne, sixty-one years of age, who one morning disappeared mysteriously from his home, and in spite of the efforts of his friends remained undiscovered for two months. He woke up one morning at Norristown, Pennsylvania, to find that he was keeping a small general shop under the name of A. J. Brown. He had been engaged in this occupation for six weeks, and had appeared to his neighbours as a perfectly normal individual. As a matter of fact he had been in a state of somnambulism all the time, and he knew nothing on awaking of what had befallen him since he had fallen into a trance whilst walking in the streets of the town where he had been living. Professor James and Dr. Hodgson hyp-

notized him, and in the hypnotic state he resumed the personality of A. J. Brown, and told his audience what he had been doing during his residence at Norristown and how he got there.*

I have recently (1899) met with a curious case of double personality. The patient is a bank clerk, aged forty, with a record of over twenty years' satisfactory service. He left the bank one Friday after luncheon, and did not return until the following Monday, when he found he had been suspended for absence without leave. He could give no explanation of his conduct beyond that he had found himself late on Saturday night in a strange hotel at Southampton. How he got there he didn't know, but he found in his pocket some postal orders issued at Guildford, so he concluded he had visited that town. I hypnotized him, and he at once became somnambulic. He replied to questions, and gradually gave us a complete history of his doings from the time he left the bank until he 'came to himself' at Southampton. He had gone first to call on a friend in the West End, and then on another friend in the suburbs. He had spent Friday night in a temperance hotel, and had gone to the station in the morning and taken the first train which happened to be going to Guildford. There he alighted and had breakfast. The previous day he had changed a cheque, so he had ten pounds in gold in his purse. This he found heavy, so he exchanged the sovereigns for postal orders. Then he felt he should like some sea-air, and took the train to Southampton, where he formed the plan of taking a coasting steamer to Dublin, a trip he had formerly made with enjoyment. He strolled about Southampton, behaving much as an ordinary visitor, and engaged a room at a hotel. At this hotel he suddenly 'came to himself,' and was astonished to find himself in a strange place. He was just in time to catch the last train to London, where he stayed the night, and thence returned to his anxious family in the country the following morning. His friends

* Proceedings of the Society for Psychical Research, July, 1891.

were naturally somewhat sceptical, and it was perhaps fortunate for him that some of them had heard of double consciousness.

By hypnotism one was able to tap, as it were, the submerged level of consciousness which had prevailed during the thirty-two hours' alteration of personality. It was a period of some excitement whilst we extracted from him sentence by sentence the way he had spent his time, and the question occurred as to what duty would demand if it turned out to be a case of Dr. Jekyll and Mr. Hyde, and our patient confessed while hypnotized to having committed an atrocious crime. But the second personality of a middle-aged bank clerk could hardly be expected to soar to any very great height, or to descend to any great depth, and so it proved. But there did seem to exist in the second personality a peculiar absence of forethought and responsibility, and a tendency to act on the impulse of the moment, so that no definite plans were formed, and there was no compunction felt at the inconvenience caused in the bank or the panic felt at his home.

I have seen two other cases of double personality during the last few years, and the *British Medical Journal* has recently reported a series of cases by Dr. Hyslop.* Such cases are probably more common than was formerly supposed, and now that they are becoming more understood, such patients will be less averse to telling their experiences. They involve a problem of extraordinary psychical interest: our individuality depends upon a continuity of memory and consistency of action, and the upsetting of these conditions introduces an embarrassing break in the chain of cause and effect.

Some of the French experimenters have in the hypnotic state made middle-aged people feel again the sentiments of their childhood, and write, talk and behave as they did when children of six or seven. Miss Goodrich Freer in

* On 'Double Consciousness,' by T. B. Hyslop, M.D., Medical Superintendent of Bethlehem Royal Hospital, etc., *British Medical Journal*, September 23, 1899.

her experiments has shown how she reproduces forgotten memories by crystal-gazing, and Dr. Morton Prince has recently published his experiments in the same field with a highly sensitive, hysterical young lady. In this patient he was able to induce a second and a third personality by hypnotism very different to her ordinary self. Normally Miss X——, as he calls her, is reserved, morbidly conscientious, self-contained, serious, deferential and shy. In her second state (X—— 2) she is sad, serious, and gives the impression of weariness and suffering. X—— 3 is flippant, jovial, free from all physical infirmities, full of fun, reckless, and contemptuous of the normal self, X—— 1, whom she stigmatizes as silly, stupid and dull, and of whom she makes great fun. Nothing seems to amuse her more than the recital of the woes and worries of X—— 1.

For instance, Miss X—— one morning came to Dr. Prince in a very disturbed state of mind. She had lost the money she had set aside for her stay in Boston, and was almost penniless. She was put into the profound state of hypnosis, wherein she developed the personality of X—— 3, and then described how stupid X—— 1 had felt nervous about her money the night before, and had got up from her bed and hidden it under the table-cloth, and X—— 3 seemed greatly amused at the embarrassment caused by this loss of money. Dr. Prince awoke her, and, without telling her anything, asked her to look in a crystal. She did so, and described the scene which presented itself: she saw herself in bed in her room; then she saw herself get up, her eyes being closed, and walk up and down the room, go up to the bureau, take the money from the drawer, and hide it under the table-cloth. This proved to be the correct explanation of the loss, which was thus put right.

To show the conflict of personality: on one occasion as X—— 3 she tore up and threw away a bundle of bank-notes so as to annoy and embarrass X—— 1. In her normal state she knew nothing of this, and thought

she had been robbed. Dr. Prince hypnotized her, and brought back the personality of X—— 3, who confessed the deed with malignant satisfaction the next morning.

I don't know the end of this case. Probably Dr. Prince cured her of the ailments she consulted him for, and by suggestion suppressed the somewhat inconvenient personality of X—— 3.

I once cured in one sitting a nurse of spontaneous somnambulism, to which she had been subject all her life. The curative aim of the physician is occasionally in conflict with the claims of the psychical researcher, and one sometimes feels it a duty in the interest of the patient to put a stop to interesting developments.

I do not mean to imply that 'seers' are always hysterical and in poor health; on the contrary, Miss Freer, who has been already referred to, is a lady of great talent and practical achievements in many directions; and I understand from Professor James and Dr. Hodgson that the well-known Mrs. Piper, whose case they have investigated with such care, is a healthy woman, and appears to be benefited by carefully-conducted psychical experiments. But rash and ignorant experimentation on such subjects is strongly to be deprecated.

These cases throw some light on much which goes by the name of clairvoyance and occultism, and it is, I think, a healthy sign that a physician of Dr. Morton Prince's position should be ready to investigate such phenomena.*

Mr. Myers' theory is that both by hypnotism and crystal-gazing one taps the 'subliminal consciousness,' and thus gets into touch with a far wider field of experience than our everyday consciousness supplies.

I have called the first state of Félida X—— 'normal,' but should it be thus called merely because it happened to be the first? It is incomparably inferior to her second

* 'An Experimental Study of Visions,' by Morton Prince, M.D., Physician for Diseases of the Nervous System, Boston City Hospital, *Brain*, Winter, 1898.

state, which has now almost entirely replaced it. In this second state Félida is frank and cheerful in her manner, an active woman of business, and an excellent mother.* In her now rarely recurring first state — her *état bête* as she herself calls it—she is reserved, gloomy, and selfish. Which of these two is her sane, her truly natural condition? which her abnormal? Such instances lead us to inquire, Can the good effects which in this woman occurred spontaneously be brought about by outward means? The reassuring answer is that they can be, and have been, thus brought about, and in the future will be wrought more frequently and more completely. The newer hypnotism is still a young science, and before the physician and the moral reformer lies a vast field of psychical possibilities still to be explored.

Richet† describes how by hypnotic suggestion he changed an enthusiastic Bonapartist into an equally enthusiastic Republican, who furthermore recognised her conversion. 'Vive Gambetta!' cried this lady. 'A veil seems torn away! How mistaken I have been about him!' The effects of such an experiment as this are of course superficial and transitory, but such incidents point to possible induced moral changes, which may be rendered deep and permanent.

Richet (*op. cit.*, p. 250) and A. Pitres (*Revue de l'Hypnotisme*, December, 1890) suppose that personality depends upon memory of previous events and their relation to one's self, and that this condition is never affected in the lighter grades of hypnosis, and only with comparative rarity in the deeper states of somnambulism. According to Pitres we find alteration of personality taking place in three different ways—by alternation, alienation, and reversion. All these occur under certain circumstances in the waking state, and they may be induced in susceptible subjects by hypnotic suggestion. Thus, Azam

* The changes are chiefly psychical. In both states she suffers from chronic asthma and general delicacy of health.

† 'L'Homme et l'Intelligence': Appendix.

(*op. cit.*, p. 245) mentions the case of an insane patient who always told him of her own symptoms as if they belonged to a friend: 'I wish to consult you about a tumour which she has in her breast, and which causes her great pain,' etc., the person meant being herself. The way in which children speak of themselves in the third person is a matter of common observation. 'Freddy is a good boy, Freddy wants to go to bed,' etc. It is probable that, as memory is extremely limited in young children, their individuality and personality is vague and undeveloped. In insanity it is common enough to meet patients who believe themselves to be other people, generally of historical or present celebrity or importance. In the advanced hypnotic state it is often possible to make the patient believe and act as if he were any person whose name is suggested to him, and he will endeavour to act the character exactly like one under insane delusion. It is this feature of hypnotism which is brought into such requisition by platform professors, and to the ignorant and careless it is a matter of merriment to see a stalwart countryman imagine himself a baby or a schoolgirl, or to see a young girl act the part of a general. For sex presents no bar to the reception of suggestions. The cases of change of personality by alternation cannot be better illustrated than by the foregoing ones of Victor V—— and Félida X——. Examples of alteration of personality by reversion are not uncommon in medical practice. A patient in delirium frequently fancies himself a boy again, and, forgetting everything which has occurred in recent years, will remember and act over again trivial scenes of an apparently long-forgotten childhood. Dr. Pitres (*loc. cit.*) gives an interesting account of a hysterical patient who had frequent attacks of amnesia, during which the events of the preceding few years were absolutely forgotten, so that it was impossible to make her recognise her friends of the time. Not only did she speak and act as she had done in her youth, but it was evident that her mind was working in exactly the same way as it had done

then. Dr. Pitres found he could at any time produce this reversion by making her fix her attention strongly on some event in her past life, and then hypnotizing her while she so thought of it; and he obtained the same result by pressing on certain parts of the body which seemed to act as ideogenic zones. In this case of Albertine M—— she suffered from hemianæsthesia in her normal condition, but if by hypnotic suggestion she was put back to a period prior to the incident of this symptom, *i.e.*, to her childhood, this condition no longer was present. Just as we have seen in the case of Victor V——, *per contra*, the induction of paralytic symptoms brought the patient into the mental condition which went with this symptom. The two cases are most instructive as showing the very close relationship between psychical changes and physical states.

Dr. Auguste Voisin has recently kept several of his patients for long periods of time in a state of altered personality, and there is no doubt but that in effecting moral reformation we do not so much create new personality as bring out traits of character which have either been forgotten or have remained undeveloped.

Liébeault describes the case of a Pole who was under his treatment for epilepsy. The man was very excitable, and had been a soldier in the Polish rebellion. After each attack he became so violent that it took six men to hold him in bed. During his violent struggles he would shout and declaim as though in the heat of a desperate engagement, and even after he had become calm and quiet he would for some minutes believe that he had been fighting in a battle, and would recite the incidents he thought he had witnessed. The vision was always the same. A desperate fight against overwhelming odds, a town in flames, and the whole scene illuminated by a moon of fantastic form.*

The head-master of a boys' school tells me that he is

* 'Thérapeutique Suggestive,' p. 142.

obtaining good results in the suggestive treatment of moral disease and of mental torpor, and some of his pupils declare that when they have been hypnotized their sums 'come easier' to them than usual. Some time since, I was called upon to treat a case of moral perversity —a young girl, who has greatly improved under the influence of suggestion. From being idle and rebellious, she has, so I am told by her teachers, become docile, and has developed a decided aptitude for study. A 'chronic' medical student, in about his tenth year, who consulted me occasionally, assured me that my treatment 'wound up' his intellectual machinery, so that he could work several hours a day after each visit. As this gentleman was only slightly hypnotizable, I do not take much credit to myself for this good effect; but I do claim for hypnotism the results achieved in another case, also that of a medical student. The patient was not only idle, but was addicted to drink and dissipation. At heart, however, he was a good fellow, and was much beloved by his friends. He came to me in despair, and assured me hypnotism was his last chance, and that if it failed he should shoot himself. It succeeded, and he is now in good practice, with an excellent wife, and every prospect of a life of happiness and usefulness.

Dr. Hugh Wingfield relates the effect of hypnotism on one of his Cambridge subjects. The young man was clever and well-meaning, but an inveterate idler, and could not settle to work. In a state of profound hypnosis Dr. Wingfield 'suggested' that he should retire to his rooms every evening after dinner and settle down to steady work until midnight, that he should 'sport his oak' and deny himself to his friends, and that he should pass his forthcoming examination. The suggestions succeeded perfectly, and in six weeks the patient passed a good examination, much to his own delight and to the surprise of his friends.

Liébeault tells of a school-boy who was hypnotized as an encouragement to his younger brother, who was the

real patient. He proved such a good subject that it seemed a pity to waste the opportunity, and so the doctor 'suggested' great industry and hard work, so that he might rise to the top of his class. The boy was intelligent but idle, and the suggestion had such effect that for three weeks he worked so hard that he did occupy the top of his class instead of his usual place at the bottom. But he gradually deteriorated, so his mother wanted to take him to Liébeault again. The boy, however, absolutely refused to go, for he said he didn't like that doctor, because what he did made him work too hard.

On the other hand, Vincent relates how he suggested to a history student that the battle of Hastings was fought in 1067; for several days, if asked for the date, he gave that, and stuck to it. And there is the story of a French accountant, whose books all went wrong because he was told, when profoundly hypnotized, that two and three made six. Such an upsetting of one's experience and knowledge would not last long without repetition of the suggestion, for the mental pendulum would swing back to its normal position, as in the case of Mrs. S—— and the cat (p. 70).

I have been asked to treat several children who were unsatisfactory. In one case a boy of fourteen wrote to me from a public school, asking me to hypnotize him to enable him to overcome certain bad habits and the intellectual lassitude which he supposed to be their result. The boy proved an excellent subject, and responded perfectly to the suggestions I made. He worked so well that he took a good scholarship, and afterwards became a high wrangler at Cambridge. Medical men and parents often notice that boys about the age of puberty become idle and unsatisfactory, and such cases require very careful management, as the boy's future is at stake. Hypnotic suggestion in good hands is very useful in tiding over this critical period.

It should be clearly understood that the use of hypnotic suggestion as an educational influence should be carefully

restricted, and never allowed to interfere with the healthy development of individual character. It should be reserved for cases where there is inherited or acquired vicious tendency, and should even then be resorted to only when other means have been fairly tried and found ineffectual. We know that in some young persons there is a complete breakdown of the moral self, while in some others it seems entirely absent, and it is for children of this debased or deteriorated type—such children as abound in our reformatories—that this moral treatment will prove most useful. I would especially mention its power to cure the inherited craving for alcohol, which so frequently appears in the neuropathic children of drunken parents. In an article I contributed to the *Medical Annual* for 1898 I laid great stress on the value of hypnotic suggestion as a *corrector of bad heredity*, and of all the uses of hypnotism I believe this to be the greatest.

Bérillon, as Government Medical Inspector of Public Asylums in France, has great facilities for studying abnormal children, and he has employed hypnotic suggestion largely in correcting vicious tendencies. He has made a special study of degeneration in children, and among the signs of this condition he reckons nail-biting (*onychophagie*), nocturnal enuresis, masturbation, and excessive pusillanimity. These conditions are very amenable to hypnotic treatment.

Many persons have objected to the educational use of hypnotic suggestion, on the ground that it is a tampering with the 'free-will' of those influenced. It is true enough that the will should not be *weakened*, but who would say that it should not be interfered with? Is it not a fact that all education and all moral training are an interference with free-will? The child who delights in school-work needs no coercion to application. The child—if such a one there be—who has no moral faults whatever, requires no exhortations to unselfishness, truthfulness, and other good qualities. But most children prefer play to work. Some will tell a lie to escape punishment; all, so it seems,

have a variety of failings and bad habits, so that reformative and preventive means must be used to train them to industry, truth-telling, and general excellence of conduct. It is, as I have said, only when those ordinary means have failed that hypnotic suggestion should be employed, and then it should work on the same lines as all judicious education: the child should not be made to obey like a slave or an automaton, but should be guided by suggestion, as by a wise teacher, to practise *auto*-suggestion, and thus, by his own will-power, to aid in the overcoming of bad habits and the acquiring of good ones.

Some enthusiastic advocates of hypnotism argue that as nearly all normal children are readily hypnotized; as it is much more easy to hypnotize patients who have been operated on previously; and as conditions are very likely to arise in after-life in which the induction of hypnosis would be of advantage for combating pain, inducing sleep or anæsthesia, or correcting evil habits; it is very desirable to hypnotize every child, so as to be able to invoke the agent when required.

I confess to have no sympathy with such a contention, but, on the contrary, incline to the opinion of a medical friend who says he would rather have his child naturally naughty than hypnotically good—if by 'naturally' he means the ordinary faults and shortcomings of free, happy and healthy childhood. If he were the parent of such a child as is described on p. 320, I dare say this gentleman would modify his opinion, and be glad to employ the only remedy which, as far as I know, is available in such cases.

When the mental powers are deficient by reason of faulty brain structure, hypnotism cannot, of course, do much. No one professes to create new gray matter by hypnotic suggestion. Still, the records of our asylums show that even when the brain is almost rudimentary, educational influence may be successful in producing decent and orderly habits. But in complete idiotcy it is almost impossible to hypnotize, and suggestions are powerless through want of a *point d'appui*.

At the Nancy Congress Dr. Liébeault and others gave instances of dull, idle, and unmanageable children who by suggestion (combined in some cases with judicious home influence) were made models of industry and good behaviour. Schoolboys who had habitually kept at the bottom of their form were by this treatment so incited to work that they soon occupied a place at the other end. Another child, seven years of age, so obtuse as to be almost an idiot, was so benefited by suggestion, that in three months he could read, write, and understand the four rules of arithmetic.

What other remedy but hypnotism can be suggested in such a case as the following, which I treated in 1895? A lady interested in reformatory work brought me a girl of fifteen to see if hypnotism could help her. She was a workhouse child of degenerate type, but not imbecile. She had been placed in two different situations as servant, and in each case had been sent away for theft. At the home she was put to laundry work, and there being nothing else to steal, she used to steal the soap and the other girls' bread-and-butter. These she hid away, but made no use of.

She proved a good hypnotic subject, and I suggested that in future she should know she was doing wrong when she stole, and should be able to refrain; that she should work industriously, and be honest, truthful and attentive. In all these qualities she was deficient, but after being hypnotized a few times a great improvement was perceptible, and she was sent to a third situation. She was reported (1899) to be still in that situation, and to be giving complete satisfaction. Hypnotism probably saved the girl from a life of misery and crime, for kleptomania is not recognised among the poor.

Dr. Hack Tuke, speaking of 'moral insanity' (*Journal of Mental Science*, 1885), well puts it when he says that in cases of this description, where, perhaps, the disposition and actions of one member of a family will by their perversity bring untold suffering on his relations, there is

undue development of the lower or automatic functions, whilst the higher centres are defective, and that it should be our object to correct this disproportion by suppressing some functions and developing others. If (he goes on to say) the horses drawing a coach run away in consequence of the driver being drunk, it is not the horses we should blame for the accident, but the incapable driver who is no longer able to hold the reins. We know that badness may proceed from two causes, which Dr. Tuke calls moral resolution—positively bad, and moral irresolution—negatively bad. It is probable that in either case, if the offender were caught young, hypnotic suggestion would prove a valuable adjunct to other reformative agencies.

In course of time the new personality, induced by suggestion and encouraged by religious ministration and teaching, will displace the old, and a complete moral revolution will be the result.

In those cases a state of double consciousness, such as one sometimes sees in natural somnambulism, was probably induced. A subject of this kind may live two alternate lives, one good, the other evil; and in one of these lives she will be unconscious of her actions in the other (Forbes Winslow, *op. cit.*, p. 420). In some instances both of these utterly different lines of conduct will appear so rational that it is difficult to decide which is natural to the subject.*

One is frequently asked whether the cures worked by suggestion are of a permanent character. To this I reply, they are as permanent as cures effected by any other means. Relapses occur in many diseases, no matter what treatment has been employed—sometimes through some carelessness on the part of the patient or of those who have charge of him. A person who is cured of rheumatism to-day, may to-morrow get fresh cold and develop a new attack, or other symptoms. But with proper attention, and the customary precautions as regards diet, rest, tem-

* The story of 'Dr. Jekyll and Mr. Hyde' might be founded on one of these cases.

perature, etc., the success of this treatment is not transitory. The improvement effected by its means is often so marked and so rapid that patients are tempted to discontinue its use, and return to their ordinary habits before the cure is perfected and the habit of disease broken, forgetting that when a diseased condition has existed for some time it probably has taken firm hold on the system, and is not to be dispelled in a day. Sudden cures are apt to be fallacious, as are such cures by other modes of treatment; and though brilliant results are sometimes attained, they can never be counted upon, and there should be no disappointment when improvement is a little delayed.

I have certainly found two statements commonly made about the treatment to be fallacious. The first, that the effects are temporary, and that amelioration of the symptoms is followed by speedy relapse and a deeper sinking into the slough; and the second, that if a relapse occurs, the patient will not a second time be benefited by the treatment. I have treated patients for various ailments who were cured two years ago and have had no relapse, and others who, from the nature of their disease, have experienced relapses, have almost invariably been relieved by subsequent hypnotization, and more speedily than on the first occasion.

On the very threshold a difficulty may occur: the patient will perhaps appear insusceptible. This need not cause discouragement, for in many cases the hypnotic influence is not felt until after three or more sittings. Comparatively few persons remain insusceptible* to it;

* See tables, p. 58. An apparent trifle may cause one operator to fail where another will succeed at once. I know a very able foreign physician, who completely failed to influence two English patients, because he smelt of garlic, and so called up disturbing emotions in their minds. I was once unsuccessful with a gentleman, who afterwards told me the reason of my failure. He imagined, as many do, that it is essential for the operator to possess great strength both of mind and body. When I touched his eyes to close them, he observed a slight tremor in my hand, and attributed this to a physical or mental weakness, which, he argued, must prevent my influencing him—a stranger, and a strong man of high intellectual capacity. The idea

and when once it is established, the hypnotic state is afterwards more easily induced, and tends also to become more intense, though this does not necessarily follow.

It is very difficult to eradicate a deeply-rooted popular belief, and it is not very easy for a practitioner of the suggestive system to avoid being called a magnetizer, since artificially induced sleep is the common preliminary of the treatment. But, as I have already stated, Dr. Liébeault and his disciples absolutely reject the fanciful theories regarding animal magnetism which were held fifty years ago. They contend that no unusual gifts are needed to practise the system, and that the chief requisite is confidence. (The footnote on p. 109 shows how want of confidence may be detected by the patient, and how the very suspicion of it will cause failure.) With wider experience comes increased confidence in one's self and in the system, followed naturally by increased success.

But 'majus remedium majus venenum' is a true saying, and it would be an exception to all rule if such a powerful remedy as suggestion were not liable to abuse. When dynamite was discovered, no one denied that the lawless and desperate would, if possible, turn it to bad account, yet it was not tabooed for this reason, but its manufacture and distribution have been surrounded by precautions and restrictions, and it is allowed to occupy its proper place in applied science in the hands of miners and engineers. It is interesting to read in contemporary records the controversy which raged round the introduction of chloroform into medical practice fifty years ago. All manner of evils, physical, religious and moral, were foretold as certain to follow man's temerity in interfering

called up a resistance, which rendered him insusceptible. Subsequently, when I had explained to him that my personal attributes were, in this matter, of no consequence whatever, he easily fell into a profound hypnotic sleep. There is, however, a proportion of sane persons—perhaps 10 per cent.—who are to all intents and purposes unhypnotizable. This insusceptibility seems to depend upon idiosyncrasy, and is neither a sign of commanding intelligence nor the reverse.

with the laws of Nature; but Sir James Simpson was a doughty champion, and was not prevented from making public his grand discovery because nervous people were afraid it might be employed for evil purposes; nor is its use forbidden, though every year a certain percentage of crimes and outrages are committed by its aid.* Poisoning by arsenic, corrosive sublimate, and digitalis sometimes occur, and yet these drugs occupy a prominent place in the pharmacopœia; for it is found that, although those powerful agents are sometimes used to inflict harm, the evil caused by their illegitimate employment is so outweighed by their usefulness that no one would think of suppressing them. So with hypnotism. Its power for good is undoubted; it fills a place that nothing else can fill so adequately, and used with proper precaution and under necessary restrictions, it is perfectly safe.

Dr. Sémal, in the discussion on hypnotism in the Belgian Academy of Medicine (June 30, 1888), having condemned the prostitution of the system by travelling *prestidigitateurs* and charlatans, spoke strongly in favour of having it included in the medical curriculum of the Universities, as being the only legitimate means of making it known. 'This course,' he said, 'would prevent its being used empirically and stupidly, and would keep it as a powerful therapeutic agent in the hands of the medical profession so long as the art of healing is practised.'

The exploitation of hypnotism as an exhibition at public entertainments has already been prohibited by law in Switzerland, Holland, and other countries, and when the true position of this treatment is understood among us, the

* I am informed by credible witnesses, who were living in Edinburgh at the time, that Professor Simpson used to invite his friends to his house to experiment with the new agent, and it was quite common for several of the guests to narcotize themselves that they might compare experiences. This affords another analogy between the introduction of hypnotism and that of chloroform, and we may hope that as chloroform soon got beyond the popular and experimental stage, so may hypnotism be freed from its platform and drawing-room exponents.

same restrictions will probably be enforced in England.* 'The performance of experiments in public,' write Binet and Féré (*op. cit.*), 'should be condemned, just as we condemn public dissection of the dead body, and vivisection in public. It is certain that there are still graver objections to hypnotic exhibitions, since they are liable to produce nervous affections even in those who do not propose to be the subjects of experiment.' Such experiments, I maintain, are always useless and often cruel, besides being an offence against the dignity of humanity. The contortions and exclamations of a patient under chloroform are often interesting, and might by some persons be thought amusing, but we should hardly choose to excite them for the gratification of idle curiosity or the entertainment of the multitude.

By all means let people be made aware of the existence and nature of an influence to which most of us are susceptible, and some to a dangerous degree: for to be forewarned is to be forearmed, and we shall not have foolish persons playing with such an edged tool if they know how serious may be the consequences of their trifling. A paragraph which lately went the round of the papers shows how ignorance may lead to awkward results. A couple of young men went to a café after attending a 'magnetic' performance, and one of them, full of what he had seen, proposed 'magnetizing' the barmaid. She consented, and he imitated the 'passes' made by the lecturer. Very soon the subject fell into a hypnotic trance, from which neither of the young men could arouse her. Like Ali Baba's brother, they had got into forbidden regions, and did not know the password which should let them out. The police were sent for, the young woman was taken to the hospital, where after a time she awoke, and the operator was arrested and locked up.

The following case has recently come under my own

* One of the objects of the International Congress of physicians practising hypnotism, which was held in Paris in 1889, was to pass a strong resolution dealing with this question, and calling upon Governments to render public exhibitions of hypnotism illegal.

notice, for my advice was sought by the much-perplexed experimenter:

A young gentleman, after a few lessons from a public magnetizer, went to stay in a country house where, among other guests, was a young lady of well-marked hysterical temperament. To show off his recently-acquired knowledge, and to afford a little amusement, he undertook to hypnotize this girl, and after a few minutes' employment of the method known as *fascination*, the subject fell into a profound trance. He had some difficulty in arousing her, and ever since she has had frequently recurring fits of cataleptic trance, which are always ushered in by an outburst of screaming, in which she cries: 'He is doing it now!' She is under the impression that the young man is constantly exercising a power over her, though he is hundreds of miles away, and her nervous system is reduced to a state which causes serious alarm to her family. That her idea is absurd, and that such action at a distance is impossible, renders the matter none the less painful for the young lady and her family, or less awkward for the rash experimenter. Such an occurrence naturally fills people's minds with dislike and distrust for hypnotism, for they confuse a wanton and clumsily-conducted experiment with a medical treatment of which hypnotism forms only a preliminary step.*

On the occasion of an academic discussion on hypnotism at the annual meeting of the British Medical Association, at Birmingham, in 1890, I read extracts from letters I had received from the best-known physicians practising hypnotism at home and abroad. Bernheim, Moll, Forell, Van Eeden, Milne Bramwell, and others, all wrote that they

* A story told by the late Professor Christison of Edinburgh bears on this point. He one day mesmerized a highly-nervous lady, and when she awoke he told her that the following day, at noon, he would repeat the operation from a distance. At that hour the Professor was lecturing, and had quite forgotten the occurrence; nevertheless, the lady, in spite of all her husband could do to prevent it, fell into a profound trance, and said she felt she was being mesmerized. Expectant attention and auto-suggestion produced the effect, and such is found to be the explanation of most of the stories which are foisted upon a credulous public.

had never seen any injurious effects follow the use of hypnotism by trustworthy hands. Dr. Liébeault told me that in his thirty years' experience he had had no bad results, and referred me to an article he had recently published, entitled 'Confession d'un Médecin Hypnotiseur,'* in which he has set forth the little mishaps which have happened from time to time in his clinique.

I was extremely glad to get this mass of testimony, as it disposed of an idea, not confined only to the uneducated, that medical hypnotism may induce epilepsy, hysteria, chorea, etc. Dr. A. T. Myers also informs me that the subjects he has seen hypnotized many scores of times for the Society for Psychical Research, over long periods of time, are none the worse for their experience. Dr. Liébeault is undoubtedly perfectly correct when he states that where any evil result has followed the treatment, it has been due to want of skill or judgment on the part of the operator. I am convinced that hypnotism is an agent requiring careful handling in many cases; this was brought home to a medical friend of mine, whose experience is worth recording. He was attending a lady suffering from bronchitis complicated with asthma and a weak and fatty heart. He thought to quiet her spasmodic attacks by suggestion, and he induced a state of profound hypnosis with great facility. He continued to suggest easier and quieter breathing, and was pleased to see how the patient responded and how respiration became more and more tranquil. He had not hypnotized many people, and looked upon the process as being quite unattended with risk, until the breathing, having become more and more feeble, suddenly stopped altogether, and the heart-beat became imperceptible. My friend feared the patient would have died—the first victim of hypnotic suggestion—and was intensely relieved when the spasmodic breathing was again heard. As far as I know, no record exists of its having proved fatal. Heidenhain refers to experiments of this kind as being distinctly dangerous, and states

* *Op. cit.*, p. 308.

how he nearly stopped the action of his brother's heart by continued suggestion.

But while contending that the risks of hypnotism in proper hands are infinitesimal, we are strongly impressed with the belief that its use by the ignorant or ill-disposed is fraught with most serious risk to health. Dr. M. J. Nolan relates, in the *Journal of Mental Science* (January, 1891), a case of stuporose insanity which he believes was due to the ignorant employment of hypnotism. The patient was a drunken and dissipated soldier, broken in health by his excesses, and he was hypnotized by a travelling 'professor.' Dr. Van Eeden (*loc. cit.*) records a case of hystero-epilepsy brought on in the same way, and Charcot (*Revue de l'Hypnotisme*, July, 1889) contributes notes of a case in which a woman, after being frequently hypnotized by a magnetizer at a fair, became aphasic for several months, and suffered in health in other ways. Dr. Giles de la Tourette read a paper dealing with this subject before the Paris Society of Legal Medicine, in December, 1888 (*Revue de l'Hypnotisme*, January, 1889), and demonstrated how the passage of magnetizers through the towns of France had been followed by serious epidemics of hysteria and other nervous troubles.* He adds: 'Our country (France) has become the refuge of all the magnetizers, and their advertisements cover the walls of Paris.' Such a complaint can no longer be made, for public performances are now forbidden by the municipality. England is now almost the last refuge of the expatriated magnetizers.

Sir F. Cruise† mentions a case in which 'an attack of brain fever followed the induction of hypnosis by an ignorant and irresponsible operator, and deduces from this and other cases the argument that 'it is highly improper and possibly dangerous for anyone who is not an educated physician, and familiar with the practice, to

* 'Dangers de l'Hypnotisme et interdiction des représentations théatrales.' *Ann. d'Hygiène*, vol. xxi. Paris, 1889.

† *Dublin Journal of Medical Science*, May, 1891.

attempt hypnotism, and that it should never be induced without due reason, precaution and design.'

Dr. Déjerine, Professeur Agrégé of the Faculty of Medicine in Paris, is convinced that the continual making of injurious and absurd suggestions is fraught with evil consequences to the subject, and especially so if the hallucinations are allowed to persist over considerable periods of time. He says the time may arrive when the operator may find himself unable to remove the morbid symptoms he has called into being (*Revue de l'Hypnotisme*, January, 1891). But he adds that he has never seen hypnotism produce any bad effects when it has been properly used.

Dr. Julius Solow* records a case where an amateur hypnotist hypnotized a friend by making him look fixedly at a diamond ring. The subject had severe convulsions and lost the power of speech. Subsequently, looking at any bright object caused him to become violently excited. Commenting on this case, the *British Medical Journal* says (March 28, 1891):

'It should be a warning to amateur hypnotizers and to the foolish people who allow themselves to be played upon by these dangerous showmen. . . . It ought to be understood that hypnotism recklessly played with is capable of doing very serious mischief, and it is the duty of the medical profession in every town to warn the public of the serious risks which are being run.'

The case of Ilma S——, so fully described by Kraft-Ebing,† is frequently quoted as an example of the dangers of hypnotism, and it gives us some idea of what must be the mental condition of the unfortunate persons who are being constantly hypnotized by professional showmen.

Several Italian observers have recorded cases of grave mental troubles following the abuse of hypnotism by public showmen and others. Fiegerio describes a case where the subject, a young woman, after being experimented on by Donato, became affected with spontaneous

* *New York Medical Journal*, March 14, 1891.
† Quoted in *Brain*, April, 1891.

somnambulism, accompanied by impulsive tendencies to strike and destroy (*American Journal of Insanity*, April, 1891).

If a patient should take it into her head to imagine that one was having an undue personal influence over her, as in the case referred to on p. 113, the course to adopt is plain. The physician should decline to operate again, and if the idea persists, he should obtain the assistance of a colleague, whom he should get to hypnotize the patient for him, and to suggest to her the disappearance of the delusion. I have found it necessary to act thus in one case, and the plan was completely successful. The patient, a highly hysterical lady of a certain age, and unmarried, developed a craving for hypnotism in much the same way as she might have for alcohol or morphia.*

There is another reason for the careful regulation of the use of hypnotism, which should appeal to all those who have the progress of science at heart. The process of hypnotizing an ordinary subject is so simple, that it seems absurd to talk of teaching it to a person of ordinary intelligence and liberal education; to see it done a few times is to be able to do it one's self. Of course, this is the least part of the treatment, and, in fact, it bears the

* Every form of treatment is liable to abuse. I have seen two striking examples of this in Weir-Mitchell cases. The rest and frequent feeding proved so agreeable to the patients that they continued this part of the treatment when they returned to their homes.

The first of these patients was a middle-aged clergyman, who became neurasthenic after an attack of influenza. After he left the nursing-home, he made his wife continue to feed him every four hours, and used to lie in bed all the time, except for a few hours on Sunday, when he got up and conducted service in his church. He came to me for hypnotic treatment weighing 20 stone, and in a curious apathetic state. I succeeded in stirring him up and making him change his habits. He had been an extremely active and zealous missionary clergyman, so one had good material at bottom to work upon. The other case was that of a lady, who, when dismissed from the nursing-home, straightway took to her bed, and got her maid to feed her every two hours. She added excessive drinking to overfeeding, and, as we couldn't get her to change her mode of life, she soon died of cirrhosis of the liver and fatty heart.

Both these patients discontinued one essential detail of Weir-Mitchell's treatment—the massage, which renders it possible for the system to assimilate the large amount of food consumed.

same relation to the Nancy method as the administration of chloroform does to a subsequent surgical operation. The practice of hypnotic suggestion is surrounded by pitfalls which only the operator with a medical training can avoid, and the results of the treatment are only of scientific value if they have been checked by investigators accustomed to gauge the value of evidence. At the present time, when the treatment is, we may say, in its infancy, we want every fact scientifically investigated, and therefore it is of immense importance to restrict the field of hypnotism to trained medical workers.* If Dr. Elliotson, a physician of rare ability, and a man of unimpeachable probity, had acted with the discretion shown by Bernheim and other foreign physicians, he would probably have arrived at the truth which it required another generation to extract from a mass of superincumbent rubbish.

There is another danger from the ignorant use of hypnotism as a remedial agent. I cannot agree with some writers who seem to contend that pain must not be interfered with, as it is a part of Nature's recuperative process,† but it is often a danger-signal which should not be neglected. Covering the signal does not do away with the danger it denotes. I have heard a patient suffering from gastric ulcer told by an ignorant magnetizer that she was to go home and eat a beefsteak, and a man with mitral disease directed to run up to the top of a high house. So great is the power of suggestion, that in both these cases the order was obeyed, and the symptoms were masked for a time.

Some persons, especially some young women, are so susceptible, that one has only to get their consent and to bid them go to sleep to induce a condition of profound somnambulism. In such cases 'expectant attention'

* I allude, of course, to medical hypnotism, with which I am chiefly interested. The scientific value of work done by such trained observers as Messrs. Gurney and Myers has been already referred to.

† *Vide* article by Dr. Sinclair Thomson in the *Westminster Review*, December, 1890.

alone seems sufficient, and it is matter for surprise that we do not find more people falling into spontaneous somnambulism, as the condition is so easily induced.

It is these subjects of unstable cerebral equilibrium who are most liable to danger from the abuse of hypnotism, and it is these, consequently, that we should especially seek to protect. I need hardly say that the use of hypnotism towards the accomplishment of a crime or misdemeanour should be regarded as a serious aggravation of the offence.

Charcot in France, Ladame in Switzerland, and Sémal in Belgium, have done much to stop the public exhibition of hypnotism in those countries, by demonstrating the physical and mental evils which have befallen the subjects of such performances. Those who witnessed a so-called entertainment of this kind given in London some years since must remember how fatigued and languid, or excited and hysterical, were many of the subjects. The aim of a public entertainer is to excite wonder or mirth in the minds of his audience, and so long as he can evoke a sufficiently startling note, he cares little, even if he fully understands, that the instrument he plays upon is the delicate organism of the higher brain centres.*

There has been a great deal of correspondence in the daily press about hypnotism and suggestion, and one writer in an evening paper recently complained that after being hypnotized she felt for some time a disagreeable sensation, as of being 'drawn to the operator.' I believe

* Apprehension of danger rests very frequently upon the misconception that loss of volition and amnesia are ordinary accompaniments of medical hypnotism. Such an idea arises from witnessing public performances, and it is difficult to eradicate. The physician who employs hypnotism as a remedial agent neither seeks to obtain somnambulism—in which state alone the patients' memory and will-power are seriously affected—nor, as a matter of fact, does it occur, except in a small proportion of cases. The condition ordinarily attained, and here I can speak from personal experience, is one of gentle lethargy, very similar in character to that agreeable state between sleeping and waking which most of us experience when, after being called in the morning, we give ourselves five minutes' grace before getting up.

that such a sensation, unless suggested during hypnosis by the operator, could only be the result of hysterical imagination, and I have never seen anything of the kind in my practice. Such a statement, however, emphasizes the importance of the rule, that hypnotism should be practised only in the presence of witnesses, and that the patient should be thoroughly awakened before leaving the consulting-room. The best guarantee against the abuse of hypnotism will be its recognition as a branch of medical treatment, to be used by medical men with the same caution as anæsthetics and poisons in general.

The practitioner who uses hypnotism should do so with the same precautions which he adopts in administering an anæsthetic. Chief among these are obtaining the formal consent of the patient, and, when expedient, of his friends, and never operating save in the presence of at least one witness. Thus he will guard himself and his patient from all possible imputation of wrong-doing or abuse of power. I need hardly add that a patient desiring hypnotic treatment will, if commonly prudent, use discrimination in choosing a physician, and will avoid placing himself under the influence of one not known to him, at least by reputation.

The dangers of hypnotism are, I believe, exaggerated. The stories told of persons obtaining undue influence over others by its means are mostly fables, which experience shows to be impossible. Professor Bernheim asserts, and is borne out by other observers, that no one can be hypnotized against his wish, and that, in fact, it is his own will which sends him to sleep. Nevertheless, there is no doubt that after a time the oncoming of sleep is less under the patient's control, and when, as we see sometimes at Nancy, a person is continually being hypnotized by the same operator, the hypnotic state can be reproduced with surprising readiness. I believe that in certain hysterical cases there arises a craving for this, as there might for any other sedative; but such a craving has little chance of being encouraged if the suggestive practice is confined

to its proper sphere. A physician does not go on prescribing narcotic drugs because a patient has a craving for them, but, on the contrary, forbids their use when they cease to be beneficial.

The physician practising suggestion may protect his oversensitive patients from the dangers of being hypnotized by a stranger. He has only to impress upon them, while they are in the hypnotic state, that no one can produce any such effect upon them without their free will and formal consent. The most practised operator would try his art in vain upon one so protected, as Drs. Liébeault and Bernheim have repeatedly proved,* and as I myself

* These physicians were in the habit of hypnotizing an hysterical patient, who used to fall into somnambulism as easily in the hands of one as in those of the other. On one occasion, while she was in this state, Dr. Bernheim told her that she was not to be influenced by Dr. Liébeault. She awoke quite oblivious of this suggestion having been made, and soon afterwards went to Dr. Liébeault, who was ignorant of what had taken place, and asked him to hypnotize her as usual. To the surprise of both patient and doctor, all his attempts to do so were futile, and it was only on communicating the fact to Dr. Bernheim that his colleague found its explanation.

This is so important a point that I asked Dr. Outterson Wood (Secretary of the British Medical Association Committee on Hypnotism) to put it to the test, and he kindly consented. Mrs. M——, who is frequently referred to in these pages, was the subject. The first occasion was in November, 1890. I had not hypnotized Mrs. M—— for several weeks, and had made no suggestions in reference to her not being hypnotized by anyone else for at least six months I told her that Dr. Outterson Wood wished to hypnotize her, and left her alone with him. When I returned in half an hour, I found her asleep, and Dr. Wood informed me he had succeeded in hypnotizing her after trying the method of fascination for about twenty minutes. He was obliged to leave the house to keep an appointment, and I then found Mrs. M—— would not reply to my questions, and was apparently in a deep trance, and only *en rapport* with Dr. Wood. Adopting Liégeois's plan, I said in a loud voice to a patient standing by, 'Mrs. M—— is fast asleep now, but she will awake in exactly five minutes.' Though apparently unconscious, her ears evidently took in the suggestion, and her mind acted upon it, for she awoke to the moment.

This experience affords a hint as to the course to adopt if called in to a case of trance suspected to be of hypnotic origin. Though the subject seemed absolutely unconscious, and would doubtless have proved anæsthetic to violent stimuli, her brain responded to the stimulus of an indirect suggestion.

We repeated the experiment in June, 1891, but I previously hypnotized her daily for three days, and each time suggested that on no account was she to allow herself to be hypnotized by anyone else, and I got her to promise that this should be so. I again left Dr. Wood

have seen. I always safeguard my more susceptible patients against the danger of being hypnotized against their will by telling them that no one will be able to influence them without their previous consent in writing, and I find this plan acts admirably. In fact, the more susceptible the patient, the greater the effect of this deterrent suggestion, so that I have seen practised operators experiment on such subjects without producing any other effect but restlessness and discomfort. In one case, that of a young girl, who is one of my best subjects, I asked her to allow a lady doctor to hypnotize her, and she gave her consent. Nevertheless, she proved quite insusceptible to the lady's persevering attempts. The patient told me afterwards that she had a very strong objection to being hypnotized by a stranger, and that her consent was only assumed.

Disregard of this simple precaution was to my mind one of the most regrettable features of the late Dr. Luys's clinique. Some of the young women there seemed to be at the mercy of anyone who cared to exert an influence over them.

One is sometimes asked, even by medical men, if the fact of having hypnotized a patient does not enable the

---

with her alone, and told her that he wished to hypnotize her. She did not remember having promised that she would not allow herself to be hypnotized, but she expressed disinclination for the operation. However, a little persuasion made her give her consent, and Dr. Wood again sought to influence her by fascination. When I returned I found her very hysterical, and complaining of feeling faint and ill; but she was not hypnotized, though the process had lasted twenty minutes. I hypnotized her at once by stroking the forehead, and the disturbance of breathing and circulation disappeared in a few moments. She awoke feeling quite herself, but told me she would never allow anyone else to try to hypnotize her, as the suffering she experienced was acute, and she would have given anything to have escaped it by closing her eyes and going to sleep, but felt constrained to keep awake. This patient had been hypnotized by me the first time I tried in less than two minutes, and there is no doubt but that any competent operator would have been equally successful. Her yielding to Dr. Wood's first attempt only after a long struggle, and her not yielding at all the second time, seems to offer conclusive evidence that so far from previous hypnotization necessarily increasing a person's subsequent susceptibility, it may be used so as to very greatly diminish it.

practitioner to exercise more than the proper amount of influence over him in future. Nothing of this kind is at all likely to happen, and the doctor who uses hypnotism will find neither more nor less gratitude from his patients than if he employed more material remedies. The importation of hypnotism into a recent case, however, shows the danger the medical attendant may incur by running counter to popular prejudice, and how necessary it is for him to safeguard himself (*vide* p. 368).

I may fitly bring this chapter to a close with a quotation from Professor Bernheim's oft-referred-to work: 'It is the duty of the physician to select what is useful in suggestion, and to apply it for the benefit of his patients. When, in the presence of sickness, I think that therapeutic suggestion has a chance of success, I should consider myself to blame as a physician if I did not propose it to my patient, and if I did not even make a point of getting his consent to its employment' (*op. cit.*, p. 580).

CHAPTER VI

Some Points in the Physiology and Psychology of Hypnotism.—Authorities and their Theories.—Expectant Attention, Suggestion, and Inhibition.—Induction of Functional Aphasia, and what it teaches.—Exaggeration or Suppression of certain Senses and Functions in the Hypnotic State.—Automatism in Hypnotism and in the Pathological State.—Amnesia.—Hypnotism compared with the Action of Poisons.—The Double Brain: its Single Action in Health and possible Dual Action in Disease and in the Hypnotic State.—Cases illustrating this.—The Induction of Automatism without Hypnotism.

THE study of hypnotism will doubtless do much to advance our knowledge of the higher brain functions, and it is well to bear in mind that, as the phenomena depend upon an induced psychical condition, they may not be explainable by any physiological method which we at present possess. Charcot, Richet, Bernheim, Heidenhain, Hack Tuke, Ferrier, Hughlings Jackson, and others, have, however, done most useful work by building up a working hypothesis, which serves as a standpoint for future investigators.

Expectant attention, suggestion, and inhibition are the processes which afford an explanation of the commonest phenomena.

Expectant attention seems to be a necessary psychical preparation, for an ordinary person may gaze at an object for an indefinite time without producing hypnosis, unless he expects such a result to ensue. Were this not so, spontaneous somnambulism would be of very common occurrence.

Brown-Séquard and other neurologists show that when one cerebral centre or function is used to excess, the

others become, for the time being, paralyzed or inhibited; and Dr. Maudsley says ('The Pathology of the Mind,' p. 58) that two nerve centres of mental function cannot be in equally conscious function at the same time. Continuous stimulation of one centre implies diminished activity of those surrounding it—including those of higher cerebration: volition, attention, co-ordination of ideas, and memory—and causes their temporary inhibition. This is seen in everyday life. When reading an interesting book, we greatly exert our intellectual and emotional faculties, and consequently impressions on other senses are not registered or noticed. A noise in the street is unheard by us; a coal may fall on the hearthrug, and we neither see the accident nor are affected by the smell of burning wool; even bodily pain and mental suffering may be forgotten or benumbed while the attention is thus absorbed. Everyone knows how gentle friction of a skin surface, in neuralgia or headache, will often act in the same way, by overstimulating one sensory centre, and rendering inactive that which registers the pain.

Heidenhain attributes the hypnotic state to monotonous gentle stimulation of a sense, causing inhibition of the cortical cells, with consequent suspension of the higher cerebral functions. A monotonous sound or scene will thus induce drowsiness or sleep, and a sudden intense stimulation, such as a sudden noise or flash of light, will cause an awakening. This is seen at magnetic séances, where the sleepers are commonly aroused by the sound of a gong.

Let us consider what happens when a person is profoundly hypnotized for the first time by fixation of the eyes upon a brilliant object. As his attention is exclusively directed to one sensory impression, he becomes more and more withdrawn from other conditions of the environment, until at last he sees only the object, and is conscious of nothing else. But in time, as the optic centres become exhausted and cease to respond to continued stimulation,

the visual sense likewise becomes extinct, and the subject is left in a condition of mental vacuity and 'senselessness.' He has been reduced from a state of polyideism, which is the normal condition of the healthy man, who is constantly receiving and balancing multiform impressions derived from all the avenues of sense, first, to a state of monoideism—the idea of a fixed image, upon which he must keep his eyes and attention; and, finally, to a state of vacuity, in which there is complete absence of ideas. Into this swept and garnished chamber of the mind ideas can be implanted by the hypnotist; and, as a ray of light thrown into a darkened room will show forth with exaggerated force and brilliancy from the contrast with the surrounding darkness and the exclusion of conflicting rays, so will the idea suggested to the imagination of the profoundly hypnotized subject operate with immensely increased effect from the absence of conflicting and corrective impressions derived from the whole environment.

As the patient, on recovering consciousness, in some cases may continue the speech or occupation which was interrupted by an injury to the brain, so the hypnotized person, on being aroused, will sometimes carry on a phrase or an action from the point at which it was broken off by hypnotic influence—thus showing how completely the brain, as the organ of mind, has been paralyzed. But whereas in the coma of disease the paralysis is absolute and complete, in induced somnambulism it is partially or entirely removable at the command of the operator. He can arouse any centre to more than its normal functioning activity, so that the subject, who a moment before was insensible to the fumes of strong ammonia held close to his nostrils, will now recognise the faintest odour; and he who now lies in a condition of muscular impotence will, at the word of the operator, perform extraordinary feats of strength. The same holds good with the expression of the emotions. From a state of abject misery, the subject may be suddenly transported to one of bliss, and be it noted that he shows both conditions far more markedly

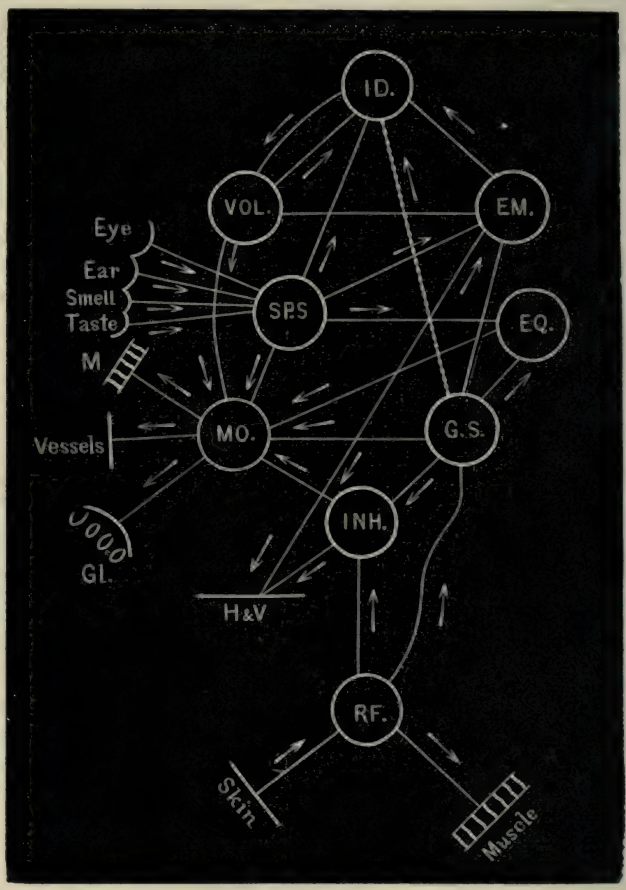
than he would do if awake; for in the normal state our emotions are subject to that inhibitory influence which we call self-control, and which is non-existent in the somnambulic subject, over whom each passion, each emotion that is called up, has for the moment an undivided sway.

If I am told to raise my arm, the order is conveyed to the auditory centre, and thence referred to the ganglionic cells of the cortex, in which the highest functions—attention, volition, comparison, etc.—may be supposed to reside; if endorsed by the will, it is despatched through the motor centres, basal ganglia and spinal cord, to the muscles, which perform the required action. Even if my will refuses to obey the order, it may happen that an involuntary stimulus is sent downwards, sufficient to cause some slight muscular movement, which, however, is promptly checked by the inhibitory action of the highest centres. But suppose the order is given in an imperative tone to one accustomed to obey the voice of authority—a soldier,* for example—it will probably be executed automatically, without any functioning whatever of the will; the command is referred from the auditory centres, where it is taken in, direct to the motor centres, and through the basal ganglia to the muscles of the arm. In such a case, a like order has been so frequently followed by its execution that the two have become cause and effect, and the action is automatic or cerebro-reflex, and almost beyond the man's control. A hypnotized subject is in much the same position; his intellectual centres do not work, and an order suggests its fulfilment without, and, indeed, sometimes contrary to, volition and reason.

* There is a well-known story of an old soldier who, while carrying home his Sunday dinner, was hailed by a practical joker, who called, 'Attention!' His arms immediately fell into the required position, and the dinner rolled in the gutter. Assuredly, volition had no voice in this matter.

The subjoined diagram (adapted from the 'Encyclopædia Britannica,' article 'Physiology') will assist the comprehension of voluntary and automatic actions.

A severe mental shock will sometimes induce this automatism; the various duties and actions of everyday life will then be gone through as in a dream, and often without leaving any recollection of their performance. A



Id., Ideational centre; Vol., Volitional centre; Em., Emotional centre; Sp. S., Centres for special sensations; Eq., Centre for sense of equilibrium; Mo., Motor centre; G. S., Centre for general sensation; Inh., Inhibitory centre; Rf., Reflex centre; M., Muscle; Gl., Gland; H. and V., Heart and Vessels. The lines show the association of one centre with the others, and the arrows indicate the direction taken by nervous impulses. Hypnotism may be supposed to cut off or inhibit some of these associations, *e.g.*, the volitional from the motor.

severe blow on the head will occasionally bring about a like condition—as in the case of a gentleman, aged twenty-one, a patient of mine, who was thrown from his horse while hunting. He subsequently recollected riding at the fence at which he came to grief, but had totally forgotten everything that followed until the end of the run, which lasted for about fifteen minutes after his fall. Yet I have the report of eye-witnesses, who state that he was up in a moment, mounted his horse, and joined the field as if nothing had happened; but that he wore a dazed expression, and made unintelligible answers to the remarks addressed to him. He is always a plucky rider, but on this occasion he surpassed himself, taking a dangerous fence which only one other horseman attempted, and which he would probably have avoided had his reasoning faculties been at work. He felt a severe pain in the vertex, which had been struck in his fall, and for a few hours remained in a somewhat dazed condition.

There is no memory of acts done in the somnambulic state, because that association of centres and balancing of one mental function by another which constitute ideation, self-control, attention, volition, comparison, and memory are for the time being rendered inoperative. A patient under hypnotic influence may be compared to a complicated machine, which is thrown out of gear, and yet can be so adjusted that some parts can be made to act independently of the others.

As regards the physical basis of the phenomena, recent researches in physiology enable us to form a fair working hypothesis. Heidenhain supposed that there must be anæmia of the brain, until he found that his brother could be hypnotized as easily as usual immediately after taking a physiological dose of amyl nitrite.

Dr. Barwise thinks nitrite of amyl, by lowering the blood tension, leads to congestion of the membranes of the brain, and that these exert direct pressure on the contained organ, and so empty its vessels. He finds that his best hypnotic subjects blush readily, and that they

commonly become flushed while being hypnotized. He also finds that persons may be more easily hypnotized if the head is bent back so as to obstruct the return of venous blood from the brain. He therefore supposes that hypnosis depends upon congestion of the membranes with coincident anæmia of the cerebrum.*

Dr. Gerald Yeo, late Professor of Physiology at King's College, thinks Heidenhain's inference that nitrite of amyl causes general congestion of the brain is not a necessary corollary of the fact that it produces flushing of the face. He supposes that in hypnosis we have a condition of partial and local anæmia of certain areas of the cortex.

Dr. Yeo has made a special study of hypnotism, and his lecture before the King's College Science Society in 1883 was almost the first serious attempt in this country to bring modern physiological science to bear on the subject. Starting from the analogy afforded by the innervation of the heart, which is supplied with excitor and inhibitory centres, he argues that the more complex an organ the greater will be the need of a double check action, and he considers the brain the most complex of all the organs. He supposes that the functioning of the cortical cells, which forms the basis of higher cerebration, depends, as does the activity of other organs, upon their supply of blood, and to regulate their supply he infers the existence of centres which he calls neuro-regulatory. Their action is of two kinds—neuro-inhibitory and excito-neural.

The excito-neural centres watch over the nutrition of the brain cells, and are, in fact, trophic centres for the cortex. The neuro-regulatory centres are kept *au courant* with the condition of each organ, and its wants and capabilities, through thin connecting fibres; and they act accordingly, either exciting or inhibiting their representative centres in the brain. When the blood-supply is cut off from the cortical centres the functions of higher cerebration are inhibited altogether or in part, and un-

* *Op. cit.*, p. 12.

consciousness or altered conditions of consciousness results. Some conditions of the organism cause a response from the neuro-regulatory centres in the form of an inhibitory impulse which puts the organ or function represented out of action, and others, on the contrary, convey a dynamogenic impulse to the regulatory centres. The influences which cause excito-neural action are stimuli having a great degree of intensity, *e.g.*, pain, noise, mental anxiety. The influences which produce neuro-inhibitory action with consequent decreased functioning of the cortical cells are muscular and mental fatigue (with the coincident accumulation of waste products), and monotonous continuous stimulation of a sensory organ. This stimulation causes an impulse resembling that due to local fatigue to be sent to the neuro-regulatory centres, and these respond by inhibiting the activity of the cortical cells.

Preyer is inclined to consider hypnosis as a cortical neurosis, dependent on disturbance of the functions of the gray matter, due either to its inhibition or excessive activity. He supposes that hypnotizability indicates an abnormal amount of instability of the cells of the highest centres, and that in hypnosis the nutrition of the cortex is altered by the accumulation in its cells of oxidizable waste products (lactates). Unless we can speak of normal sleep as a neurosis, I should object to the term being applied to its hypnotic analogue as confusing, and as somewhat committing us to a theory.

Dr. Lehmann, lecturer on Experimental Psychology at the University of Copenhagen, has published the lectures he gave in 1889, and his book is one of the best which have been written on the subject. He works out very carefully the causation of natural sleep and the points wherein it differs from hypnosis. He considers that hypnosis closely resembles natural sleep, but differs from it in that the process is arrested or cut short before complete unconsciousness is reached. Sensation depends upon attention, and attention implies increased supply of nutrition

to the part of the sensorium affected. In hypnotism parts of the sensorium are maintained in a state of activity by the attention of the subject being directed to them by the suggestions of the operator. There is increased nutrition of certain centres, with corresponding innutrition of others, and the phenomena produced are the outcome of these changes in cortical nutrition. In the waking state there is continuous stimulation of the vaso-motor centres proceeding from the sensorium, and cessation of mental activity from fatigue or other cause brings about a discontinuance of the stimulation, with resulting relaxation and dilatation of the cerebral vessels and blood stasis. Lehmann points out that functional activity depends on the amount of blood passing through an organ, and not on the amount present at a given time. In hypnosis he supposes there is a condition of tetanic contraction affecting the bloodvessels of the active part of the brain, and this tonic condition leads to increased rapidity of the flow of blood through them, increased nutrition of the part, and increased functional activity. The result of blood stasis from withdrawal of the stimulating influences arriving at the vaso-motor centres from the sensorium is drowsiness and sleep, and in ordinary sleep this condition affects equally the whole of the hemispheres. In hypnosis it is partial, and can be modified by the suggestions of the hypnotist, and the subject under his direction dreams a series of dreams. In the transformation of the natural into the hypnotic sleep the subject is so far awakened by the voice of the hypnotist as to be enabled to act upon his suggestions, but not sufficiently to regain the use of all the faculties. See also review in *Mind*, July, 1891.

Other observers consider that there is a condition of cramp of the arterioles of the brain; and all are agreed that delicate modifications in the cerebral circulation constitute the basis of the hypnotic phenomena. We have probably no drug which acts exactly in the same way as hypnotism, otherwise we might use it as a vehicle for suggestion, especially in the case of patients who are

insensible to the hypnotic influence. Cannabis indica presents certain analogous symptoms,* and apparently exposes its consumer to exaggerated susceptibility to suggestion. But there is this important difference. In hashish intoxication the suggestion is simply a natural sensory impression, received *spontaneously*, and greatly exaggerated. The hashish-taker sees a small sheet of water, and in his drug-induced dreams it becomes a magnificent river, a vast lake, or boundless ocean. He hears an Italian organ beneath his windows, and imagines himself listening to the orchestra at Bayreuth.

Dr. Barwise writes (*op. cit.*, p. 10), that when experimenting with the drug on himself, he imagined the slight noise made by someone in turning over the pages of a book to be a thunderstorm. Dr. Von Schrenk Notzing has written an exhaustive treatise on hashish, and he finds that some persons while under its influence are as susceptible to verbal suggestion as if they were hypnotized. One of the men experimented on was a medical student, who not only obeyed all the suggestions made to him while under the influence of the drug, but also carried out suggestions made the next day (post-narcotic sug-

* If the following story is correct (and I have no reason to doubt my informant), the action of chloroform may, under certain circumstances be considered analogous to hypnotism. At one of the large metropolitan hospitals there existed, about thirty years ago, a club of medical students, called the 'Chloroform Club,' the chief object of which was to test the action of narcotics, and especially of chloroform. The members met in each other's rooms, and consumed physiological doses of various drugs. On this remembered occasion chloroform was the narcotic chosen, and one of the members was, as usual, told off to keep sober and watch his companions. But the temptation proved too great for him, and he also inhaled a considerable dose of the poison Into this room full of drug-excited young men came a late member who was extremely unpopular with the others, and one of them shouted, 'Here's ——! Let us kill him!' The horrible suggestion at once took possession of the whole party. They flung themselves on the new-comer, and a tragedy would certainly have followed had not some students in another room heard the victim's cries of terror. They, of course, rushed in, and made a forcible rescue. The affair was hushed up, and the club dissolved; but some of those who took part in the episode, which in its weird horror reminds one of the situations of Théophile Gautier, are now respected members of the profession, and will remember the occurrence.

gestions), and that without having any recollection of the order. For example, he was told to return to Dr. Schrenk Notzing's house the following day, and to ask him for three cigarettes. This he did, and in the same awkward and shamefaced manner as often characterizes compliance with post-hypnotic suggestions ('Die Bedeutung narcotischer Mittel für den Hypnotismus,' p. 67).

In alcoholic and other forms of intoxication, there is commonly an exaggerated automatic action, as seen in gesture, speech, and general demeanour, with corresponding inhibition of the higher and controlling centres, and increased readiness to act upon suggestion; whether it be self-supplied by the senses, or from without, by the bystanders. It is known that epileptics are extremely susceptible to suggestion, and any action suggested to one immediately after an attack would probably be executed automatically, without volition, and without subsequent recollection of its performance. This point is noticed by Sir W. Gowers, and is interesting, as these subjects are peculiarly susceptible to hypnotism, perhaps because their cerebral centres are abnormally easy to dissociate and throw out of gear.*

With our present knowledge, it seems impossible to explain certain phenomena connected with advanced hypnotism. Some of these, which have often been attributed to clairvoyance, are undoubtedly the result of exaggerated perception. The subject will, under the stimulation of suggestion, read figures or letters at an amazing distance, will distinguish persons by a sense of touch too delicate to exist when the other faculties are at

* According to Richet (*op. cit.*), the normal sleep of young children is almost somnambulic, and in support of this theory he instances the case of his little boy, aged five, who remains profoundly asleep when his father goes in at night to caress him, but who murmurs a welcome and returns the embrace. The next morning the child is unconscious of what has passed. It must be the experience of all observers that not only in such a matter, but in other everday occurrences, a child is frequently in a condition resembling hypnosis, and this perhaps explains the fact that children are such satisfactory subjects for hypnotic treatment. The balance of the faculties has not yet been attained, and thus readjustment is easily effected.

work, will feel the apparently imperceptible currents of air set in motion by 'magnetic' passes, and will comprehend and act upon hints and whispers which are inaudible to the ordinary listener. *Why* should the hypnotized subject be deaf to all sounds except the voice of the operator, and hear and obey that voice, though it be but the faintest whisper, and the surrounding sounds a perfect babel? The waking of a tired mother at the feeblest cry of her infant, though loud noises are unnoticed by her, and that of Nelson's signal-lieutenant at the word 'Signal,' though the roaring of cannon had failed to arouse him, may afford an analogy, if not an explanation.

A peculiar species of phenomena is that in which a letter, or word, or object, is eliminated from the consciousness of the patient. For instance, A B is told that on awaking he is to write certain words, say 'Alexandra Palace,' without the letter *a*. He will do this, and in so rapid and business-like a manner that the observer (who had better try to do the like) must be convinced of the genuineness of the experiment. Or he is forbidden to use the pronoun *I*, when he will be at extraordinary pains to avoid the word, and will not once be betrayed into employing it, though, as in the case reported by Max Dessoir, he may use its equivalent in some foreign language. The subject may be wide awake and perfectly reasonable in all other respects, but this *idée fixe* is firmly implanted in his mind, though he is absolutely unaware of its presence. If shown his copy in which the letter *a* or the pronoun *I* is missing, he will see nothing wrong about it, and the delusion remains until he is told to return to his usual state, when the absurdity of the thing will be at once apparent, and he will perhaps deny having written the incorrect words or sentences.

Several varieties of aphasia may be functionally induced by suggestion. The subject may be rendered incapable of uttering a sound (complete motor aphasia), or can be made to reply to every question by a meaningless for-

mula, as in some of the pathological cases cited by Trousseau and by Gowers. He may be conscious or unconscious of the absurdity, just as in the pathological entity, and the condition may be modified in various directions. He may, for instance, be unable to pronounce the letter *e*, but able to write it, or *vice versâ*. We know that aphasia may occur from functional causes, as from a strong emotion, when one is rendered speechless by terror, indignation, or overwhelming joy or surprise;* and the induced aphasia of hypnotism seems to resemble this variety rather than that which sometimes occurs in the course of typhoid fever and from reflex disturbances. The subject is well worth the attention of physiologists, and its study may throw light on some morbid conditions connected with speech. The differentiation is very much finer than anything of this nature to be seen in disease, and requires correspondingly fine analysis. Dr. Gowers remarks on the deficiency of facts and the redundancy of theories connected with this subject. Hypnotic experiments may help to increase the former and prove or disprove the latter.†

Violent emotion may cause other effects than transient loss of speech. Charcot‡ gives the case of an intelligent man, who, after a violent paroxysm of rage, lost the memory of visual impressions. Though he could see objects, they all appeared strange to him, and he could

* Dr. Ireland (*op. cit.*, p. 273) cites a case of sudden *gift* of speech under the influence of exciting emotion. A well-known merchant in London had a son about eight years of age who was perfectly dumb, so that all hope of his ever speaking had long been abandoned. The boy was intelligent, and had no other infirmity. During a water-party on the Thames the father fell overboard, and the hitherto dumb boy cried out: 'Oh, save him, save him!' From that moment he spoke nearly as well as his brother-, and afterwards became an active partner in his father's business.

† By hypnotic suggestion reading may be rendered impossible (alexia). The subject may also be made incapable of writing (agraphia), and can even be prevented from expressing himself by signs (amimia). Sewing, drawing, and indeed every action, may be tabooed by the same means. (See 'Der Hypnotismus,' by Dr. A. Moll, p. 92, Berlin, 1889.)

‡ Quoted in Landois and Stirling's 'Physiology.'

not recognise his friends, nor even his own face in the glass. Injury to certain parts of the brain, especially the lower parietal lobe, may induce this 'psychical' or 'mind' blindness, and this condition can be exactly simulated by suggesting it to a sufficiently sensitive hypnotized subject. The association between the visual centre and the higher intellectual centres in which *memory* resides is inhibited in both cases.*

That suggestion acts by partially or wholly inhibiting the perceptive centres seems demonstrable; but how it does this cannot at present be explained. There is, of course, great scope for self-deception in hypnotic experiments; but if subjects of proved integrity are chosen (hysterical women and young boys are not so trustworthy as intelligent artisans), and if they are kept in ignorance of the phenomena which the operator desires to obtain, simulation need hardly be feared. Negative hallucination, as described on p. 339, is a complex condition, which I cannot explain, as some would do, by calling it mere clever acting. Sometimes, indeed, I suspect *unconscious* simulation on the part of the patient, as in the case of E. H——, who, when told not to see Dr. F——, carefully avoided looking in his direction, and refused to answer when he spoke to her, except once, when she looked puzzled, and answered him while looking towards me. She assured me that Dr. F—— was not in the room, but had been called away to see a patient; this I had suggested to her in the hypnotic sleep. On being told by me to see Dr. F——, she immediately looked at him, and expressed surprise at his sudden return. But in most cases the blotting out is complete, and the subject may even be pinched or pricked by the person designated as

* Partial or complete loss or impairment of all the special senses may be induced in a similar way by suggestion; *e.g.*, the subject may be rendered unable to perceive the odour of violets, while noticing all other scents, or to see red, while other colours remain distinct. The hypothesis that certain cells of the cortical perceptive centres are differentiated in the process of evolution to react to the special stimulus of certain sounds, odours, or colours, and that these are inhibited, is a tempting one.

invisible without feeling anything, and the invisibility may be extended to any article which he (the subject) takes in his hand.

The induction by suggestion alone of pseudo-paralysis in a limb is a curious phenomenon. I can say to E. F——, whom I have frequently put into a state of advanced somnambulism, 'You cannot move that arm or that leg,' and so evoke the idea of powerlessness, that for a few minutes the limb remains motionless; then with a sensation as of 'pins and needles,' power comes back to it, and she can move it freely. Max Dessoir describes how he influenced a postman whom he could not hypnotize in any usual way. He told him to make the movements required in stamping letters, and when he had done this for some minutes, cried in an authoritative tone, 'Now you cannot stop doing that!' The idea was fixed in the man's mind, and, in fact, he could not leave off. During his performance of an act that with him had become automatic, the higher centres, being inactive, were easily inhibited, and the hypnotic condition was then induced by suggestion. I have frequently seen Dr. Arthur hypnotize his patients by telling them to listen to his watch ticking, and the sound will send them to sleep. I sometimes use this method in persons whose sight is weak or defective. At Nancy, Bernheim has almost given up fixation of the eyes, and relies upon verbal suggestion alone. The patient, lying with closed eyes, hears the doctor's somniferous suggestions, and generally falls very quickly into the hypnotic sleep.

The case of Mrs. M——, a hospital nurse, is typical and interesting. She was first hypnotized by me in October, 1888, and since then I have hypnotized her frequently —perhaps two hundred times—generally to demonstrate various phenomena to medical friends. She is a person of little education, but has good natural ability, and is a clever nurse. I find her a somnambulist of an advanced type, with no memory on waking of what has occurred during the hypnotic sleep. As she was a good and

willing subject, I used to get her to obey my suggestions post-hypnotically; but on one occasion she took offence at some remark of a bystander, and told me she would never again do anything of the kind. Henceforth her reply was always *No* when I asked her to do anything on waking, and such suggestions were never carried out. After some months, however, I persuaded her to withdraw her opposition, and she now again goes through the little tests which I propose. I find, as Binet and Féré have observed in some of their cases, that this subject is quite unconscious of obeying any initiative except her own,* and invariably finds some reason for her conduct. For instance, she is told to move a lamp from one table to another, and if asked why she has done so, she replies that she thought it would look better in another place, or give some such plausible excuse. No one could be more surprised than she is when told that she has simply obeyed an order. And as in dreams no commands given seem ridiculous, and hardly any are deemed impossible to fulfil, so it is with such 'advanced' hypnotic subjects. Nevertheless, Mrs. M——'s resistance to suggestion seems to show that some personal control is maintained, and her intelligent replies to questions demanding calculation and reasoning, such as, 'What is the best route to the city? How much time is required to get there?' imply some working of the higher faculties.

Dr. F——, a foreign physician of much experience, attempted in my presence to hypnotize this subject. Without being aware of it, she was protected by my having frequently told her, while she was in the hypnotic state, that she must allow no one except myself to send her to sleep. Dr. F——'s attempt to do so made her uncomfortable, but not at all sleepy, until I told her that she was to be influenced by him. My embargo thus removed, a few minutes sufficed to induce her usual state of profound somnambulism, in which she was anæsthetic

* Dr. Auguste Forel records, also, the same experience. 'Der Hypnotismus,' etc., p. 31, Stuttgart, 1889.

and insensible to her surroundings. I now spoke to her, and she gave no reply, until Dr. F—— told her to do so, when she immediately answered my questions (*vide* note, pp. 121, 122).

There is another curious phenomenon obtainable with the above-mentioned subject, as well as with many other somnambulists—a compulsory automatic action brought about and maintained by suggestion *without* hypnotism.* Thus, I set Mrs. M—— to perform the action of 'twiddling her thumbs,' and tell her that she is unable to discontinue it. Though she laughs and protests, and is apparently in full possession of her faculties, she cannot leave off the movement until I give her permission to do so.

Dr. Ireland, writing on the double brain (*op. cit.*), quotes largely from Dr. Edgar Bérillon's book.† This author certainly has the courage of his convictions, for after giving many examples of the double-brain action, he records experiments which satisfy him that through the agency of hypnotism we can induce this double action. For instance, he will speak into the right ear of a subject in a profound state of hypnosis, and describe to her an amusing scene at a theatre; then into the other ear he will pour some tragic tale. The right side of the face will express pleasurable feelings, whereas the left side will, at the same time, wear a look of grief or terror. Dr. Bérillon defies anyone in an ordinary state of health, or even in hysteria, thus to produce the simultaneous expression of a double set of emotions. He makes the following inductions: '1. That hypnotism can suppress the physical motor and sensory activity of one hemisphere of the brain. 2. That it can give to each hemisphere a different degree of activity. 3. That the two hemispheres having an equal degree of activity, we can create for them

* Dr. A. Moll (*op. cit.*, pp. 192, 193) is of opinion that such obedience generally implies a slight degree of hypnosis, induced by the mere command in a susceptible subject.

† 'Hypnotisme Expérimental, la Dualité Cérébrale, et l'Indépendence fonctionnel des deux Hémisphères Cérébraux,' Paris, 1884.

at the same time manifestations varying in their seat, their nature, and their character.'.

That a transference of functional activity from one side of the brain to the other may sometimes be effected by hypnotism seems to be shown by the case of Louis V—— (described on p. 91). This subject was easily hypnotized, and in the hypnotic state would lose the right hemiplegia from which he was suffering, and walk quite naturally. When he was hypnotized, both his eyes were shut, as in natural sleep; and if either of them was forcibly opened the corresponding side of his body became cataleptic, while if both were opened the whole body took on this condition. If the right eye was opened while he was talking or reciting in the hypnotic state, he not only became cataleptic on the right side, but also aphasic, and the physician in attendance, Dr. Jules Voisin, came to the conclusion that this action produced an inhibitory effect on the left hemisphere, and consequently and inclusively on the normal centre of speech. When the eye was again closed, he took up his speaking or reciting where he had left off. The opening of his left eye in his 'first state' had no effect on his speech; but in his 'second stage,' during which his words and mode of expression were extremely childish, opening the left eye stopped speech, whereas opening the right eye produced no effect. This, according to Dr. Voisin's theory, supported to a certain extent by Drs. Burot and Bourru, showed that the speech centre had shifted sides. In his 'first state' Louis V—— used chiefly the left hemisphere of his brain, and in his 'second state' the right hemisphere, which, being less educated than the other, accounted for the imperfect character of the speech produced during its preponderance.

Dr. W. Ireland,* in his interesting volume of essays dealing with abnormal mental conditions, gives some curious examples of double consciousness occurring in the course of disease and from poisoning. He refers to

* 'The Blot on the Brain,' Edinburgh, 1885.

hashish-eaters being sometimes conscious of a double individuality, and quotes the well-known case of a drunken porter who, when sober, used entirely to forget where he had left his parcels, and remembered it only when he was again intoxicated—that is, when the brain was again in the same specific state which it had been in when he committed the action. Dr. Ireland also mentions the sensation of double personality sometimes experienced by a person suffering from severe illness, who has appeared to himself as two different individuals, one of whom suffered, while the other looked on and pitied him.

Draper, in his work on Physiology, refers to this point, and remarks that one never experiences three consecutive trains of thought, for the very good reason that our brains possess only two hemispheres. He considers that the two sides may sometimes act independently, and even inharmoniously, and thinks that double cerebration may be thus explained. Thus we may follow out a train of thought while giving a fair amount of attention to an address or sermon, or we may even be able, like Mr. Barkworth, of the Society for Psychical Research, to carry on an ordinary conversation while adding up a double column of figures. Of course the theory of a double action of the cerebral hemispheres need not be invoked to explain such everyday occurrences as being able to play the violin or piano whilst carrying on a conversation. Practised musicians can, we know, play difficult music while engaged in conversation, just as artists are able to talk to their sitters while painting them. But we need not invoke the theory of dual brain action to explain this, any more than we require it to explain how it is a sempstress can ply her needle and sing the while. In these cases continued practice has made the special movements of eye and hand automatic, and there is no question of employing the functions of higher cerebration. When the artist comes to a difficult passage or piece of work, he is seen to become silent and to devote all his faculties to its elaboration. The associated group of centres require the

control and leadership of the highest nervous arrangements.

The brain is, of course, a double organ, anatomically and physiologically, and though in normal life the two hemispheres are so functionally associated that they act as one, such cases as those I have cited seem to show what most observers are agreed in concluding, that under certain conditions the partnership may be dissolved, and one side may act independently of the other. In some cases of insanity the patient has been observed to ask questions and reply to them, as in two different capacities, and Dr. Ireland supposes that in such instances the two hemispheres are acting alternately. He suggests that the existence of such conditions may prove a key to the explanation of many cases of 'spirit-possession' and hallucination.

The left hemisphere is much more used than the right, and in general is proportionately more developed, though in left-handed persons the reverse is said to be the case. But although we may ordinarily use only one-half of our brain for certain actions, we can sometimes, in case of necessity, educate the neglected half to act when the other is injured. We may thus explain those curious instances in which, after an illness, previous education is forgotten, and the patient has laboriously to learn everything over again—to re-educate his brain, or rather to educate that portion of it which hitherto has been comparatively unused. Hypnotic suggestion, circumspectly used, might doubtless afford valuable assistance in such brain education.

The dissociation of the two sides of the brain, and the transference of preponderating influence from one to the other, certainly seems to afford a plausible explanation of many of the phenomena of advanced hypnotism. But it is not so easy to attribute to this dissociation and transference the therapeutic and other effects observable in the minor degrees of hypnotic influence with which the practitioners of the Nancy school are satisfied. Physio-

logical theories change as knowledge increases, and when they are proved to be erroneous they are apt to drag down in their fall the practice which has been founded upon them. Therefore, while avoiding mere empiricism, it is safer not to depend too much on any as yet unverified theory of hypnotic suggestion. Within the next few years a flood of light will probably be thrown upon this subject.

CHAPTER VII

Reality of Hypnotic Phenomena. — Simulation Tests. — Practical Directions for Medical Hypnotism.—Absence of Personal Element in the Nancy Treatment.—Method of Fascination.—Voisin's Success in Lunacy.—Forel's Opinion of the Treatment.—Some Diseased Conditions benefited by Hypnotism.—Medical Education essential for its successful Practice.—Aids to Hypnotism.

To the believer in the scientific certainty and therapeutic value of hypnotic suggestion, it is somewhat trying to be told, as he sometimes is, that the whole thing rests upon a foundation of error or misrepresentation. Sceptics, we find, divide themselves naturally into two classes: those who entirely deny the existence of the hypnotic state, or affirm that its production is so rare as to be hardly worth taking into account; and those who, while they acknowledge the reality of the psychical condition, refuse to believe in its utility as a remedial agent.

The former are a diminishing quantity, and must soon succumb under the accumulating evidence adduced by such scientists as Charcot, Richet, Hack Tuke, Moll, Heidenhain, Krafft-Ebing, Preyer, Beaunis, Tamburini, Lombroso, Bramwell, Myers, etc.

The attitude of the latter class is comprehensible and, indeed, natural; and it is right that the guardians of the public health should exercise a healthy scepticism and demand convincing evidence before approving a treatment of this kind, or admitting it into their practice.

The work of such practical observers and clinicians as Bernheim and Liébeault of Nancy, Voisin, Bérillon, Dumontpallier of Paris, Von Schrenk-Notzing of Munich,

Van Renterghem and Van Eeden of Amsterdam, Albert Moll of Berlin, Wetterstrand of Stockholm, Cruise of Dublin, Bramwell and Woods of London, etc., will soon supply the necessary therapeutic testimony—if, indeed, it has not already done so—and we shall see hypnotic suggestion take its place in the armamentarium of the medical practitioner in spite of the difficulties thrown in its way by charlatanism and impostors past and present.

The *argumentum ad hominem* is, as Richet* tells us, undoubtedly the best to use; and as medical men are often excellent subjects, it has sometimes been my good fortune to convince a friend, and at the same time benefit a patient, by putting a member of our profession into one or other stage of the hypnotic state.

That simulation and imposture are frequently practised at public 'entertainments,' I am not concerned to deny, though it is easier to procure a genuinely susceptible subject than to take the trouble of training a confederate. Public performers are generally careful to have with them some subjects whom they have frequently hypnotized, so as to be prepared for contingencies.

One must admit that the desire to please and to appear interesting will, especially among hospital patients, lead to a good deal of simulation, intentional or unintentional. But in private practice and among intelligent patients, simulation is a bugbear of which we need take little account. With experience, too, comes the ability to detect deception, and the practised hypnotist is on the watch for it,† and is very acute in perceiving its slightest tokens. And, in fact, the patient is, as a rule, *more* rather than *less* influenced than he supposes. He will frequently say that he has in no way lost control over his thoughts and actions, and will be surprised to find that he cannot

* 'L'Homme et l'Intelligence.'

† Charcot has devised an ingenious instrument, by means of which the tracings given by the involuntary movements of the arm in simulated catalepsy can be compared with the very regular and even tracing made on a revolving cylinder when the subject is in the genuine hypnotic state. This contrivance may prove useful in the detection of fraud. (*Vide* 'Diseases of the Nervous System,' vol. iii.)

open his eyes, or that his arm has become immovable at the operator's bidding. The very way in which he tries to open his eyes is characteristic of an altered condition. Instead of using the levator palpebrarum, he wrinkles his brows and energetically employs the frontalis. If at last he succeeds, it is only after great exertion, and the eyelid opens in a peculiarly slow and heavy manner. In the same way, if, after being a little more influenced, he is told that he cannot bend or otherwise move his arm, he will make violent efforts to do so with the wrong set of muscles, and will perhaps at last, with difficulty, effect a partial and jerky movement in the desired direction.

It is but fair to ask one's self, Why should a patient make pretence about hypnotism any more than about other medical procedures? If we give a prescription to remove neuralgia or rheumatic pains, we do not accuse our patient of simulation when he returns and tells us that the *mistura ferri* or *sodæ salicylas* has relieved or cured him, but rather attribute this good result to our remedy, and congratulate ourselves on its success. The therapeutic test is a perfectly fair and correct one, and as it is neither necessary nor desirable to produce the physiological action of drugs when we give them as curative agents, so it is needless to evoke or expect the phenomena of *le grand hypnotisme* in cases where we use suggestion as a remedy. A knowledge of the physiological action of a drug is necessary, as, without such knowledge, we should be using it empirically; and a familiarity with the phenomena of advanced hypnotism furnishes us with a key to the action of suggestion, as in the phenomena of poisons we find one to the action of drugs.

The method I usually adopt to produce the hypnotic state is that practised by Liébeault, and is undoubtedly the easiest and most rapid. The treatment is psychical, and attention to detail is absolutely necessary to success. The existence in the patient of any opposing idea, as of fear—or of a spirit of ridicule, or of decided hostility—or a consciousness of bodily discomfort, will render futile all

attempts to hypnotize him—at least, at the first trial. His mind must be at rest, his position comfortable, and the environment should be such as would favour the advent of ordinary sleep. It is sometimes helpful to hypnotize one or two patients in the presence of a newcomer, so as to arouse his imitative faculty and dissipate any nervous feeling he may have. And some friend should always be present during the entire operation.

The patient reclines on a couch or in an easy-chair, and I stand or sit beside him, and hold the first two fingers of one hand at a distance of about twelve inches from his eyes, at such an angle that his gaze shall be directed upwards in a strained manner. I direct him to look steadily at the tips of those fingers, and to make his mind as nearly blank as possible. After he has stared fixedly for about half a minute, his expression will undergo a change—a far-away look coming into his face. His pupils will contract and dilate several times, and his eyelids will twitch spasmodically. These signs indicate a commencing induction of the desired psychical condition. If the eyelids do not close spontaneously, I shut them gently, and the progress of sleep is generally helped by verbal suggestions, such as: 'Your eyes are becoming heavy; they are getting more and more heavy; my fingers seem indistinct to you' (this when the pupils are observed to dilate or contract); 'a numbness is stealing over your limbs; you will be fast asleep in a few minutes; now sleep.' It is sometimes an assistance to lay one's hand gently but firmly on the forehead.

In ordinary cases, the operator will find that the hypnotic condition has by this method been induced in from one to three minutes, and he may now ascertain what degree has been arrived at. This depends chiefly, if not entirely, on the temperament of the subject, and I consider it impossible to foretell with any certainty what stage of hypnotism will be reached by any person who has never yet been hypnotized. I do not, as a rule, make many suggestions at a first sitting, but I gently rub the

epigastrium and suggest a feeling of warmth in that part of the body, a general sensation of comfort and well-being, and an agreeable awakening. After a few minutes I tell the patient that he has rested long enough, and that he can open his eyes and arouse himself. He generally obeys at once, and says that he feels refreshed and comfortable. I ask him what he remembers of his few minutes' rest, and he generally tells me that he has heard every word I said to him, and also any other sound that there may have been, but he adds that he felt a great disinclination to move or speak until he was told to open his eyes. He finds the feeling of warmth, induced by suggestion and by gentle friction of the abdomen, very marked, and this sensation will probably continue for several hours. He is perfectly awake and quite himself before he leaves the house.

The feeling of warmth is an important symptom, and Dr. Liébeault is invariably confident of doing good to the patient in whom he can produce it, if the malady is a tractable one. Magnetizers naturally attribute this sensation to the passage of the magnetic fluid from the operator to his patient, but it seems to arise from stimulation by suggestion of the vaso-motor centres, and from a transmission to the part of increased nerve and blood supply. A sensation of cold can often be substituted by suggestion for one of warmth, as I have seen in cases of gastric ulcer and of congestive headache ; in such a case the physiological process is perhaps reversed. Suggestion without contact would probably suffice to produce this local action ; and there is no doubt that friction with a book or other small article has generally the same effect as hand-friction.

On a second visit, the patient will usually enter the hypnotic state more rapidly, and its degree will very likely be found intensified. Therapeutic suggestions may now be made, or, if it is desired, the extent of hypnotic influence may be tested. This is generally done by first raising the arm at an angle to the body, and telling the

patient to keep it there. If the cataleptic state has been reached, it becomes stiff and rigid in that position, and will remain in it for an indefinite time, corresponding to the subject's muscular development. If the arm shows no tendency to drop, a rotary motion may be given to it, and the patient told to continue this movement. If the third degree is reached, he will do so until he is ordered to desist. The tests of somnambulism may now be applied. The first of these is to speak to the patient and get him to reply. Another person is then told to address him, and if the questions he may put fail to elicit any response, it will be evident that the subject is *en rapport* with the operator only, and other tests may be used, such as tickling the nostrils with a feather to demonstrate that anæsthesia exists, and prove the depth of somnambulism. Finally, if all these tests point to decided somnambulism, post-hypnotic suggestions may be made. The patient may, for instance, be told to sit on a certain chair, to open some book at a particular page, or to write a sentence leaving out a specified letter. Negative hallucinations, delusions of the senses, etc., can also be suggested. I need hardly insist that such tests and experiments are quite inadmissible without the previous consent of the patient and the presence of his friends.

The patients who attend Dr. Liébeault's clinique are desirous and eager for the treatment, and he and Professor Bernheim have the advantage of possessing their faith and co-operation. It is, I believe, essential to have the patient's confidence, and the time spent in acquiring this previous to commencing operations is well employed. Failure in obtaining the patient's good-will may not only prevent success, but may even cause the process to produce an aggravation of the symptoms. I have had the opportunity of noticing this on several occasions, and now never attempt to hypnotize without having the free consent of the person most interested. Neglect of this precaution led to some trouble in one of my early cases. A physician asked me to hypnotize one of his patients, a

young lady suffering from chorea. She expressed a dislike to the treatment, and only gave an unwilling consent to it being tried after a great deal of argument. She was susceptible to a certain extent, but her sleep was irregular in character and very disturbed. When she awoke the choreic movements were decidedly worse; on each subsequent occasion a similar process had to be gone through, and no good result ever followed. When left alone she got well without treatment in a few weeks, and then took her revenge on me and hypnotism by writing letters about it to the papers! In these she stated that she had struggled with might and main, and with partial success, to retain consciousness, as she disliked the process, and did not believe in its utility; thus showing that the very first conditions of success were wanting in her case. Of course, I refer to the Nancy method of hypnotizing by 'persuasion,' as it is well called. There is another method employed by many of the platform operators and by some medical men under special circumstances—hypnotism by fright or compulsion. The state thus induced is akin to that produced in animals and in man by sudden fright or shock; and it resembles hypnosis, and may pass into it. Preyer calls this state cataplexy. Charcot's cataleptic state, produced by the sound of a gong or by the flashing of a brilliant light, corresponds to this state, and resembles the condition of a person surprised by a train at a railway-crossing, or transfixed with terror by an appalling sight, *e.g.*, the Head of Medusa in the shield of Perseus.*

Hypnotism, as I have already said, is merely a psychical preparation or vehicle for suggestion, and this condition being induced, it remains for the treatment to be applied. The suggestions vary, of course, with the nature of the malady to be treated. If headache is the chief symptom,

* Livingstone has recorded his sensations when in the clutches of the lion which lacerated his arm and was very near killing him. He says he felt no pain and was conscious of no fear while his eyes were riveted on those of the enraged animal. In fact, the emotional centres were inhibited, and he was practically hypnotized.

the head is gently rubbed, while the disappearance of the pain and its non-reappearance are suggested. If sciatica, the course of the sciatic nerve is rubbed, and the substitution of warmth for pain is suggested. If insomnia, the patient is told to feel sleepy at a certain time, and to sleep steadily through the night. If constipation, a motion is suggested at a specified hour—for instance, after breakfast. In treating rheumatic affections, the parts are well rubbed and the joints and muscles exercised by movements. In neurasthenia and spinal irritation, the spine is rubbed and kneaded. In cases of amenorrhea, the advent of the period is suggested at the time when, by inquiry, it is found to be due.

In moral cases, such as dipsomania, a dislike of stimulants and a freedom from craving or discomfort is suggested, as also are self-control and a desire for cure. The training and tact of the physician find full scope in the application of suitable suggestions, and also in the recognition of the amenability of a case to this treatment.

The results are often more pronounced and more rapid than in most lines of treatment, and a patient may awake relieved or cured of a long-standing pain or loss of function; but it is well that neither patient nor physician should expect too much, and marvellous cures are apt to be short-lived. There should, however, be a steady improvement from day to day, and if, after a few trials, no change is observable, I generally give up the case, as being unsuited for the treatment. Dr. Liébeault allows only a few minutes for each case, but in many instances it seems to me desirable to let the patient rest for twenty minutes or longer, for we may well suppose that during that period suggestions are working under a favourable condition of the nervous system.* The treatment should be repeated

* Professor Wood, of Philadelphia, writing to the *Lancet*, January 11, 1890, on hypnotic suggestion, which he has recently studied in Paris, and has introduced into his hospital practice, seems to consider that the hypnotic sleep alone is frequently sufficient to promote cure, and to think that Bernheim is wrong in attributing everything to 'suggestion.' I entirely agree with Dr. Wood that in certain cases of hysteria

at intervals of not more than two or three days; otherwise incipient improvement may be checked by a fresh relapse.

I find improvement progressive, and cure permanent when once achieved. But in many patients there is a tendency to give up when a certain amount of progress has been made; and this tendency should be strenuously combated. In moral cases, it is absolutely necessary to have the patient under trustworthy observation, so as to guard against deception and relapse. I now refuse to treat such cases unless the friends are able to give proper supervision; and even after the cure appears complete, the patient, so I consider, should be told to report himself at regular intervals for at least a year, for repetition and reinforcement of the suggestion.

My practice is to make three or four attempts to hypnotize, and if no effect is produced I feel that the subject is not susceptible. In this respect I confess I lack the confidence and perseverance of Dr. Moll, who seems to think that everyone can be hypnotized, by one method or another, in course of time. He relates how he tried one patient forty times! Dr. Milne Bramwell reports cases in which he has succeeded in inducing somnambulism after the patient has proved absolutely insusceptible fifty, sixty, and even seventy times—an experience which speaks equally for the faith and pertinacity of patient and physician. I have occasionally, in special cases, made five or six attempts, but so far I have almost invariably found that if no effect is produced at the third sitting, it is useless making further efforts—at least,

---

and nervous exhaustion and irritability the physiological rest enjoyed during hypnosis is a powerful and, perhaps, sufficient factor in the cure; but it is impossible, even in these cases, to eliminate curative suggestion, for where it is not expressed by the physician it is understood and supplied by auto-suggestion by the patient. Dr. Wood's remark that the atmosphere of the Nancy and Paris hospitals is 'heavy with faith' applies, fortunately, to all institutions where cure-work is carried on. In London, at present, we have not the advantage of this meteorological condition, but the results are sufficiently satisfactory in suitable cases.

for some time to come. It is quite probable that circumstances may change, and subsequent attempts be successful. I know one lady who has suffered intolerable pain from occipital neuralgia for six years, and who consulted me about two years ago with a view to trying hypnotism.

I tried six or seven times to hypnotize her, but was unsuccessful. I then advised her to put herself under Dr. Auguste Voisin, of Paris. He endeavoured to hypnotize her on thirty-five occasions, but failed, though he employed chloroform as an auxiliary. On her return to England I again made some futile attempts, and then sent her to Dr. Milne Bramwell, who then lived at Goole. He and his partner tried about 150 times, and at length succeeded in inducing partial catalepsy and sensation of numbness in one arm. But the patient could always open the eyes, and the pain was little, if at all, relieved. She writes to me that she has now been operated upon about 210 times, and expresses her intention of continuing the treatment, as it seems to offer more chance of relief than anything else she has tried. The lady is remarkably bright and intelligent, and one can only suppose that the intense and long-continued pain has made it impossible for her to attain the necessary abstraction of thought.

Dr. Bramwell mentions one case in which he was successful in hypnotizing a patient after having failed to influence her in sixty-five previous attempts. The patience of both parties was rewarded by the lady being very soon cured by hypnotic suggestion of pruritis vulvæ, which had defied treatment for several years.*

One frequently finds the degree of hypnotic effect varies. For instance, I hypnotized Mr. R—— in November, 1888, and noticed that he fell into the fourth stage. He was suffering from chronic bronchitis, and was in a low, depressed state of vitality generally. Subsequently I could never induce more than the second degree, for as his health improved he became less susceptible.

As regards personal qualification, I should say that tact

* *British Medical Journal*, February 28, 1891.

and confidence are the only requirements. Different patients require to be approached in different ways, and the somewhat imperious tone which is necessary in some cases would arouse fatal antagonism in others.

The education and training of a medical man naturally tend to the development of these qualities, and from my experience I believe that any medical man can, with a little practice, succeed in hypnotizing the majority of patients. Anyone can hypnotize some people, and there are others whom, practically, no one can influence. Between these extremes lies a third and comparatively small class, with whom it requires experience and practice to succeed, and it is the management of these cases which requires most time and patience. Doctors who have known nothing of hypnotism, except that they have seen me hypnotize two or three patients, have frequently gone home and at once been able to hypnotize their wives, children, and servants, and have only been stopped in their run of success by meeting a case altogether insusceptible or requiring very careful management. Dr. Bernheim in his Hospital Clinique, claims over 90 per cent. of successes, and four-fifths of the patients fall into profound sleep or somnambulism, whereas in his private practice this is altered in a remarkable degree, for though nearly the same percentage are influenced, only one-fifth or one-sixth fall into profound sleep without recollection on waking. The French seem slightly more susceptible than other nationalities, but Forel, at Zurich, Ladame, at Geneva, Moll, at Berlin, Van Eeden and Van Renterghem, at Amsterdam, Wetterstrand, at Stockholm, Tokarsky, at Moscow, Hamilton Osgood, in Boston, U.S.A., and other practitioners all over the world obtain nearly as good results.*

Perhaps the most successful hypnotic clinique in existence is that of Dr. Wetterstrand, of Stockholm. Dr.

* Cory says ('Hypnotism and Mesmerism,' Boston, 1888) that he has never succeeded in hypnotizing a Chinese, though he has experimented on several. The Orientals I have treated have mostly been good subjects.

Forel, of Zurich, who has visited Stockholm, has described to me his method of procedure, and has published an account of what he saw in a recent work.*

His two large reception-rooms are luxuriously furnished, and in them are a number of comfortable arm-chairs and sofas. From nine till one daily patients crowd in, and each one in turn is carefully examined by Dr. Wetterstrand. Only such cases as he considers suited are selected for the treatment, and the others are sent away with ordinary prescriptions and directions. Those selected for hypnotic treatment are admitted into the reception-rooms and told to rest quietly and watch the procedure on the other patients. All around him the visitor sees other patients comfortably reclining in different stages of hypnotic sleep, and the whole atmosphere of the place is full of drowsy associations and suggestions of cure. When Dr. Wetterstrand comes to him he is already half asleep, and his mind is fully prepared to act upon the suggestions made to him. Ordinary suggestions, such as tend to deepen the sleep and produce feelings of general rest and comfort, are made aloud for everyone to hear, but the particular suggestions applicable to each individual case are given in a whisper by the doctor speaking into the patient's ear. It will be remarked that every step in the method tends to impress the imagination. The preliminary examination which the patient anxiously undergoes in the hope that his case will be found suitable for the treatment; the admission of the selected cases into the inner rooms, about which there is a certain air of somnolency and expectation; the vision of other persons in different stages of sleep—all excite the faculty of imitation and the desire to sleep to the greatest degree possible. After so much trouble and such careful selection the new-comer would indeed be ungrateful for opportunities and undeserving of cure if he did not enter into the spirit of the place and prove amenable to hypnotism and impressionable to suggestion. Small wonder is it, therefore, that

* 'Des Hypnotismus seine psychophysiologische,' etc.

Dr. Wetterstrand has treated over 3,000 patients with such success that he finds only 5 per cent. are uninfluenced by hypnotism.* Dr. Bérillon adopts a very similar method in his clinique in Paris, and he rarely attempts to hypnotize a patient on his first visit or until he has been prepared for it by seeing other persons operated on. He, therefore, also generally succeeds in influencing his patients. Drs. Van Renterghem and Van Eeden, at Amsterdam, pursue a somewhat similar course and are equally successful. No physician adopting a psychical method of treatment can afford to ignore any legitimate means of influencing a patient's imagination. And the best way to attain this end is the assumption and maintenance of a firm and yet sympathetic demeanour. I am led, more especially, to thus enter into minutiæ by having observed the something like contempt some of the medical men I have met have expressed for what I may call the technique of suggestive treatment. I have seen a hospital physician, who believes in hypnotism, fail over and over again with his hospital patients because he has ignored the preliminary step of gaining their confidence and allaying their fears. To enter a ward surrounded with students, and to pick out a trembling woman and tell her, without the least preparation, that she is to be hypnotized and go to sleep, is to arouse all kinds of opposing emotions in her mind, and renders hypnotism, at any rate by the Nancy method, impossible. The same woman, if approached gently, and shown other persons put to sleep and awakened, would probably prove an excellent subject, and might perhaps be cured by the treatment. Drs. Van Renterghem and Van Eeden always impress upon their patients that the more or less powerless condition to which hypnotism will for a short time reduce them is for a definite object, and that object

* In a hundred cases Wetterstrand finds the following proportions:

5·43 per cent. are uninfluenced.
7·24 per cent. feel drowsy.
52·49 per cent. are unable to open the eyes.
34·84 per cent. are somnambulic.

attained, there will be no more after-effect from hypnotism than from any other medical procedure, that there is no weakening of the will, and that the induction of hypnosis entirely depends upon their volition and co-operation, and cannot be achieved without them. The patient's attitude should somewhat resemble that of a passenger who gets into a cab in order to go to a certain place. Having secured a decent conveyance and a respectable driver, he gives himself up to rest in the confident expectation of arriving safely at his destination. If, instead of sitting still and trusting to the coachman, he shouts out contradictory orders and, in the fear of being taken out of his way, even pulls at the reins, it is probable that his journey will be somewhat prolonged. Many persons can never be hypnotized, because they lack the power of composing their minds and fixing their attention for two minutes at a time.

During 1890 I treated 118 patients by hypnotic suggestion, of whom fifty-nine were men, fifty were women, and nine were children between six and fourteen.

Of the men I found ten were uninfluenced after repeated trials, and of the women twelve were insusceptible. Only one of the children proved insusceptible. As regards degree of influence: seven became deeply somnambulic—three women, two men, and two children. Thirty-three exhibited the cataleptic phenomena. The remaining fifty-five patients were influenced to a degree short of catalepsy, and many of them experienced only a slight torpor or heaviness of the eyes. They all, however, felt the glow of reflex warmth in response to suggestion, which is so important a characteristic of the hypnotic state.

Of the thirty-three patients on whom I tried the process in vain, five were absolutely insane and four were suffering from hypochondriasis almost amounting to insanity.

Of the remainder some were scatterbrained, and I could not get them to fix their attention, some were contradictious and would not remain passive, while some seemed to be over-anxious and too analytical. Two or three

were so dull and heavy that they fell into natural sleep of a profound lethargic character, in which they were insusceptible to suggestion.

But in a few cases there seemed to be no reason whatever why the patient should not be a good subject, and it is quite possible that on another occasion, or under a different operator,* they could be hypnotized.

The accompanying table will explain the ailments for which these ninety-five hypnotized patients were treated and the results of the treatment:

NUMBER OF CASES.	DISEASE.	CURED.	BENEFITED.	UNCHANGED.
8	Chronic alcoholism	4	1†	3‡
1	Tobacco habit	1	—	—
2	Morbid delusions	1	1	—
7	Hypochondriasis	1	3	3
4	Bad habits	2	2§	—
1	Melancholia	—	—	1
8	Neurasthenia	3	4	1
5	Insomnia	3	2	—
1	Morbid blushing	—	—	1
2	Megrim	1	1	—
9	Various chronic neuralgias	4	3	2
2	Epilepsy	—	1	1
4	Functional paralysis	2	1	1
1	Hystero-epilepsy	1	—	—
3	Writer's cramp	1	1	1
2	Stammering	—	2	—
2	General chorea	—	—	2
6	Dyspepsia of various kinds	4	2	—
4	Irregularities of the bowels	3	1	—
3	Nocturnal enuresis	2	—	1
8	Menstrual irregularities	5	3	—
3	Chronic rheumatism	2	1	—

2	Locomotor ataxy	—	2	—
1	Cerebral tumour	—	—	1
2	Post-apoplectic paralysis	—	2	—
2	Infantile paralysis	—	2	—
95				

* I have twice succeeded in hypnotizing patients after other medical men of experience had failed, and, on the other hand, two or three persons whom I could not influence have been hypnotized by other operators. But, as a rule, I have found that the person who cannot be hypnotized by one physician is not likely to prove more susceptible with another—the condition being similar in both cases.

† The attacks are rarer and less severe.

‡ There was a temporary improvement in all these cases, followed by relapse.

§ One relapsed after twelve months.

I have not included in the foregoing list a considerable number of cases where I have used hypnotism simply as a palliative in ordinary general practice and in the course of acute disease; *e.g.*, in tickling laryngeal cough occurring in the course of pneumonia, colicky pain in typhoid, restlessness in endocarditis. Neither have I included cases in which I was only consulted once. Hypnotic treatment being comparatively novel, a number of persons come to the hypnotist more out of curiosity than for any wish to be cured, and others come with most exaggerated expectations. As an example of the latter class I may cite the case of an elderly gentleman who sent for me and asked me to hypnotize him in order that I might disperse an abscess, and so cheat the surgeon's knife. On examination I found a large abscess in the perinæum almost ripe for lancing. I succeeded, with some difficulty, in inducing a gentle and pleasant languor, in which I left him, after suggesting diminution of pain and a good night's sleep. These suggestions were fairly well realized, but the patient was sadly disappointed, because the surgeon had to open the abscess on the day following. A medical man once called upon me with even greater expectations. He was on his way to his dentist to have a troublesome molar extracted, and he looked in to see if I could not anæsthetize by hypnotism, and thus render gas unnecessary. Needless to say I did not succeed in gratifying him, and I am afraid he left me thinking very poorly of an agent which could not be evoked in its most advanced degree at will.

Two or three ladies have called upon me and told me that their husbands were in the habit of drinking too much wine, and have asked me to treat them without their knowing anything about it. They expressed much disappointment when I had to tell them that the patient's wish to be cured was an essential preliminary in such cases.

In my own practice, during the years 1888-89, I have found the following results:

Somnambulists	32
Profound sleepers	35
Light sleepers, or somnolent	88
Doubtful	9
Uninfluenced	42
Number of persons operated on	206*

All classes of society are represented in this table, which does not profess to be anything but a record of a somewhat limited personal experience. The English uneducated classes have an invincible distrust to novelty in treatment, and to this I attribute my almost complete want of success hitherto in public institutions. On most occasions, when I have talked to the patient and got him to come to my house, he has been easily hypnotized, and I have no doubt but that when hypnotism becomes a recognised treatment in hospitals, English experience will not differ widely from that of Nancy. One of the somnambulists is a doctor in large general practice. My oldest patient was a gentleman of eighty-two, who fell into the second stage, and was cured in a few days of an attack of gouty sciatica, which had always previously lasted for weeks. He has been my patient for seven or eight years, so perhaps the therapeutic test is admissible here. My youngest patient was a child of five, who fell into profound sleep at once. Most of the somnambulists are women of neuropathic predisposition, but very few of them had ever had any attack of ordinary hysteria, and many of them are hard-working clerks or good household

* Ten years' further personal experience of hypnotism proves to me that these figures are fairly representative. In 1894-95 a committee was appointed by the Society for Psychical Research to make some experiments in thought-transference and other phenomena in the hypnotic state, and we advertised in a newspaper for subjects. Twenty-six youths were selected from a large number of applicauts, and all these stated that they had never been hypnotized before. Eighteen proved hypnotizable, or 70 per cent., but of these only abont one-third were influenced to the extent of somnambulism.

The young men were of the junior City clerk class, and we found the most intelligent were the best subjects.

managers. Five of these, however, are boys of ordinary types apparently, and three are adult men of perhaps more than average ability and inteiligence. The profound sleepers were generally epileptics or persons of phlegmatic temperament. I have never seen any untoward symptoms arise from medical hypnotism, and I can hardly conceive such a thing possible with ordinary care and gentleness.

I am quite certain that the patient has in no way felt subsequently influenced by the operation, except in the direction suggested by me and wished for by himself. The Nancy treatment is essentially impersonal, and it is the patient who hypnotizes himself under the suggestion and guidance of the physician, and the curative effect gained is the result of concentration and direction of the patient's own faculties and functions. The somnambulist might, I believe, be made, by frequent induction of hypnosis, to do foolish, and even criminal, acts, but no suggestion made to an ordinary subject will be executed unless it be in accordance with his wish. For instance, it would be useless to suggest to a stanch teetotaler, in any stage of hypnosis short of somnambulism, that he should drink brandy. The suggestion would defeat its end by arousing indignation and disgust. Such a suggestion, opposed to his moral sense, made to a somnambulist, might be obeyed even the first time, but it would probably require frequent repetition to break down resistance and overcome his individuality.

If the method described for producing hypnosis fails, or loses its effect, I use a modification. Instead of the fingers the patient may be told to look at a bright metal disc or coin, or the skin of the forehead may be gently rubbed while the gaze is fixed on a distant object. Sometimes verbal suggestion tends to keep a patient awake instead of inducing sleep, and in many instances methods will have to be devised to meet different idiosyncrasies.

The method of fascination is, I consider, inapplicable and objectionable in ordinary medical practice, as it intro-

duces too much personal element into the operation, and induces a state of complete automatism, in which the subject's *ego*, or personality, is entirely suppressed (Binet and Féré). It is practised by looking fixedly and pertinaciously into the subject's eyes at the distance of a few inches, and at the same time holding the hands. In a few minutes all expression goes out of the face, and the subject sees nothing but the operator's eyes, which shine with intense brilliancy, and to which he is attracted as a needle to a magnet.

Auguste Voisin adopted this plan with insane patients, and sometimes succeeded when he had failed by all other methods. In such cases, of course, any means are permissible, as by hypnotism and suggestion he has succeeded in cutting short attacks of mania, and curing various intractable mental conditions.

There are objections to this method also from the operator's point of view. If the subject, or patient, is refractory and the operator tired, it may happen that the natural sequence of events is reversed, and the operator becomes hypnotized instead of the patient. Braid mentions several cases where this took place, and it has several times happened to Liébeault. On one of the few occasions on which I employed this method I nearly succumbed to the continued strain and became conscious of a curious inhibitory influence stealing over the muscles around my mouth.* Fortunately, the patient just then

* The mouth is generally acknowledged to be the most expressive feature, and its movements are less under the control of the highest centres than those of other parts. The man who can face an enemy without flinching is often unable to control the twitching of his mouth under circumstances of emotion. It seems to be especially subject to inhibitory influence, and a drawing in the muscles about the mouth often precedes any other symptom in the coming on of hypnosis. A middle-aged physician consulted me for sleeplessness in 1889, and asked me to hypnotize him. I found him susceptible to about the second degree, and having made some suggestions, I left him alone for a quarter of an hour. On my return his eyes were open, and I spoke to him; but he made no reply, and pointed to his mouth. In a few moments I understood what he meant, and proceeded to apply friction to it and told him to open it. He told me that he had not lost consciousness, and had opened his eyes at the expiration of the ten

closed her eyes and passed into a profound sleep. The method by fascination is also extremely fatiguing, and where prolonged staring at an object is necessary, it is best to employ Luy's rotating mirror.

Moll points out that the disagreeable effects sometimes seen in the first induction of hypnosis by other means than simple suggestion are due, not to the treatment, but to the patient's fears, and he says he has noticed similar symptoms accompanying the use of electrical appliances in nervous persons. I once hypnotized a hospital patient who became slightly convulsed and then passed into a very hysterical state. She confessed that she looked upon the process with great fear, as being very 'uncanny.' Dr. Bramwell relates how, in one of his cases, hypnosis was ushered in by a slight unilateral convulsion, but this did not prevent the operation being followed by cure.*

As regards the hypnotizability of different types—taking Sir B. W. Richardson's classification of men into animal, intellectual, nervous and their combinations—I should say that the persons of the animal type, large-framed, muscular men, of somewhat slow intelligence, but placid and easy-going temperament, unless aroused, are the best subjects. I have had several such among my somnambulists. Persons of the emotional type are not so easy to hypnotize, but once influenced are probably the best subjects for psychical experiments. I have seen a great many somnambulists of this class, and I think that any danger which may accompany hypnotism is only likely to occur in such subjects. Men of the purely intellectual type are not easily hypnotized: their minds are too

minutes I had told him to keep them closed; but he found he could not open his mouth, and there he had to lie speechless until I appeared and unlocked it. I had made no such suggestion, and can only explain the occurrence by supposing that I had unwittingly passed my fingers over his mouth in such a way as to suggest to him the idea that it was closed, which idea was carried into execution. The gentleman, who is an M.D. of London, was in a nervous state from want of sleep, and hypnotism would probably have done him good, but after this experience nothing would induce him to submit to the process again.

**British Medical Journal*, February 28, 1891.

analytical, and they are, as a rule, too unwilling to allow their will to be in abeyance. Nevertheless, their confidence gained, they sometimes make good subjects, though I have never seen a somnambulist of this type. A considerable number of my patients have belonged to mixed types—animal-emotional, which Dr. Richardson rightly says is not a pleasing combination; animal-intellectual, which is an enviable balance of qualities; and emotional-intellectual, a class comprising a very large proportion of brain-workers, and to which most geniuses belong. I have found hypnotism easily applied and extremely beneficial in the treatment of the neuroses to which this last class is especially subject. I have rarely reduced them to a state of somnambulism; and, as their minds are generally receptive, such reduction is not necessary. Undoubtedly the most difficult subjects to influence are those of weak and fidgety character, who are unable to look one in the face or fix their attention—their eyes being an index to their minds. I need hardly say that such a person as a medical man, who offered me five pounds if I would hypnotize him then and there at a medical meeting, is not hypnotizable unless he is able to change his mental attitude.

That insusceptibility to hypnotism is not a sign of intelligence is well shown by the fact that imbeciles and idiots are not hypnotizable. One of the severest rebuffs I have ever encountered in my professional experience was inflicted on me by a girl patient, an inmate of Paddington Infirmary. She was of extremely low order of intelligence, and I suppose her bringing-up had made her very suspicious of everybody and everything. She was suffering from slight chorea, and it was thought that hypnotism would do her good. However, I exhausted the different methods in vain, and at length the patient flung my arm on one side, exclaiming, 'I'm not asleep, and ain't a-going to!'

The physician in charge of a large workhouse infirmary recently asked me to try hypnotism in his wards, and he

picked out for me some suitable patients, as he thought. They were three broken-down hysterical women of low mental power, whose teeth chattered with fear when I looked at them. Of course such persons are most difficult to hypnotize, and one can only hope for success after repeated trials. I explained this to Dr. R——, and asked him to let me try on some more promising subjects, suggesting himself, his two assistants, and a ward nurse. They agreed, and he, one of the assistants, and the nurse proved excellent subjects.

On the other hand, John Hunter has recorded (Hack Tuke) how he nearly succumbed to the wiles of a mesmerist, and only kept himself awake by fixing his attention on his great toe, in which he was expecting an attack of gout.*

A few years ago I was asked as a matter of charity to try the effect of hypnotism on a poor elderly lady afflicted with disseminated spinal sclerosis. She was brought to my house and laid on a couch every day while for half an hour I practised the various hypnogenic methods upon her. But all my efforts were in vain, and after a few sittings I gave her up. About a year afterwards I heard through a friend that this patient was giving thanks to Providence for having saved her from my wiles, and she attributed her deliverance to having repeated prayers to herself during the process I adopted. She had consented to see me to oblige her friends, but had taken good care to render my efforts nugatory.

The late Dr. Voisin's practice requires a few words of

* The peasant women of Brittany are said to send their children to sleep by making them look at a bright ball suspended over their cradles. This, the rocking of the cradle, and the monotonous song which nurses chant to infants, are distinctly hypnogenic agents acting by the monotonous and continuous stimulation of one sense. It is possible that children yield more quickly to such influences than adults because their highest centres are as yet undeveloped, and therefore are more easily acted upon by inhibitory impulses proceeding from below. It is probable that the sleep of young children is of less mixed causation than that of adults: it is the result of inhibition almost entirely, the chemical products of cerebration which Preyer supposes exercise so soporific an influence being a *quantité négligeable*.

explanation. Many observers contend that as hypnotic suggestion is essentially a psychical treatment, and dependent for its success on healthful stimulation of the brain centres, it is inapplicable when the central organ is diseased. It is certainly most difficult to hypnotize the mentally affected, whether the condition be mania, dementia, melancholia, or idiocy. Nevertheless, Voisin finds he succeeded in about 10 per cent. of cases. But his physical strength, enthusiasm, and patience enabled him to do what few men would care to try. He used to spend an hour a day attempting to hypnotize one patient, and felt amply rewarded if after twenty operations he achieved an alleviation or cure. When he read his paper before the British Medical Association at Leeds, in 1889, his listeners could only express astonishment at his method and its results. Dr. Voisin has done much good work in other branches of medical science, and practises with such openness and publicity at the Salpêtrière, that no one can fail to be impressed by his testimony.

Personally, I have succeeded in somewhat benefiting melancholia in two or three cases, and in removing slight but troublesome and long-standing delusions in several instances; and in a case of retarded brain development in a boy considerable improvement is observable; but in mental diseases generally, I have, as a rule, failed to produce the slightest hypnotic influence.

Dr. Van Eeden considers that hypnotic suggestion will remove delusions in their early stage, while the patient is still aware of their falsity; but that when they have become established and a part of the personality, hypnotism, even if induced, can be expected to do but little good. This exactly coincides with my own experience, though in one case—that of a medical man who believed himself to be under the mesmeric control of a number of persons—I succeeded in greatly mitigating the symptom. I told him that I should be able to render him insusceptible to hypnotic influences other than my own, and my suggestions being thus more or less in a line with his thoughts,

he was capable of grasping them. He came to me in a very depressed condition, but about twelve operations served to greatly modify the trouble. Though he still, from time to time, heard voices, he no longer dreaded them, and felt he was able to laugh at the threats they conveyed. He has been enabled to resume his practice, and has greatly improved in bodily health and in capacity for work.

A curious and typical case of this kind was that of a retired tradesman who consulted me in 1896, and asked me if I could free him from the mesmeric control of H.R.H. Princess X——. He said he was a stanch republican. About two years before he was visiting Windsor Park, and was sitting on a bench when the royal lady passed. She looked at him, but he did not rise or raise his hat, an omission which he said caused her to look angrily at him. He immediately felt a sharp pain in the back of his head, and he had been subject to this ever since. He was quite convinced the Princess had thrown a spell over him, which she exercised from time to time to punish him for his want of courtesy. I thought I might succeed in removing the idea, but failed to do so. When I tried to hypnotize him, he said the lady put forth extra power, and neutralized my efforts; probably he will die with that delusion still dominant.

But there is a form of mental disorder which, though not amounting to insanity, causes intense suffering, and which is not uncommon. I refer to obsession by obscene thoughts. Students of the religious history of the early Church, and of the lives of Christian and other saints, know how common this form of derangement was. The temptations of St. Anthony materialized were popular subjects for the old masters. I have been consulted in many such cases, and have succeeded in several instances in removing the morbid ideas, and restoring the patient's peace of mind.

Two of my best cases were clergymen of exemplary life, and I have frequently found that it was men of the purest

life and with the highest ideals who were victims of these thoughts. An extremely intelligent patient who went abroad after a course of treatment which he said cured him came to see me recently for a renewal of the suggestions. He told me that he had been enabled to keep his imagination under control ever since, but that he felt that it was once more getting the upper hand. Renewed suggestion again had the desired effect. He was a middle-aged man, happily married, and had several children.

In no country have the phenomena of hypnotism been more carefully studied than in Italy. The names of some of the principal investigators — Lombroso, Tamburini, Sepilli, Tanzi, Morselli, Vizioli, Bianchi—are sufficient guarantee of the thoroughness of the work done.

A Commission of Italian physicians has been considering the therapeutic value of hypnotism, with special reference to its applicability in insanity and mental affections. After exhaustive researches, they have come to the conclusion that hypnotic suggestion may be efficacious in dipsomania and the psychoses which are based on hysteria, but that in other forms of mental disease favourable results are only obtainable in a few cases. The Commission put the matter to the test by experimenting with great care and patience on fifty-six mental cases—thirty-two men and twenty-four women. Of the men, eight were affected with slight mania, nine with melancholia, eight with epileptic phrenosis, two with fixed ideas, and three with paranoia. Only two of these proved hypnotizable—one epileptic and one lypemaniac. Of the twenty-four women, four were affected with slight mania, nine with melancholia, seven with epileptic phrenosis, two with fixed ideas, and two with paranoia. Only eight of these proved hypnotizable, and of these three were hysterical, one melancholic, and four epileptic. In the other cases no effect was produced. The degree of hypnosis produced was generally slight, and somnambulism only ensued in three cases—two of which were

hysterical and one epileptic. As regards therapeutic results very little was achieved in any of the cases. In the opinion of the Commission, morbid auto-suggestion is an almost insurmountable obstacle — first, against the success of hypnotism; and, secondly, against the fulfilment of the curative suggestions. The Commission came to the conclusion that hypnotism was therefore applicable in only a few mental diseases, but they experimented on and reported in favour of the systematic employment of therapeutic suggestions, without hypnotism, to the treatment of insanity. They found that suggestion made in the waking state is the most effective and reliable means of cure in mental diseases, and to it are due, almost entirely, the beneficial effects of the asylum—which represents a real suggestive surrounding.

'Summarizing now the results of our experiments, it appears that hypnosis was most readily obtained in cases of hysterical insanity, and in a few cases of epileptic insanity, but in other forms of mental alienation, despite our proceeding in accord with all the experimental rules, hypnosis, excepting in one case of anxious melancholy, was impossible. As regards therapeutic suggestion, made during the hypnosis, we are unable to report any actual results, excepting the case of hysterical ischuria described by Funajoli, though in some cases the hypnosis reached the degree of somnambulism, in which, according to Bernheim and others, the greatest susceptibility of the sleeper was observed. If, therefore, we may judge collectively of the result of our researches and of those made by the observers cited by us, we must conclude that a suggestive hypnotic therapeusis cannot be established, in the form of any general rule, as a means of cure in mental diseases. It seemed to be effective almost exclusively in cases in which the psychopathic phenomena were connected with a hysterical neurosis, or in dipsomania. In these special conditions of the psyche, it seems that hypnosis is obtained with sufficient facility, and the suggestion succeeds in modifying the characters, bridling the impulses

and bad habits, reviving the affections and sentiments, and removing morbid ideas. On the other hand, in the acute and chronic forms of paranoia, in states of mental weakening with delirious ideas, in grave forms of melancholia and mania, it is very rarely, if ever, that hypnosis can be obtained, or that suggestion alone succeeds in effecting the disappearance or the amelioration of those morbid phenomena which are the consequence of an abnormal organization, or of profound alterations in the cerebral mass.

'The results of therapeutic suggestion in mental diseases being thus examined, it seems to us that we may assume the following principal conclusions:

'1. Therapeutic hypnotic suggestion cannot be instituted as a general means of cure in the treatment of mental diseases, owing to the difficulty of hypnotizing the insane.

'2. Hypnosis succeeds most readily in the hysterical and epileptic.

'3. The most certain results of hypnotic therapeutic suggestion have, up to the present time, been obtained in the psychoses depending on hysteria and dipsomania.

'4. Hypnotic suggestion may be employed when the insane submit to it of their own accord, and derive benefit from it. The physician should use it with great caution, and take account of the hurtful effects which, in certain cases, may be produced.

'5. Therapeutic suggestion made in the waking state is the most reliable and effective means of cure in mental diseases, and to it almost solely are due the beneficial effects of the asylum, which represents a real suggestive surrounding.

'6. In cases of melancholia without delirium, cases of fixed ideas, cases of alcoholism, and in slight forms of stupor, suggestion methodically repeated in the waking state, in order to combat the morbid phenomena, may prove effectual.

'7. In the chronic forms of paranoia suggestion has never given favourable results.'*

It will be seen from this summary that the Commission advises the systematic employment of suggestion without hypnotism in some forms of mental disease. They were led to this conclusion by finding that a considerable number of the subjects whom they tried in vain to hypnotize were amenable to, and responded to, simple suggestion repeated regularly over considerable periods of time. In this way they succeeded in removing fixed ideas, *folie de doute*, and incipient melancholia in several cases. They also cured by this means a drunkard, whose daily allowance of alcohol was ten to fifteen bottles a day; at least, he reduced his allowance to one bottle a day. They found simple suggestion proved effectual in several cases of stupor of the first degree, by removing the state of arrest which paralyzes the will and the ideational faculties.

Dr. Percy Smith and Dr. A. T. Myers made trial of hypnotism in a series of cases of insanity at Bethlem, and the conclusions they came to are very similar to those arrived at by the Italian investigators.†

Dr. Forel, of Zürich, finds he can hypnotize even more than 10 per cent. of the insane who are confined in the public asylum, of which he is superintendent, but he expresses great disappointment with the result (*op. cit.*). Even when he has obtained advanced somnambulism, so that the patient has proved anæsthetic, and susceptible to negative hallucinations, he has often failed to remove a fixed delusion. For instance, Madame A—— fancied herself Madame B——. She was very susceptible to hypnotism, and Dr. Forel assured her in the somnambulic state that she was Madame A—— and not B——. She only shook her head, and even in this state refused to part with her delusion. Dr. Forel, however, obtains

* 'Therapeusis of Mental Diseases,' by Dr. G. Sepilli, translated from the 'Archivio Italiano,' in *American Journal of Insanity*, 1891.

† 'On the Treatment of Insanity by Hypnotism,' *Journal of Mental Science*, 1890.

good results in mental troubles of emotional and hysterical origin, and altogether is a strong disciple of the school of Nancy.

Dr. Forel showed me a curious condition of partial or complete analgesia which he is able to induce by simple suggestion in subjects whom he has frequently hypnotized. I saw him go up to strong, able-bodied German-Swiss attendants at his asylum, take them by the arm or hand, and tell them they had lost sensation in their right hand, left eye, or some other part; one could then prick the conjunctiva, or pinch the hand without causing the least sign of pain or discomfort, though the subject would be apparently in full possession of all her faculties. It is common enough for dentists and surgeons to assure their patients that this or that procedure will not hurt, but the affirmation does not, as a rule, make much impression. Dr. Forel's assertion, however, did really paralyze the sensory nerve fibres, or inhibit the functioning of their cortical centre. I have been able, in a few cases, to copy this experiment, and notably in one case—a somnambulic gentleman of thirty-five of good bodily and mental health. Friction of a localized area of skin will produce anæsthesia in a few seconds, and he will then be quite unconscious of any irritation applied to it. On the other hand, a suggestion of hyperæsthesia will be followed by increased sensibility to impressions. This gentleman, though such a susceptible subject, is now quite insusceptible to the hypnotic suggestions of any save his two medical men, and his individuality has been strengthened by hypnotic treatment. (For anæsthesia induced by suggestion without hypnotism, see p. 76.) Forel made practical use of hypnotism in a peculiar way. The institution was undermanned, and he found the attendants whom he had to employ to look after suicidal patients at night required to be off duty during the day, and so reduced his staff. He hit upon the plan of hypnotizing these attendants, and telling them they might sleep, but that any attempt on the part of the patient to get out of bed would wake

them. He found his plan quite successful, the attendants got a fair allowance of sleep at night, and were able to work during the day.

Alcoholized persons are generally good subjects for the treatment, but I have never succeeded in hypnotizing a person for the first time while in a state of intoxication. It is necessary to wait until the first effects of the stimulant have passed off. The effect of hypnotic treatment in chronic alcoholism is very marked. The patient often first comes under observation suffering from the physical effects of his indulgence. Probably he has subacute gastritis with morning sickness, furred tongue, flatulence and heartburn, headache and heaviness in the head, coldness of the extremities, with weak, irritable pulse and irregular action of the bowels. These symptoms, as well as their mental accompaniments—languor or extreme restlessness, despondency, and irritability—very speedily yield to the treatment, so that it is no uncommon thing to see the chronic drunkard well on his legs within a week.

I have tried the action of various drugs as aids to producing hypnosis in intractable cases, but neither subcutaneous injections of morphia, inhalation of chloroform or ether, cannabis indica, nor bromides, have seemed to exert any marked effect in that direction. (See p. 207.) Hypnotism seems a psychical condition *sui generis*. Alcohol, however, appears to predispose to hypnotism, and I frequently find a subject is more amenable after a good meal than he is before it. Hypnotism practised in a rational manner is not fatiguing or trying in any way, and no concentration of the operator's mind, or direction of his will, seems to be required. Liébeault is old and not robust, yet he hypnotizes sometimes as many as forty people in a morning. The idea of personal influence and magnetic attraction so industriously promulgated by interested public performers, and so objectionable to most people, is entirely discountenanced and denied by scientific practitioners.

In the foregoing remarks an endeavour has been made to answer many questions which are constantly being put to the practical hypnotist. The answers are founded on experience which it is in the power of any medical man to verify. The cases described in the following chapter are by no means exceptional, but are fairly illustrative of the use of hypnotic suggestion in ordinary practice. The results are certainly no better than would be attained by any trained medical man using the same method with a due regard to its technique.

Dr. Liébeault never attempts to hypnotize a patient for the first time if there is a spasm of pain, an access of retching or vomiting, or great emotional disturbance. An attempt to employ suggestion under such circumstances would almost certainly result in failure, and would endanger the success of future efforts. I always wait until the paroxysm is over, or, if the pain is continuous, I give an anodyne, and only try hypnotism when the disquieting symptoms are veiled by the drug.

After the patient has been thoroughly accustomed to the treatment, it is often possible to hypnotize even while he is suffering great pain, as I have seen in cases of acute rheumatism and neuralgia. But even when the patient is a good subject pain may render the process of no avail. Under such circumstances I again have recourse to an anodyne, and when the severity of the pain is subdued there is rarely any further difficulty in inducing the usual degree of hypnosis.

As an example of this, I may refer to the case of a gentleman who came to me to be hypnotized for locomotor ataxy. After the second sitting he experienced no more pains for nearly three months. Then he got caught in a storm, and sat for some time in his wet clothes. A violent attack of pain came on the night following, and he got to my house with much difficulty the next day.

The lightning pains in his thighs were so severe that they made him scream out, and they were almost continuous. He was only susceptible to the first degree, and

it would have been useless to have tried hypnotism under the circumstances. After the injection of half a grain of morphia, in divided doses, he at last became quiet and free from pain, and I then hypnotized him with success, and he remained free from pain for a long time. He, however, returned regularly for treatment every two weeks, and I find that repetition of the operation at about that interval is necessary in these cases. Dr. Van Eeden told me, and I have fully confirmed his observation, that when natural sleep is induced instead of the hypnotic state, the subject is not in touch with the operator, and is therefore insusceptible to suggestion, and no benefit then results from the operation. I have seen natural sleep induced by suggestion several times.

Dr. Forel has stated that it is very inadvisable to hypnotize insane and weak-minded persons in company, as they are very apt to be acted upon by suggestions meant for other patients. I have always found that the more private and serious the procedure is made, the better is the result—at any rate, with English patients.

I have failed to get any improvement in a case of paralysis of the right arm dependent on spinal sclerosis; nor have I been more successful with an old-standing right hemiplegia, with late rigidity, in a young man of twenty-one, dating from an attack of infantile convulsions, and dependent on cerebral lesion.* I gave up a case of congenital chorea, as it was impossible to tell if the patient

* The improvement I have seen result from suggestion in several cases of locomotor ataxy would encourage me to try the treatment in organic cerebro-spinal diseases. Drs. Fontan and Ségard, Professors at the Medical School of Toulon, have published in their 'Elements de Médecine Suggestive' clinical notes of a case of disseminated sclerosis of the cord. The patient improved so much under hypnotic treatment that doubts were thrown on the accuracy of the diagnosis; but the man returned to the hospital the following year and died there of acute tuberculosis. A careful necropsy was made, which revealed very extensive patches of sclerosis, chiefly in the left lateral column, and rendered the improvement somewhat extraordinary. As Bernheim says, there is, no doubt, a great deal of sympathetic and functional disturbance of the neighbouring centres and structures in many forms of cerebro-spinal disease, and it is this element which can be reached by suggestion.

—a boy aged eight, of weak intelligence, but great cunning —were really influenced, or was only pretending. I am unable to say much of its use in epilepsy. In some cases the fits have diminished in number and intensity at first, but they have generally reasserted themselves. Several times, however, I have persuaded the patient to leave off taking bromides, and have generally found that hypnotic suggestion, as long as it is used, will enable the sufferer to dispense with drugs. In cases of bromism this is by no means a small gain.

In the *Zoist* and other mesmeric publications of the last generation one frequently comes across references to the successful treatment of epilepsy by mesmerism, but there is generally a want of scientific accuracy in the accounts of such cases which very much weakens their value.

On *a priori* grounds hypnotism might be expected to exert a powerful influence in epilepsy, and I confess that the rarity with which it has effected cures is a matter of much disappointment to me.

Hypnotism undoubtedly affects the cortical cells, as does epilepsy, and its action on them should be regular and orderly, instead of explosive and destructive. In fact, it might be expected to act as a physiological corrective by controlling irregular nervous discharges, breaking the morbid nerve habit, and conservating the energy which epilepsy dissipates. No doubt hypnotism does act in this manner in most cases of hysterical origin, and in some where no hysteria is present. In long-standing cases, when the disease is hereditary, or when it has a traumatic origin, I should hardly expect, from my experience, to find hypnotism of much value; and, of course, where the disease is traceable to a reflex irritation—*e.g.*, unerupted wisdom-tooth, elongated foreskin, visual defects — this should be put right. It is, however, always justifiable to make a careful trial of hypnotism in cases of epilepsy, for there are many cures now recorded on the best authority. I have never myself cured a case of confirmed

epilepsy, but I have frequently seen it useful in modifying the number and violence of the attacks.

For instance, a young lady, aged twenty-two, was brought to me in 1894. She had developed epileptic fits at the age of puberty, and they were only kept in check by large and continuous doses of bromides. Her mental condition had undergone great impairment, and she was always in a dreamy state. She kept a book in which she made a note of each attack, and altogether she lived in an atmosphere of depression and morbid suggestion. But the symptom which caused most embarrassment, and which cut her off from social life, was the unfortunate delusion which always prevailed when she came out of the fit, that she was going to bed, and she would proceed to undress herself wherever she might be. The fits were always ushered in by an aura starting from her right hand. I found her a good subject, like most epileptics, and responsive to suggestion. I suggested that when she felt the tingling in the hand going up the arm she should be able to prevent the fit by tightly clasping the hands together, and that she should, even if a fit occurred, always come out of it quietly, and know where she was.

The bromides were entirely left off, and the dismal diary was thrown away. The girl improved wonderfully in general and mental health, but the fits still occurred about twice a week. On several occasions she was able to avert them by the pressure as I had suggested, thus establishing an inhibitory influence over the nervous discharge. But the case was too far gone to admit of cure, and we never got beyond a certain point. However, she has never since committed any social solecism in the post-epileptic state, and is able to go a little into society.

In one case I thought cure was effected, for the patient, a City clerk, aged nineteen, went for a year without a fit. Previous to treatment he used to have a bad one about once a week. I believe the young man would have been permanently cured had he taken care of himself and led a rational life. But when he got better he used to drink,

frequent heated music-halls, and dissipate generally, so that no treatment had much chance, and he is now, I believe, a hopeless case.

Dr. Wetterstrand of Stockholm has had considerable success in the treatment of epilepsy by prolonged hypnosis. In some cases he has kept the patient asleep as long as six weeks at a time. He renews the suggestions daily, and the patient eats and performs the usual functions in response to suggestion.

The physiological indications in favour of this treatment are strong. During hypnosis the higher cortical centres in which the nerve storm has its origin are kept in a state of rest, morbid association and periodicity are interrupted, and time given for the weakened and impoverished cortical cells to recuperate and become healthy.

It may here be mentioned that Dr. Auguste Voisin thus treated at the Salpêtrière several cases of periodic attacks of mania occurring in women. He succeeded in curing some of them by the ingenious device of hypnotizing them before the period was expected, and keeping up the hypnosis during the critical time.

I have only had the opportunity of trying this treatment in two cases. Both subjects were hysterical girls, and I found the prolonged sleep beneficial. In one case I kept it up for three, and in the other for four, days.

Dr. Barwise quotes a case in which a lady was quite cured of confirmed epilepsy, and is now the healthy mother of a healthy family. He himself has treated four cases—two of congenital epileptic imbecility which were unaffected, and two the nature of which he does not mention. One is completely cured, and the other has a fit about once in three months, as compared with one or two seizures a week.*

Dr. Barwise has kindly supplied me with the following further particulars about these cases (May, 1891):

'The girl, aged about eighteen, began having fits when menstruation appeared. I saw her in Birmingham about

* *Op. cit.*, p. 20.

a year ago, and she had had no recurrence. Before trying hypnotism I had given her bromides and the usual routine remedies. In the case of the woman patient there was no history of injury, but the attacks were preceded by a feeling of numbness and powerlessness of the left hand.'

Dr. Bérillon treated twenty cases of epilepsy in 1889 and the first half of 1890. He found hypnotism curative in only four cases (quoted on pp. 286-8).

In six other cases the treatment was beneficial in reducing the number of the attacks, diminishing their severity, and improving the general health, the memory and mental condition being notably ameliorated. In the ten other cases the results were negative.

Dr. Outterson Wood tells me he has effected a great improvement, which seems likely to be permanent, in a case of undoubted epilepsy of long standing (reported p. 290).

Drs. Van Renterghem and Van Eeden treated seven cases of epilepsy during 1887-88, and their results are not encouraging. In two cases no effect was produced, and in four only slight or temporary benefit followed the treatment. In a case of hystero-epilepsy in a medical student, brought on apparently by the malpraxis of a travelling magnetizer, they were successful, as already mentioned, in stopping the attacks.

Liébeault considers that epilepsy may frequently be cured by hypnotism when it does not depend on gross organic lesion. He counsels perseverance in the treatment, and cites the case of an unmarried woman, aged thirty-nine, affected with epileptic vertigo from her birth. He continued the treatment assiduously for four years, and at the end of that time the patient was cured, and has continued so.*

The question of the curability of organic disease by any method of treatment is one of much interest, and does not affect hypnotism alone, but all therapeutic methods equally. The answer depends in a great measure on what we mean by cure. If we mean only removal of

* *Op. cit.*, p. 144.

symptoms and arrest of active disease, it is certain that the question is answered in the affirmative every day, for we see patients with obvious signs of phthisis pulmonalis, for example, frequently restored to what may pass for sound health by many forms of treatment. But if we mean restoration of structurally degenerated and altered tissue, I think no physician will have the temerity to maintain that destroyed lung tissue can be restored, or that liver cells spoilt by cirrhosis can be replaced. But there are stages in a disease short of the stage of dissolution of tissue, in which, if healthy action can be set up, we may hope for *restitutio ad integrum:* for example, in the early period of fatty degeneration of the heart, before the muscular fibres have completely lost their character; in the first oncoming of Bright's disease after scarlet fever, before the excreting structure is seriously compromised.

Even when structural alteration has gone so far that restoration of the tissue to its normal quality is impossible, we can often prevent the extension of degenerative changes, and can favour a compensative increase of functional activity in the healthy tissue which remains, *e.g.*, compensative hypertrophy in valvular disease, hypertrophy of the healthy kidney when the other is destroyed. We can also afford relief by removing symptoms and reducing them to their anatomical expression (De Watteville), as we endeavour to do in incurable diseases, such as cancer and tabes dorsalis.

There is a great choice of treatment for the attainment of these various indications, and no sensible medical man feels bound to any one of them, or maintains that it is the only method which can afford relief. Sometimes no treatment is required, and the only indications are to place the patient under the most favourable conditions for the *vis medicatrix naturæ* to act. In other cases a course of hydropathy or massage favours the curative processes, and in others, again, drugs exert a specific effect. Take, for instance, a case of locomotor ataxy. Sometimes the gait may be improved and the pains relieved by suspen-

sion ; by drugs, especially strychnia and antipyrin ; and by hypnotic suggestion. From the way many persons criticise hypnotism and hypnotists, one would suppose that we employed this agent as a panacea in every case. This is exactly the position we want to avoid and intend to keep out of. But we feel that it is a very great point to have at our disposal a method of treatment to which we can have recourse when other remedies have failed.*

I have tried hypnotism in twelve cases of stammering, and in half of these I have found it useful. In two cases, those of schoolboys, complete cure resulted, and in three others there is so much improvement that little inconvenience remains. One of the patients is a barrister, who was debarred from pleading in court by his infirmity. He was only slightly susceptible to hypnotism, but he improved rapidly, and he has recently written to tell me that he has been appointed Recorder of a large town, and fills that important post with satisfaction.

Another recent case is that of a medical student who had repeatedly failed at his *vivâ-voce* examination, not, he said, from want of knowledge, but from a mental confusion which seemed complementary to the physical difficulty of speaking the necessary words. All his attention was required for the mechanical work of articulation, and he could give none to the subject-matter. Probably the stammerer is often handicapped in this way, and I think the remedy is, if possible, to bring about a natural automatism in speaking. The mistake made in many systems is that the attention is more than ever devoted to the weak spot, and morbid self-consciousness, which is such a prominent feature in stammering, is thereby increased.

I always try to impress upon stammerers that clear and easy articulation is a natural act, and should come

* Function depends upon blood-supply in the first place, and it must follow that by influencing the trophic and vaso-motor centres we must affect and control not only psychic processes, but the motor sensory and structural arrangements which form their physical basis. This is practically the position we assume.

spontaneously. It is like walking. If one tries to walk elegantly and picks one's steps, the result is probably a very halting performance, and it is often the same in speaking.

I have observed a great many patients who have been under the treatment of different professors of voice production and elocution. They have been given elaborate exercises, and have probably benefited as long as they carried out the rules laid down, and continued under the eye of the master. But return to the normal conditions of life has generally brought about a relapse. One of the worst cases of stammering I ever heard was that of a young Cambridge man who had for six months been the show pupil of a voice specialist.

These systems attack the periphery instead of the centre, and I am afraid only rarely really cure the patient.

A bad stammer is a terrible handicap in the battle of life, and any means of curing it should be welcomed as a boon. I think hypnotic suggestion is the most hopeful remedy in the case of young adults, and that it will generally succeed in curing children if systematically employed before the habit has become fixed and permanent.

If it is of importance, in some cases, to transfer normal actions from the domain of excessive consciousness to that of subconsciousness, it is no less important, on the other hand, to be able at times to reverse the process, and to bring morbid actions which have become automatic under the direct action of the will. Nail-biting is an example of what I mean. Here the habit has become automatic and unconscious, so the child puts his hands to his mouth and destroys his nails without knowing it, until perhaps he has gnawed them to the quick, and is rendered conscious of his act by the pain. Acting on Bérillon's advice, I have in treating these cases by suggestion made it my aim to bring these unconscious morbid actions into the sphere of consciousness, and establish, as it were, a fence of inhibitory suggestions to protect the threatened part. The child is told that in

future, when he moves his hand to the mouth to bite his nails, he will feel a heaviness in his arm and shoulder and a tingling in the fingers which will continue until he calls his conscious will into play and checks the impulse. An inhibitory centre is thus educated, and I have found this treatment successful in a number of cases not only of nail-biting, but of other bad habits. The same principle is sometimes acted upon in the treatment of drunkards. The patient is told that if he attempts to raise a glass of spirits to his lips his arm will become paralyzed, and he will drop the glass.

I feel perfectly convinced that hypnotic suggestion is the ideal treatment for curing morbid habits in children. If the child is a good subject, as most children are, he can nearly always be cured of stammering by it.

I have tried hypnotism as an aid to treatment in stammering of young children before the habit has become permanent and fixed. In incipient melancholia, and in depression of spirits short of this condition, I have found it of service; but hitherto I have failed to notice much effect from it when the condition was of long standing. On several occasions I have succeeded in removing false ideas, as in the case of a gentleman who was afraid to enter a dark room in consequence of having been frightened by ghost stories when a child. One frequently finds morbid fixed ideas depend upon a suggestion made in early life, and these are well met by a course of counter-suggestion.

I was once consulted as to the case of a young professional man, who was afflicted with bulimia, a form of morbid craving which is, I believe, uncommon. He has periodical attacks of irresistible craving for food, analogous to the desire for alcohol felt by dipsomaniacs. He feels these attacks coming on, and begs his friends to look after him, and take care of his money and jewellery, lest he should pawn them for food. But, in spite of everything, he finds means of raising money, and with it buys food to an enormous amount. This he secretes, and gorges him-

self with until he can eat no more. For instance, on one occasion he bought and devoured within a few hours a quartern loaf, two pounds of cheese, a tinned tongue, a quantity of pastry, a pot of jam, and a large assortment of sweets. The bout is followed by violent sickness and a bilious attack, which lasts for some days. Hypnotism offers the best hope of cure in such a case; but, as illustrating the prejudice against the remedy in some quarters, the patient's friends have persuaded him not to try it, but to live as a voluntary boarder in a lunatic asylum!

Hypnotism introduces one to curious histories. I undertook with some confidence the case of a gentleman, aged fifty, who for three years had suffered from a curious antipathy, apparently half mental and half physical. He was unable to remain in the room with his youngest son, a bright, intelligent boy of twelve, on account of the feeling of restlessness which used to come over him, followed by flushing of the face, noises in the ears, confusion of thought, and palpitation of the heart. He was perfectly sane, held an important financial position, and there was absolutely no cause to account for the sensation. The feeling is confined to this particular boy. At first I found it impossible to influence him sufficiently to master this *idée fixe*, but later on he developed into a fairly good subject.

In December, 1889, the gentleman came to see me, not as a patient, but as escort to a lady who wished to be hypnotized. The lady was nervous, and Mr. X—— offered to let me demonstrate the process on him. To our mutual surprise, he yielded to the soporific influence, and fell into the second stage of hypnotic sleep, after looking at a bright disc held above his eyes for a couple of minutes, and I was at once able to make suggestions combating his delusion. He experienced less discomfort than usual from his son's presence that evening, and there was no difficulty in hypnotizing him subsequently. The morbid idea was of three years' persistence, was steadily increasing in intensity up to the time of his being first hypnotized, and was a cause of serious distress and worry

to him. I had endeavoured to influence him no less than ten times previously with absolutely no effect, and I attribute my ultimate success to the fact that his mind was taken off its guard; and the nervousness and unconscious resistance, which had prevented any hypnotic effect when he came as a patient, were no longer existent when he returned merely as a spectator. Readers of fiction will remember that Dr. Oliver Wendell Holmes learnedly discusses a somewhat similar train of symptoms, upon which he founds his novel, 'A Mortal Antipathy.'

In many forms of genito-urinary troubles I have found suggestion a useful auxiliary in treatment; nor is this to be wondered at when we consider the amount of functional disturbance which is present in these cases. I have cured two very bad cases of prostatic neuralgia, and a most obstinate one of pruritus vulvæ, which rendered the patient's life a burden to her. In many forms of rheumatism the effect of hypnotic treatment is at first sight surprising. It very frequently removes pain, even in chronic rheumatoid arthritis. There is a great deal of neuralgia mixed up with most kinds of rheumatism, and suggestion enables us to meet this, and at the same time to bring about an alteration in the local blood-supply, especially if aided by friction.

Braid was extremely successful in treating these cases, and he used to combine a good deal of manipulation with hypnotism. This manipulation acted in two ways: first, on the part, by helping to break down adhesions, stimulating the muscles, etc.; and secondly, on the central nervous system, by suggestion and direction of the mind to the affected part.

In treating local troubles, it is very advisable to combine Braid's manipulative method with Liébeault's suggestions. In cases of rheumatism I have frequently seen the joint to which this double treatment has been applied quickly relieved from pain, whilst the corresponding one has continued painful until attention was specially directed to it.

I have succeeded on two or three occasions in breaking

down adhesions about rheumatic joints without pain, when the patient would not allow me to touch them in his normal state.

I met with rather a striking case in 1896. The patient was a country practitioner, and had suffered from obstinate rheumatism of the right deltoid muscle for several months. As his practice was a driving one, he found the condition extremely inconvenient as well as painful. He had tried injections of morphia into the substance of the muscle, and had been treated with massage and electricity without benefit. The arm was becoming wasted from disuse, and any movement of the shoulder caused acute pain. He was hypnotizable to the third degree, and I suggested that he should feel no pain when I moved the shoulder, and that there should be no tenderness on pressure. I cautiously swung the arm round, and freely massaged the muscle without his wincing, and in a few moments I told him to open his eyes and try for himself. He found himself much relieved, and the improvement was still more manifest when he came to see me next day. The treatment was repeated on that day and the one following, and he then returned to his practice cured. He was so much impressed by what he had experienced that he took up hypnotism enthusiastically, and began to use it with his patients. He performed two or three minor operations under hypnotic anæsthesia, and relieved many cases of insomnia, neuralgia, and nervous trouble generally. But the village in which he lived was exceptionally antiquated, and the people would have none of this 'new witchcraft.' Dr. S—— found he was looked at askance, and began to lose his practice. Being a family man, and a sensible one, he argued that if his patients didn't want the best treatment he could offer them it was not for him to force it on them to his own ruin. So he wrote a letter to the greatest gossip of the neighbourhood renouncing his advocacy of hypnotism, and undertaking never to use it again in the place. He was received back into the fold of orthodoxy as a sinner who had repented, and he has his reward.

Hypnotism sometimes enables us to understand the nature of a case which has baffled treatment. It threw a flood of light, for instance, on the case of Mrs. B——. This lady came to me suffering from very severe facial neuralgia of more than a year's duration. She was a thoroughly good, well-intentioned woman, who, in addition to devoting herself to a rather exacting husband and seven children, spent several hours a day 'slumming' in a large town. She kept irregular hours, and neglected herself in every possible way, with the result, of course, that she broke down. But she considered it her duty to sacrifice her health, and, in spite of illness, continued to overtax herself. She came up for two weeks' treatment, and I hypnotized her daily. She was only slightly susceptible, but quite sufficiently so for our purpose. She told her husband after two or three days that though she was getting better this was due to the change and rest, and that she was not hypnotized. He very sensibly told me this, and enabled me to make a necessary change in my methods. I hypnotized her as usual, and asked how she felt. She replied that she was comfortable, and that the pain was better. I then told her she couldn't open her eyes, and she tried in vain to do so. Then I assured her that she was under hypnotic influence, that she would be cured, and that she would not be able to open her eyes until the pain had quite gone.

For twenty minutes it was a duel between us, for all the time she was trying to open her eyes, while I was suggesting she couldn't until the pain was cured. Gradually she acknowledged that it was getting better, and at last she said it was gone, and opened her eyes. She had no more pain, and returned to the country quite well and strong. She remained well for six months, though she again systematically neglected all the rules of health; and then I hear she had another breakdown, accompanied by severe sciatica.

This lady was one of those who hug their infirmities and call it 'bearing their cross.' She was quite sulky

when she had to give up her neuralgia, though, of course, she would not admit it. It had become a part of her personality. Sometimes one is told by such patients that they wouldn't know themselves without their disease. Many people allow themselves to fall into a state of invalidism because it is, they think, interesting, and appeals to their friends' sympathies; and others take up the rôle because they find it is one they can fill gracefully after perhaps having failed in other walks of life.

The subconscious mind is a strange thing, and plays curious pranks with our health and thoughts. It is not reached by drugs, but by psychical influences, and I believe hypnotism to be the best and most philosophical way of employing these.

In various small surgical procedures, such as lancing whitlows, opening abscesses, etc., I have found hypnotism a useful anæsthetic; and it is evident that in certain operations in which chloroform is inadmissible, either from the condition of the patient or from the locality of the operation, hypnotism may be a valuable substitute.*

Creed finds hypnotism very useful to relieve pain and prevent spasm after fractures and other accidents. He has trained some of his patients so that they can throw themselves into a state of hypnotic anæsthesia by using a prearranged signal. For instance, a gentleman let a quantity of 'Chatterton's Compound,' a substance more destructive than molten sealing-wax, fall on his hand. He immediately put the index-finger of his left hand to his mouth, which was the signal agreed upon, and a state of analgesia at once followed. The patient did not lose consciousness or become affected in any way beyond that he felt no pain. Recovery from this severe injury was rapid and painless. In dressing surgical wounds Creed finds he can induce local anæsthesia by suggestion, without other hypnotic effect, so that the patient goes on talk-

* It has been used in this way at the Paris hospitals, and notably in one case of ovariotomy at the Hôtel Dieu.

ing rationally all the time (*loc. cit.*, p. 7). I have also seen several cases of this kind.

It may be objected that it is dangerous to suppress pain, which is Nature's danger-signal to call attention to the injured organ. This is only true to a limited extent. The amount of pain is generally far in excess of such requirement, and its alleviation is one of the practitioner's most urgent functions. Fortunate is the patient who can have this effected without opiates or other anodyne drugs.

Creed vaunts hypnotism as often specific in treating vomiting, and says that no good hypnotic subject need suffer from sea-sickness.*

I have tried the effect of suggestion on five or six patients who were about to make long sea-voyages. In one of these the effect was very striking, for, though the sea was rough, the lady for the first time in her life was free from sickness. In two other cases there was great improvement compared with previous experiences. In every case the result justified the trial of the remedy. Liébeault, Osgood, Gorodichize, and other physicians have also used hypnotic suggestion successfully against *mal de mer* (*Revue de l'Hypnotisme*, 1896). Osgood reports four cases of chronic eczema which he cured by suggestion, and one remarkable case of chronic dermatitis of exceptional severity after frost-bite.

The casual and careless application of hypnotic suggestion will be no test of its value, and handing it over to unscientific persons will certainly end in disaster.

* The following extracts from a letter from a highly-respected country practitioner in New Zealand are, I think, worthy of consideration: 'In February and March last I made a trip over to study hypnotic suggestion in Sydney, under Dr. Creed, who has taken the matter in hand after due inquiry. I have certainly been greatly astonished at the results obtained in my cases. . . . I have never yet touched a case which I have not enormously benefited, far and away more than I could do by ordinary treatment. . . . I very much regret that I had not taken the subject up years ago. But, like the rest of our profession, I was prone to believe there was a good deal of low-down charlatanism about it. After reading Dr. Creed's address to the N.S.W. branch of the B.M.A., of which he has been twice president, I communicated with him, and went across to see him, and I have been easily able to prove personally nearly all I saw there.'

If medical men will employ the Nancy method of treatment in their ordinary practice, they will find it a very useful auxiliary in many trying, painful, and tedious cases.

By expressing this opinion I have aroused some opposition; for there are those who think that, besides damaging the patient's health, the practice of hypnotism would ruin the doctor's pocket and reputation, since he might become the prey of designing adventurers and the victim of all kinds of charges and blackmail. I don't suppose that the most enthusiastic hypnotist would advise the practitioner to hypnotize his patients recklessly and promiscuously; on the contrary, the more experienced he is, the greater caution will he exercise. But probably every medical man has many patients who would very much prefer twenty minutes' somnolence in an easy-chair as treatment for neuralgia to a course of medicine, and others on whom the resources of ordinary treatment have been employed in vain.

It is well to understand that the Nancy method of hypnotization acts on the central nervous system as a brain calmative, and that its object is the production of a state analogous to natural sleep by imitation of natural processes, and is thus a wooing of repose. The condition obtained is characterized by increased suggestibility, and it is through this the treatment works. The method adopted by Charcot and his imitators to obtain catalepsy by causing a violent and sudden sensory impression—by sounding a gong or flashing a bright light—acts in a totally different way, and induces a state analogous to that produced in waking moments by sudden fright or shock, which paralyze and transfix with terror. It is the difference in method shown by two nurses, one of whom quiets her charge by gentle persuasion, while the other prevents her from crying by threats of the policeman. Both children are kept quiet, but how different will be the after-effect of the two methods!

A visit to some of the Paris hospitals will afford justification for the assertion which is sometimes made, that

abuses have not been confined solely to non-medical operators, and I am in agreement with a French correspondent who writes:* 'I consider that every hypnotist commits a very grave fault when he provokes post-hypnotic phenomena which have no bearing on the treatment of the case. The production of pains or paralyses which do not exist, and of hallucinations, etc., may determine brain troubles, and lead to accidents.' The temptation to experiment is sometimes great, but it should never be yielded to except with the full consent of the subject, and for a definite scientific object. The old experiments have been repeated *ad nauseam*, and who is now the wiser for seeing a 15-stone operator stand on the outstretched body of a cataleptic subject, or what can be learned from seeing a victim eat tallow candles under the impression they are sweetmeats? When experiments are made, it is important not to repeat them too often, and to be careful always to remove any suggested hallucination before the subject goes out into the world. The much-quoted case of Krafft-Ebing's illustrates very clearly the dangers of hypnotism when the state is induced constantly and wantonly in a morbid and hysterical subject. While in a hospital at Pesth, before she came into Krafft-Ebing's hands, she was constantly being hypnotized, not only by the physicians, but by all sorts of people, simply for amusement; and in the hypnotic state most absurd and trying hallucinations were generally suggested to her—'that she was a dog, that she was intoxicated, that there was a snake on her dress,' etc. What wonder that she ran away from an institution where such things were allowed, and that when Krafft-Ebing saw her first, he found her confused, absent, and with her mind full of delusions and misconceptions! This poor girl was one of a family in which suicide, hysteria, and madness were rampant, and it would be hard to find a surer plan than that adopted of developing all the diseased mental traits latent in her constitution.

* Dr. David, of Sigean (Aude).

Professor Krafft-Ebing has embodied in his book the experiments which he continued to make on this subject, but they were conducted with great care, and led to the elucidation of many instructive points. He says: 'No detrimental effect upon her disease was ever observed as a result of hypnosis when proper precautionary suggestions were made.' This patient was so susceptible to suggestion that stigmata could be evoked, and on one occasion so severe an injury resulted from the suggestion of a severe burn on her arm—the blade of a pair of scissors being held against the skin, and the suggestion made that it was red-hot—that the wound took several weeks to heal.

It has been asserted that there is danger of persons who have been hypnotized becoming subject to attacks of spontaneous somnambulism, and of their being reduced to a condition of dangerous over-credulity. I can well believe that if the method adopted is defective, there is some justification for these fears. If, for instance, a person is told that he is to fall into a state of catalepsy on hearing a gong, the result might be embarrassing when the dinner-gong sounded (see note, pp. 56, 57).*

Again, suppose a patient has been frequently hypnotized by being made to regard the rotating mirror. Certain advertisements at our railway-stations bear a considerable resemblance to this instrument, and it is possible that a sensitive subject might be involuntarily hypnotized through staring at them. Fortunately, such mishaps need never occur. The method used should be of a nature not likely to be spontaneously reproduced, and

* Men, like the lower animals, are creatures of habit, and association of ideas plays a leading part in our words and actions. If the association is artificially strengthened by hypnotic suggestion, it may be of overmastering cogency. We all know the story of the circus horse which was borrowed for use as a charger. Everything went well until the end of the review, when 'God save the Queen' was played. At the first bar the animal reared on its hind-legs, at the second sat down on its haunches, and at the third rolled over on his back. He had been trained to those actions, and they were evoked by the accustomed stimulus.

the patient should be told that he is not to feel the least inclination to hypnotic sleep except under certain circumstances, and with his own full consent. So powerful is the effect of suggestion, that the subject thus protected will probably be safer against hypnotic wiles than a person who has never been hypnotized. It has often happened that when the patient has been warned against allowing himself to be hypnotized, the very operator who has made the deterrent suggestion has for a time been unable to influence him.

There is another objection urged against hypnotic treatment, namely, that its effects are temporary, and that when a relapse occurs hypnotism will not again prove even palliative. The exact reverse is the truth. A patient who has been once relieved by hypnotic treatment is from that very cause a particularly good subject for future treatment by the same means. In diseases where the influence of hypnotism can only be temporary and palliative, as in locomotor ataxy and cancer, it will be found to relieve the pains more quickly and surely after six months than it did at first.

It is not easy to understand what foundation there is for many statements made about hypnotism. Most of these stories probably date from the time when mesmerism was extensively practised by ignorant and credulous persons, and others are perhaps founded on the experiences of professional magnetizers who have not been careful as to their method nor too scrupulous in their aims. I have on two or three occasions seen the induction of hypnotism for medical purposes actuate an attack in an epileptic subject, and I have also on more than one occasion seen it threaten to develop an access of hysteria in a subject in whom that neurosis was latent. But in nearly all cases it is easy to control any untoward symptoms by calming suggestions, or, if these fail, to awake the patient and discontinue further proceedings for the time. I think there is no doubt but that hypnotism determines the manifestation of latent emotional states—in the

same way as chloroform—and this is a reason for insisting on its very careful handling. I have only seen one class of willing patients in whom hypnotism seemed rather to produce an aggravation of the symptoms—cases of what Dr. Whittle calls congestive neurasthenia. In the last two cases of the kind which came under my observation, I began by adopting the course recommended by Dr. Whittle, and applied three leeches behind the ears to relieve the urgent congestion. This procedure greatly relieved the head symptoms, and I then induced hypnosis with great facility and considerable advantage. The patient should feel refreshed and invigorated after the operation, and if this result is not observed, but lassitude should prevail in spite of suggestions to the contrary, I think it may be taken as a sign that the treatment is counter-indicated. I have only met with one case of the kind in my own practice, but I have heard of a few others.

My friend, Surgeon-Major Neilson (Canadian regiment of artillery), tells me that the thing which first made him investigate hypnotism was seeing the effect of the treatment on a bugler belonging to his regiment, who was in hospital and given up as a hopeless case of phthisis pulmonalis. He hypnotized the man, and suggested quiet sleep, freedom from cough, and good appetite. The patient was only affected to the second degree, but the suggestions immediately began to tell: the exhausting, ineffectual cough diminished, the appetite improved, and the man slept well. In six weeks he was able to leave the hospital and return to duty. The man was never influenced beyond the second degree. One would, of course, like to have the physical signs and points of diagnosis thoroughly described in such a case, as I am sure Dr. Neilson would not maintain that the processes set in motion by hypnotic suggestion can restore broken-down lung-tissue.*

* The following extracts from a letter recently received from Dr. Neilson will perhaps be of interest to the reader. Writing from Kingston, Ontario, he says : ' Military practice offers but few opportunities of practising hypnotism, but so far I have applied it in about

Dr. Myers (*Practitioner*, vol. i., 1890, p. 201) mentions a case of acute pneumonia he saw treated by Bernheim in the hospital at Nancy. The man had the physical signs of congestion of the bases of the lungs, and was in a state of high fever and delirium. He at first refused to be hypnotized, but eventually gave his consent, and Dr. Bernheim sent him to sleep for five hours. The man awoke refreshed and free from pain and delirium, but the physical signs remained unaltered. A medical friend of mine, suffering from pleurisy and high fever and much pain, induced a colleague to hypnotize him, with the result that he experienced almost immediate relief, and, though the disease ran its usual course, there was but little subsequent pain.

The naïveté of some people who use things without knowing their nature reminds one of Molière's bourgeois gentleman, who was surprised to find that he had been talking prose all his life. Among the medical men who have honoured me by coming to see some of my cases is a gentleman who seemed much struck at seeing the method I adopted with a rather refractory subject. I held his hand and stroked his forehead, while at the same time suggesting the symptoms of sleep. The gentleman told me afterwards the reason why he was so interested. It appears that he had a few months previously been in attendance on a very severe and protracted case of delirium tremens. The patient could get no sleep, and the doctor was afraid of death from exhaustion. On the third evening he resolved to make a strong effort to produce sleep, and, if necessary, to sit up all night with the patient. He told the man that he would not leave him until he slept, and, sitting down by the bedside, he took

100 cases. . . . In eight or ten with brilliant success, in thirty or forty with fair success, and in the remainder with little or no result. The best results were obtained in cases of female derangements, muscular rheumatism, functional dyspepsia, constipation, insomnia, chronic pulmonary complaints, and dipsomania. Of the last-named I have treated five cases and have obtained two cures, *i.e.*, the patients have remained total abstainers, in one case twenty and in the other fourteen months without any sign of a relapse.'

his hand in one of his own, and with the other gently stroked the forehead. At the same time he talked quietly and reassuringly to him. In less than half an hour he was rewarded by seeing the restlessness entirely cease and the man drop off into a quiet sleep. That sleep, the doctor told me, lasted fourteen hours, and the patient awoke out of it weak, but cured. Manipulation about the head has in many persons a most soporific effect, and several persons have told me that they always become drowsy under their barbers' hands.

It is said by Liébeault, on the authority of several writers,* that persons in the hypnotic state, whether it be induced spontaneously or by external means, are able to ingest without evil results much larger doses of poisons than can be taken in the normal condition, and that the bites of venomous serpents are very much less likely to prove fatal than in the waking state.†

The action of hypnotism here is probably similar to that exerted by chloral in the treatment of tetanus, and of large quantities of alcohol as a remedy for snake-bites. The excitability of the nerve-centres is controlled, and excessive and exhausting discharge prevented, until the poison has been eliminated. I should imagine that hypnotic treatment is likely to prove useful in the treatment of tetanus and other spasmodic diseases depending on increased reflex excitability of the brain or spinal cord —not, be it understood, to the neglect of other treatment, but as an auxiliary.

To show what suggestion may do, I will cite the case of a medical friend who asked me to hypnotize him and make suggestions about retaining his water. He had an organic stricture and felt the greatest dread of a catheter.

* *Op. cit.*, p. 222.

† Several medical men who were present at a recent performance assure me that they saw somnambulic subjects swallow as much as 80 grains of quinine in one dose, and that they watched for effects and found none. The same public performer made his unfortunate subjects drink large and almost poisonous quantities of paraffin oil, kerosene, and other nauseous compounds without producing any result.

I found him hypnotizable to the second degree, and I made suggestions that he should be able to retain his water for four or five hours during the day and all night. After three or four sittings he assured me that, instead of having a call nearly every hour day and night, he is now able to go as long as most people. In this case I doubt if the treatment has not done more harm than good, for by relieving the symptoms it has enabled him to postpone the surgical interference which is urgently called for. I have frequently been able in the same way to relieve the dysuria of patients suffering from Bright's disease or diabetes, and sometimes even that due to prostatic enlargement.

Dr. Kingsbury, of Blackpool, has reported in the *British Medical Journal* and in his book a remarkable case of painless and rapid delivery in the hypnotic state. The patient, a young girl under fifteen, was hypnotized several times previous to the confinement, and was most deeply influenced.* Dr. Milne Bramwell has brought the surgical use of hypnotism prominently before the profession, and operations were frequently performed at Leeds with him as hypnotic anæsthetist. I need hardly remind the reader that Dr. Esdaile, Presidency Surgeon at Calcutta, performed many capital operations under mesmeric anæsthesia forty years ago.

Dr. Milne Bramwell excited great interest by showing the profession at Leeds how easy it was for him to hypnotize subjects at a distance by telegram or letter. One patient went into a deep trance immediately she handed the dentist a note, and in this state had several teeth painlessly extracted. Suggestion, of course, is the explanation of this result. On some occasions where it

* Dr. Marie Dobrovolsky has described in the *Revue de l'Hypnotisme* for March, 1891, a series of eight confinements in which she has employed hypnotic suggestion. The pains were either greatly diminished or abolished in all the cases, and that without interfering with the uterine contractions. In several of the cases only a slight hypnotic sleep was induced. In every instance the patient was previously hypnotized several times preparatory to the lying-in.

has been necessary to break off the treatment prematurely, or where it has been advisable to continue it over long periods of time, I have found the following plan very efficacious: The patient is given a paper on which are drawn several lines and figures, and he is told that once a week, or as often as is necessary, he is to lie down in some place where he can be quiet, and hold the paper in his hand at a convenient distance from his eyes. After looking at it a few seconds with the desire and expectation of sleep, he will pass into the stage of hypnosis he ordinarily assumes, and in that state the memory of the suggestions previously made will recur to his mind, and he will feel them producing their usual effect. It is important to remember to tell the patient that this course is only to be adopted at the prescribed times, and that, in fact, it is a medical prescription.* A paper is not always necessary: a patient whom I am in the habit of sometimes hypnotizing by gentle stroking of his forehead tells me that he now frequently sends himself to sleep at night by imitating on himself this simple process.

I have been successful in a good many cases of neurasthenia brought on from overwork, anxiety, or dissipation, and also in the depressed nervous condition sometimes seen to persist after typhoid and other fevers.

Dr. Clifford Allbutt says ('Gulstonian Lectures,' 1884), the neurasthenic patient has no reserve of energy. He

* The following extract from a letter received from a patient who was for some months under my treatment explains the working of this method. The gentleman was a dipsomaniac of the very worst type, and after keeping sober for seven months he left England and soon relapsed. He then went to stay in a retreat where no treatment was employed but enforced abstention; and as he told me that he found it much more difficult to abstain without hypnotism than with it, I adopted this plan. 'Doing as you suggested,' he writes. 'I made the first attempt last week, and it was completely successful. I went off at once, bearing in mind that I was to awake in ten minutes. I took the time and found that I awoke to the minute. All your suggestions came back and repeated themselves, as it were, frequently. I could quite have believed that you were there making them, and they were spoken in your voice.' Surgeon-Major Neilson first caused me to try this method. He practised it successfully in the case of a soldier, whom he cured of confirmed drunkenness of twenty years' standing.

has exhausted it perhaps in work, but frequently in dissipation, and it has never reaccumulated. He lives, as it were, from hand to mouth on the day's supply, and a precarious existence it is. In such cases sleeplessness is a very prominent symptom, and even when sleep is obtained it will generally be found that it is of an unrefreshing character, so that the patient wakes up saying he is more tired than when he went to bed. Theoretically, hypnotism ought to work wonders in these cases, and as a matter of fact the treatment is often most successful in them.

I have twice been called in to see what hypnotism could do to procure euthanasia. In one case the medical man in attendance was afraid to give narcotics on account of the state of the heart, and in the other the patient begged that nothing should be given to her to make her unconscious. Hypnotism soothed their last hours to a remarkable extent, and afforded the greatest comfort to the relatives. It should certainly be thought of in cases where the patient's last hours are embittered by excessive irritability and restlessness and there are reasons against giving drugs.

Dr. Woods (*loc. cit.*) relates his experience, and gives most gratifying testimony as to his success in over 200 cases which he had treated by suggestion. These comprise many very bad cases of chronic alcoholism, mental disease—chiefly melancholia with delusions—headache, neuralgia, lumbago, gout, dyspepsia, epilepsy, chorea, and writer's cramp. His results correspond with those obtained by other observers. Dr. Woods states that he is often successful in curing his patients by suggestion alone without hypnosis.

Such detailed experience as that of Dr. Woods is most convincing and valuable. It is corroborated by medical men all over the world. The latest pronouncement on the subject I have seen is that of the Hon. Dr. Creed, of Sydney, New South Wales, who uses hypnotism extensively in his practice. He does not claim it as a panacea, but considers it as of great service in many

cases of every-day occurrence. For instance, he says, when a good hypnotic subject has a bone fractured, hypnotism will not set the limb or directly repair the injury, but it may assist recovery by preventing pain and muscular spasm, and giving sleep and appetite. In a case of pleurisy he so completely removed the pain by suggestion that only the most careful physical examination and the continuance of an abnormally high temperature convinced him that it was actual and acute pleurisy.

He relates success in many very bad cases of chronic alcoholism and the morphia habit. He considers it specific in insomnia, and most efficacious in asthma and in heart symptoms, even when dependent on organic disease. He has seen it helpful in relieving the severity of epilepsy, and curative in several severe cases of chorea.

He has used it in several cases of gastric ulcer, and speaks with enthusiasm of the results he has obtained. He finds, he says, the stomach can, if pain be prevented, digest a fair quantity of nourishing food without difficulty; and the cessation of the state of semi-starvation in which the patient has lived soon brings about such an improvement in nutrition that the ulcers heal. He finds it very successful in curing vomiting, and even in preventing sea-sickness. He says: 'For obstinate vomiting I believe that in suggestion we possess a remedy which will prove effective when all ordinary ones have been tried and failed.' He also advocates hypnotism as the best remedy for megrim, incontinence of urine, and many forms of neuralgia; and affirms that no good hypnotic subject need suffer from sea-sickness.

Dr. Van Renterghem gets more cases of neurasthenia than of any other disease in his clinique at Amsterdam, and reports having treated 118 cases during the four years from 1893 to 1897. Of these eighty-six were men and thirty-two women. He states that thirty-one were cured and sixty-one were much benefited by hypnotic treatment. A very good showing in such an intractable disease. Neurasthenia, as Dr. Savile and other writers

show, depends upon so many causes that it does not do to treat every patient alike. *Tolle causam* is as important an axiom here as in any class of case. If the condition depend on central nervous causes, such as mental shock, overwork, excessive venery, or if it follows debilitating disease, like typhoid fever or influenza, I believe hypnotism is the best treatment, and that it alone will cure the patient *cito et jucunde*. If the neurasthenia is the result of mal-assimilation and fermentation of food, suggestion will help to promote eupepsia, and whatever the cause, it will, if the patient is hypnotizable, relieve the mental gloom which weighs him down, and thus hasten his recovery. Neurasthenic patients are apt to be difficult. Being self-centred and of low vitality, it is not easy to gain their attention ; and they are, as we all know, inclined to be sceptical, hopeless and averse to giving treatment a fair trial. They constitute a large proportion of those patients who enter the physician's consulting-room with the announcement that he is the thirtieth or fortieth doctor they have consulted, and that no one can do them any good. Success in the treatment of such cases depends a great deal on the doctor being able to inspire confidence and to employ suggestion whether with or without hypnotism.

The following case presents many points of interest. In 1893 an American working man came to me with a note from a well-known omniscient editor, and this was his story : He was thirty years of age, and had been for ten years a labourer in the shipyards at Boston. He had led a dissipated life, but was very strong and well until he had a bad attack of influenza in 1892. This left him so weak that he could not go back to heavy work, and if he attempted to stoop there was severe pain in the lumbar muscles. Ordinary remedies did not set him on his legs, so he studied his case for himself, and found in a medical work on influenza in the public library in Boston laudatory references to hypnotism in the treatment of the sequelæ of the disease, and the statement that the system

was practised at Nancy in France. Without further inquiry he sold his effects, and with the money took a steerage passage to Havre. Thence he went to Paris, where he found he had spent all his money and was still a long way from his goal. He went to the American Consul, who advised him to come to London, and gave him money for his fare. Arriving in London, he wrote to the omniscient gentleman referred to, who is as well known in America as in England, and he referred him to me. I hypnotized him, and he became at once somnambulic. I let him sleep for several hours, and suggested increased vitality and freedom from pain in the back. These suggestions, combined with movements and massage, were repeated five or six times during the next ten days, and then the patient announced himself as cured. He set off to look for work, and found it as a dock labourer. He came to tell me that he could work all day, carrying heavier loads than most of his mates; and that he was saving up his wages so as to get back as soon as possible to his own country.

No doubt the trouble and expense this patient was put to helped to get him into a suitable frame of mind for cure from the treatment he had set his heart upon. If he had only known it, there were at the time at least two able physicians practising hypnotism in Boston, and it would be interesting to know if the treatment would have been equally successful if he had found it at his door. I think it would, for he was a good subject, and one was able to drive suggestion well home. This strong, self-sufficient working man possessed the spirit of the pilgrims of the Middle Ages, and no doubt the grotto at Lourdes claims many such votaries, who return from a pilgrimage there cured from their diseases.

The profession is indebted to Dr. Milne Bramwell for much information concerning the therapeutic uses of hypnotism. He has frequently demonstrated its availability as an anæsthetic in surgery, and he has brought an exhaustless fund of patience to bear on the most obstinate

cases. He has described a case of pruritis vulvæ which had resisted all attempts at hypnotization for sixty-seven times, but he succeeded in inducing somnambulism the sixty-eighth time, and the patient was cured!

He showed at Leeds a case of aphemia with paresis of the legs, which had lasted for three years, which he had cured in a few days by hypnotism: a case of hyperidrosis existent in a girl since infancy, with a patch of skin on the left wrist so affected that the perspiration was continually dripping from it to the ground. She was cured almost immediately. A case of intercostal neuralgia in a boy was cured in three sittings. In four cases of Ménière's disease he found great improvement was brought about in the hearing, and the vertigo was almost entirely removed. Dr. Bramwell tells me that he has never seen any harm done by judicious employment of hypnotism, and this statement coming from him must be acknowledged to carry great weight.

A somewhat similar case of hyperidrosis is reported by Dr. A. Charpentier.* The patient, a young man of twenty, had suffered from excessive sweating of the hands for five years, apparently dating from a mental shock. Intermittent to begin with, it had for two years been continuous, and was so abundant that when the hands were held down the perspiration flowed from the finger-tips as from a filter. Many forms of treatment had been tried, including astringents, ergotine, atropine, scarification, electricity, but without success, and at last Dr. Charpentier bethought himself of hypnotism. After some difficulty the patient became a good subject and completely somnambulic. Improvement immediately resulted from suggestions directed to the central origin of the trouble, and the young man was shown cured at a meeting of the French Société d'Hypnologie et de Psychologie.

So far I have only attempted to treat one case of hyperidrosis by suggestion. The patient is a young lady who

* *Revue de l'Hypnotisme*, January, 1900.

came under treatment in 1899 for severe and almost continuous frontal headache. This was speedily cured by suggestion, though it had for a long time resisted all the usual remedies, and she was only slightly hypnotizable. She then told me of her other trouble—excessive perspiration of the brows and nose, brought on especially by any mental emotion, and a source of endless distress and annoyance to her.

Probably a profound degree of hypnosis is necessary before suggestion has sufficient influence over the central nervous system to control such a local condition. I never could get more than a slight torpor and drowsiness with this patient, and the condition underwent no change.

The medical world is familiar with instances where a treatment which has been highly praised in some quarters has failed to produce good results when tried elsewhere. Apostoli's method of applying electricity in uterine fibroids, and Charcot's suspension treatment for locomotor ataxy, are cases in point. Neglect of apparently trivial technicalities may explain some of these discrepancies.

Practitioners of the Nancy school all over the world are agreed as to the efficacy of hypnotic suggestion, and of the absolute importance of observing points of detail. Bernheim asserts, and Forel agrees with him, that no one is entitled to speak with authority on the subject until he succeeds in hypnotizing at least 80 per cent. of the hospital patients on whom he tries the treatment. Hypnotic suggestion is a psychical treatment, and to use it successfully demands tact, judgment, medical knowledge, and knowledge of one's patient, or, in the words of Dr. Felkin, a firm will, unlimited patience, and a calm temperament.

NOTE —The experience of a scientific and critical friend, Dr. B——, whom I have frequently hypnotized, is interesting. He is a healthy man of forty-five, of dark complexion and lymphatic temperament, somewhat hypochondriacal, and a clever and successful practitioner. He is a good subject, and is sometimes affected to the third, and sometimes only to the first, degree of hypnosis. For Liébeault's 'stages,' see p. 51.

When told that he cannot open his eyes he makes no attempt to do so unless strongly urged to try, when he proceeds in the ineffectual manner already described. With much effort he is generally able to move his arm, in spite of my prohibition, but the force employed is evidently entirely out of proportion to the result achieved. In the hypnotic state he feels absolutely tranquil and at rest, and when exhorted to exert himself he reflects : 'Of course I can do any of these things if I only try, but I am not going to disturb myself by trying.' When told that he will open his eyes and be wide awake when I count fifteen, he makes up his mind not to comply, and yet when I reach fifteen he cannot help becoming wide awake. After removing a real pain, such as occipital neuralgia, I have frequently, in the same subject, induced a pain localized by suggestion—*e.g.*, in the eye or forefinger. Dr. B—— frequently feels a sensation of numbness, heaviness, and 'pins and needles' in a limb for some minutes after I have told him it is fixed and immovable. It is interesting to note that having been frequently hypnotized does not prevent him from successfully operating on others ; and he is beginning to use the Nancy method in his practice. In this case and all others I find the patient's co-operation is absolutely necessary to success, and I have always failed to produce any effect upon him and others when I have either asked them to resist, or when there has been some disturbing emotional element present. This is an important fact in face of the statement sometimes advanced—that after being hypnotized the patient is unable to resist subsequent attempts. I speak here only of medical hypnotism. Though I have failed to find the inhalation of chloroform of much use in inducing hypnosis in the four or five intractable cases where I have tried it, such has not been the experience of some other observers. Dr. Abdon Sanchez Herrero, Professor of Clinical Medicine in the University of Valladolid, contributed to the congress a paper on 'Forced Hypnotization' (*Comptes Rendus*, p. 212). He, following up the experiments of Dr. Rifat, of Salonica, found that there is a short period during the inhalation of chloroform when the subject is as open to outside suggestion as in somnambulism, and this stage is, he says, at the end of the period of nervous excitement, and before that of delirium—a space of very short duration, sometimes only of a few seconds. Dr. Herrero experimented on six patients, whom he had previously found to be absolutely insusceptible to hypnotism after repeated and long-continued attempts. He failed in the first two cases owing, as he thinks, to allowing the favourable moment to pass ; but in the other four he was successful in hitting upon the exact period of 'suggestibility.' To the first he suggested ready susceptibility to ordinary hypnotism the following day, and as a result the hitherto intractable patient was hypnotized by a few minutes' simple fixation of the eyes the next morning. He suggested to the other three patients daily increasing susceptibility to the action of chloroform, and finally the production of anæsthesia and unconsciousness without the drug. In each case he was successful within a week in reducing the quantity of chloroform to the vanishing-point, and in inducing what was practically hypnotic somnambulism by simple suggestion. Dr. Herrero has continued his researches, and feels himself justified in asserting that in chloroform we have an aid to hypnosis which will enable us to hypnotize the most intractable cases, and he proposes it as an alternative to the terribly fatiguing and somewhat repulsive method pursued by Dr. A. Voisin, at the Salpêtrière, in cases of insanity. This paper throws a light on the induction of anæsthesia in

Mr. Brain's case (quoted p. 10), and also on Bernheim's assertion that he finds the action of chloroform greatly reinforced by suggestions made whilst administering the anæsthetic.

Herrero, Von Schrenk-Notzing, Wetterstrand, and other authorities have made considerable use of chloroform for the purpose of quieting nervous excitement and breaking off the life of relation, and so favouring the induction of hypnosis. They express themselves as well pleased with their results. Dr. Van Velsen, of Brussels, tells me that he succeeded in hypnotizing a friend after giving him 10 grains of chloral whom he never could influence before, though he had made many attempts; subsequently the patient was susceptible without chloral, and became a somnambulist.

Dr. Barwise says: 'I have had no difficulty in hypnotizing patients taking bromide of potassium or chloral hydrate, and from some observations I made a year or two ago upon the action of cannabis indica in the treatment of sick headache, I was led to the conclusion that this drug predisposed to hypnosis, and a recent experience has removed all doubt of it' (*op. cit.*, p. 7).

I should here like to add a word of caution against regarding hypnotism as a panacea in every case of drunkenness. I am thoroughly convinced of the value of hypnotic suggestion as *an aid* to moral reform, and look forward to a time when it will be used in all retreats for inebriates and other reformative institutions; but I recognise its limits, and I know that its indiscriminate employment will only bring disappointment to the patients and discredit to the system.

When we consider that hypnotism simply intensifies to a notable extent the influence of suggestion on the bodily functions and mental characteristics, we see how its curative scope is necessarily limited by pathological and other conditions, and how illogical it is to expect miracles in the way of moral reformation from it alone. Granted the patient has preserved some degree of self-control, and has a strong desire to be cured, it is possible that success may result from the use of hypnotic suggestion even when the surroundings continue unsatisfactory. Under such circumstances I know that publicans have been cured without leaving their business, and soldiers without quitting their regiment; but I regard these cases as exceptional, and in long-standing or inherited dipsomania removal from temptation is an essential condition of success.

It is important to bear in mind how drunkenness varies in degree and kind. Between the man who drinks to excess when occasion offers, and who cannot resist the solicitations of friends, and the dipsomaniac, there is a great difference. Though the ordinary drunkard may become a dipsomaniac, this is not usually the case. The drunkard is mad because he drinks; the dipsomaniac drinks because he is mad. Dipsomania is a form of impulsive insanity, which is nearly always inherited, and which manifests itself by uncontrollable fits, during which the patient is obviously insane. Dr. Ball, speaking of this disease, says: 'The prognosis is absolutely hopeless, especially when it depends on heredity, and is not due to acquired habit. Such patients are never cured, though the methods of treatment are as varied as they are numerous. . . . If there is any chance of safety for them, it lies only in their being placed under restraint for a prolonged period—I may say for an indefinitely prolonged period' (*op. cit.*, p. 797).

I have treated during the last twelve years nearly 200 cases of chronic alcoholism, and have found hypnotic suggestion has proved completely curative in about a third of these. This is a good result, considering that in no case was the patient confined in a retreat or kept away from his home or business for longer than a month. I only stipulated that for a specified time he must be under responsible supervision, and must lead a healthy and rational life. One generally found self-control was rapidly regained, and it became safe to gradually give him more liberty. The immense gain of this treatment in suitable cases over that of confining patients in a retreat for twelve months—the least time the advocates of this system recommend—is apparent. Not only does the patient keep in touch with his family and business, but he is saved the demoralizing effects of a loafing and idle life. I know inebriate retreats are necessary, and many of them are admirably managed, but association with other drunkards cannot be beneficial, and it is impossible to

find rational employment for all the inmates of a retreat for the better classes.* I should like to see every drunkard given the chance of speedy and pleasant cure by hypnotic suggestion under favourable conditions. If it failed, I should consign him to an agricultural colony for inebriates conducted on somewhat similar lines to those adopted at the excellent institution for epileptics at Chalfont. Work, discipline, and hygienic surroundings are the remedies for chronic alcoholism, as idleness, laxity of aim and principle, and unhealthy surroundings, are its principle causes.

I have embodied my views on this subject in a paper I read at the annual meeting of the British Medical Association at Nottingham in 1891, which is published in enlarged form by Messrs. Churchill; and I herewith (p. 210) reproduce a table from a paper I read at the International Congress on Psychology held at Munich in 1896.

Among my successful cases are certainly seven of real dipsomania. In nearly all cases I have seen partial or temporary success, and in many instances where there was relapse, cure would, I think, have resulted had circumstances been more favourable. I have never seen hypnotism weaken the character where it has been properly used; but on the contrary it is interesting to note the almost invariable improvement in disposition which takes place

* The Dalrymple Home, Rickmansworth, is one of the best-known and best-managed retreats in the country. In its report for 1899 it states that, of the 518 men who had passed through it since it was opened, 169 are doing well. This proportion and mine may appear small alongside of systems which 'never' fail, or which claim to cure over 90 per cent. The explanation lies in the fact that our reports give a more accurate account of what happens. It is easy enough to coax a drunkard into sobriety for a few weeks, and then to claim him as a cure. In one well-known instance twelve drunkards were treated by a vaunted specific, and it was reported in three months, with great flourish of trumpets, that they had all been cured. Alas! I am informed that after twelve months every one of them had relapsed. Inebriates are generally emotional, and easily acted upon by their environment. Well fed, petted, flattered, the excitement of their new situation sufficed to keep them sober for a few weeks. But the object achieved by the advertisers, their attentions to the patients ceased, they were thrown on their own resources, and speedily resumed their old habits. It will be noticed in the accompanying table how many of my patients relapsed after three months, and I look on that as a somewhat critical period.

Case.	Sex.	Date.	Age.	Condition.	Nature of Surroundings.	Duration of Habit.	Degree of Hypnotism.	Result.
1	M.	Dec., 1888	43	Married, ex-captain	Favourable	3 years	3rd	Cure. No relapse
2	M.	Jan., 1889	34	Married, merchant	Favourable	3 years	2nd	Cure. One relapse in June, 1889
3	M.	Feb., 1890	30	Married, clerk in S. Africa	Unfavourable	2 years	4th	Relapse after 15 months
4	M.	Feb., 1890	35	Single, ex-officer	Unfavourable	17 years	6th	Cure. No relapse
5	M.	Feb., 1890	45	Married, artist	Unfavourable	Over 10 years	4th	Much benefited. Occasional outbreaks
6	M.	Mar., 1890	34	Married, country gentleman	Favourable (H)	7 years	3rd	Relapse after 7 months, but permanently cured now
7	F.	April, 1890	41	Wife of solicitor	Favourable	Over 5 years	4th	Relapse after temporary benefit
8	F.	May, 1890	40	Single, shop assistant	Unfavourable	Over 10 years	5th	Relapse after temporary benefit
9	M.	June, 1890	27	Single, tutor	Favourable (H)	3 years	1st	Relapse after temporary benefit
10	M.	June, 1890	60	Married, merchant	Unfavourable	Over 10 years	2nd	No effect
11	F.	Dec., 1890	40	Wife of clergyman	Favourable	7 years	1st	No effect
12	M.	Dec., 1890	42	Married, clergyman	Unfavourable	Over 10 years	2nd	Relapse after 3 months
13	M.	Feb., 1891	30	Married, merchant	Unfavourable (H)	4 years	6th	Apparently cured, but died after 6 months
14	M.	Mar., 1891	27	Single, country gentleman	Favourable (H)	5 years	3rd	Relapse after 8 months, but permanently benefited
15	F.	Sept., 1891	42	Wife of merchant	Unfavourable (H)	4 years	3rd	Cured
16	F.	Sept., 1891	28	Wife of naval officer	Favourable (H)	5 years	3rd	Much benefited
17	F.	Nov., 1891	32	Wife of clerk	Unfavourable	5 years	6th	Relapse after 3 months
18	F.	Nov., 1891	45	Wife of artisan	Unfavourable (H)	7 years	6th	Relapse after 3 months
19	M.	Nov., 1891	27	Single, surveyor	Favourable	3 years	4th	Relapse after temporary benefit
20	M.	Nov., 1891	36	Married, tradesman	Favourable (H)	7 years	2nd	Relapse after temporary benefit
21	F.	Nov., 1891	37	Married, dressmaker	Unfavourable	7 years	2nd	Relapse after temporary benefit
22	F.	Nov., 1891	24	Wife of clerk	Favourable (H)	3 years	4th	Relapse after temporary benefit
23	F.	Dec., 1891	47	Widow, housekeeper	Unfavourable (H)	7 years	5th	Relapse after 2 years
24	M.	Dec., 1891	54	Widower, gardener	Unfavourable	Over 10 years	6th	Relapse after 3 months

(H) means strongly marked heredity, and that several members of the family have suffered from chronic alcoholism.

Case.	Sex.	Date.	Age.	Condition.	Nature of Surroundings.	Duration of Habit.	Degree of Hypnotism.	Result.
25	M.	Dec., 1891	35	Married, brewer	Unfavourable (H)	7 years	4th	Has had two relapses, but is now doing well since 1 year
26	M.	Dec., 1891	40	Married, chemist	Unfavourable	3 years	5th	Cured
27	M.	Dec , 1891	40	Married, engineer	Unfavourable	4 years	1st	No effect
28	M	Dec., 1891	32	Married, tutor	Favourable (H)	10 years	3rd	Relapse after 9 months
29	F.	Jan., 1892	43	Widow, servant	Favourable	2 years	5th	Cured. No relapse
30	M.	Jan., 1892	32	Single, country gentleman	Favourable (H)	4 years	3rd	Cured
31	M.	Jan., 1892	35	Married, merchant	Favourable (H)	20 years	4th	Cured
32	M.	June, 1892	40	Lawyer's clerk, single	Favourable	Over 10 years	4th	Several relapses, but has not relapsed now for years
33	F.	July, 1892	35	Cook, single	Favourable	Over 5 years	5th	Temporary improvement, but relapsed after 4 months
34	M.	Nov., 1892	30	Gentleman, single	Favourable	Over 5 years	3rd	No effect
35	F.	Nov., 1892	22	Servant, single	Unfavourable	5 years	5th	Relapse after 2 months
36	M.	Nov., 1892	36	Lawyer, single	Favourable	4 years	3rd	Relapse after 6 months
37	F.	Nov., 1892	35	Housekeeper, single	Favourable	3 years	6th	Relapse after a year
38	M.	Dec., 1892	35	Merchant, married	Favourable	7 years	2nd	Cure. No relapse
39	F.	Dec., 1892	33	Wife of South African merchant	Unfavourable (H)	5 years	6th	Alcohol made her vomit, but she continued to drink, and the treatment had no result
40	M.	Jan., 1893	41	Captain in army, married	Favourable (H)	3 years	3rd	Temporary improvement, but relapse after 7 months
41	M.	Feb., 1893	50	Clerk, married	Favourable	15 years	4th	Relapse after 5 months
42	F.	Feb., 1893	45	Housekeeper, single	Unfavourable	10 years	4th	No effect
43	M.	Mar., 1893	40	Clerk, married	Unfavourable	15 years	4th	Several relapses, but permanently benefited
44	M.	Mar., 1893	45	Butler, married	Unfavourable	10 years	4th	Relapse after 3 months
45	M.	Mar., 1893	30	Gentleman, single	Favourable	10 years	2nd	No effect

(H) means strongly marked heredity, and that several members of the family have suffered from chronic alcoholism.

Case.	Sex.	Date.	Age.	Condition.	Nature of Surroundings.	Duration of Habit.	Degree of Hypnotism.	Result.
46	M.	April, 1893	28	Clerk, married	Favourable	5 years	5th	Cured. No relapse
47	F.	June, 1893	35	Servant, married	Favourable	5 years	5th	Relapse after 3 months
48	M.	June, 1893	39	Clerk, single	Unfavourable	10 years	5th	Relapse after 8 months
49	M.	July, 1893	40	Labourer, married	Unfavourable	7 years	4th	Relapse after 4 months
50	M.	July, 1893	45	Engineer, married	Favourable	5 years	4th	Permanently benefited
51	F.	Oct., 1893	44	Wife of chemist	Unfavourable	7 years	6th	Relapse after 2 months
52	F.	Mar., 1894	30	Lady of property, single	Favourable (H)	5 years	6th	Cured. No relapse
53	M.	Mar., 1894	52	Porter, married	Favourable	20 years	4th	Relapse after 2 months
54	F.	April, 1894	47	Wife of gentleman	Unfavourable (H)	5 years	2nd	No effect
55	F.	April, 1894	30	Nurse	Favourable (H)	4 years	6th	She took no alcohol for 2 years; then had a bad relapse. Is now again apparently cured
56	F.	May, 1894	32	Servant, married	Favourable	3 years	6th	Relapse after 3 months
57	M.	July, 1894	45	Shopkeeper, married	Favourable (H)	5 years	3rd	Relapse after 4 months
58	M.	July, 1894	34	Clerk, single	Favourable	4 years	3rd	No effect
59	F.	July, 1894	50	No employment, single	Unfavourable	Over 10 years	5th	No effect
60	M.	Oct., 1894	28	Lawyer's clerk, single	Unfavourable	5 years	3rd	No effect
61	M.	Oct., 1894	50	Gentleman, married	Favourable	15 years	3rd	Permanent improvement, but occasional relapses
62	F.	Jan., 1895	55	Wife of gentleman	Favourable (H)	12 years	1st	Permanent improvement, but occasional relapses
63	F.	Feb., 1895	50	Lady of property, single	Favourable	3 years	3rd	Cured. No relapse
64	M.	April, 1895	41	Gentleman, married	Unfavourable (H)	10 years	3rd	Occasional relapses, but general improvement
65	M.	April, 1895	42	Clerk, married	Favourable	2 years	4th	Cured. No relapse

(H) means strongly marked heredity, and that several members of the family have suffered from chronic alcoholism.

ANALYSIS: 65 cases; 39 men, 26 women. Cured, 15; relapsed after apparent cure of 2 years, 2. Died 6 months after apparent cure, 1. Much benefited permanently, 7; relapsed after 3 to 6 months, 30. No effect, 10.

under the influence of moral suggestions. It is my practice to make the suggestions in the direction of evoking the patient's own powers; and it would be manifestly wrong to introduce a personal element into the treatment, or to make the patient sober in order that he may please the hypnotist! But in many quarters that seems to be the idea of treatment, and in cases so treated I can well understand that when the personal influence of the hypnotist is removed the patient may relapse. I suggest: First, abhorrence of drink and its results; secondly, absence of craving for it; and thirdly, increased self-control, so that if temptation does arise there may be power to resist it. If the patient is only slightly influenced, or if it is only necessary to slightly supplement the power of his unaided will, these suggestions are all one need make; but if he is a person of very weak character, and is exposed to exceptional temptation, it is well to make the deterrent influence stronger by exciting a feeling of extreme physical repulsion, and this can easily be done in the case of somnambulists. One has only to tell the patient that if he takes beer or spirits they will at once cause him to vomit, and then on waking him compel him to drink a glass of beer to produce such an attack of nausea and sickness as he will remember for many a day. Even in such a case it will, no doubt, be possible for the subject to re-educate himself to like liquor, just as a schoolboy who will go on smoking, though every pipe at first makes him sick, may at last overcome the repugnance and become a confirmed smoker.

But in the combination of moral and physical influences thus produced we possess a very powerful lever. If a man has been made a drunkard through the solicitations of fast companions, his power of resistance is reduced to nil, and the offer of a drink has so often been followed by its absorption, that the sequence of events becomes automatic, an ideo-motor reflex action; but let such a man be hypnotized, and in this state be told that alcohol is poison, and that to offer him a drink is to grossly insult him—as

in a case of a confirmed drunkard reported by Surgeon-Major Neilson—and we form a new inhibitory tract, which by repeatedly being traversed becomes well worn and habitual in place of the other. But it is plain that we must not expect immediate cure. Old channels cannot be destroyed, any more than new ones can be formed, in the course of a few days.

After a period of treatment, varying in different cases, a new personality or 'conscience' is produced, and the patient can return to his former associations and friends so protected as to be safe from relapse. The time necessary for restraint or close observation is from three to six weeks, and after that he should be under observation for at least a year, and the suggestion should be repeated at lengthening intervals during that time. It is by no means necessary that the patient should spend any portion of the time in a retreat if efficient control and observation can be exercised by a trustworthy relation, friend, or attendant. We must remember that at first every public-house offers a suggestion to drink, and every boon companion calls up associations of ideas connected with former self-indulgence, and opposed to the suggestions we have endeavoured to implant.

I was recently induced to undertake the case of a medical man, whose surroundings were extremely unsatisfactory, but the patient expressed a great desire to be cured, and proved a very susceptible subject. Dipsomaniacs are notoriously untrustworthy, and in a few days I found on inquiry that his protestations were false, and that he had made no attempt to avoid temptation, but rather put himself in its way. Under such circumstances the treatment had not a chance, and as he refused to submit to restraint I at once abandoned it.

In another case, which has since turned out most successful, the gentleman had a relapse at the end of a week, in consequence of being insufficiently guarded from special temptation. He at once told me of his fault, and explained how difficult he had found it to act against

hypnotic suggestion and take the first glass of spirits. It was a real battle, so he said, with his new conscience, in which conscience nearly won the day. After a month's hypnotic treatment he seemed positively proof against temptation, and I could trust him anywhere alone. It is now some years since the treatment was commenced, and he has remained a consistent abstainer, though he has paid me four or five visits for renewal and reinforcement of the anti-alcoholic suggestions.

If the contention of many of Charcot's school and others were correct, and if hypnosis were the induction of a morbid state which takes the place of the disease, I should still consider its exhibition justified in the treatment of confirmed drunkenness; and I look forward to a time when it will be used as a matter of routine treatment in our retreats, greatly to the increased utility of those excellent institutions. Of course, many cases will resist hypnotic treatment, as they resist everything else. Such cases are, I believe, absolutely hopeless, and it will be a good thing when the law allows us to keep them under permanent restraint.

My experience is very much the same as that of other physicians who are practising hypnotism all over the world —Liébeault, Bernheim, Forel, Schrenk-Notzing, Wetterstrand, Hamilton-Osgood, Neilson, Bramwell, Kingsbury, Cruise, Woods, and others. Bérillon has contributed two papers of great interest on the subject in the *Revue de l'Hypnotisme* (August and September, 1890), which entirely corroborate the above remarks.

In the treatment of morphinomania a different course must be adopted to that pursued in managing drunkenness. In the latter the supply of alcohol had better be cut off at once, but this course would be highly dangerous in the morphia habit, even with the aid of hypnotism. The quantity may be gradually decreased, until at the end of a week the drug should be discontinued altogether. This step is followed by a gastric crisis, during which the

patient should be frequently hypnotized, and be kept up by nourishing foods and stimulants.

There are cases on record in which cures have been sudden, but I should greatly distrust their permanence except in very exceptional instances.

Many people have objected to hypnotism because they consider it as interference with freewill. Do those who talk about a drunkard's freewill understand that they are speaking of a thing which has ceased to exist? A dipsomaniac is reported to have said that if he were given a glass of whisky, and told that drinking it would immediately consign him to the pains of hell, which might be exposed to his gaze, he would be unable to resist draining the glass. An occasional success in treating such a frightful disorder would justify the trial of hypnotism in dipsomania, even if it were surrounded with ten times the dangers with which people credit it. As a matter of fact, the treatment offers considerable hope of cure even in desperate cases, and it is absolutely free from risk.

The above observations apply with increased cogency to treatment of the morphia habit by hypnotic suggestion. It is well known that this habit is more deeply impressed on the system than alcoholism, and that morphinomaniacs are even less trustworthy in their resolutions and protestations than drunkards. In treating the morphia habit, it is therefore necessary to have the patient under very efficient observation, and it is desirable to induce the most advanced degree of hypnosis possible, in order that suggestion may act with the most complete effect.

Dr. Wetterstrand records a series of thirty-eight cases, of which he treated twenty-eight successfully by suggestion (*Zeitschrift für Hypnotismus*, March, 1896).

It is very gratifying to those interested in the subject to observe how hypnotism is being taken up by practitioners all over the country, not as a speciality or panacea, but as an adjunct in the treatment of cases which have not proved very amenable to ordinary medication.

Drs. Cruise, Fitzgerald, Richard Hayes, Murphy, Redmond, and M'Cullagh, of Dublin, related cases and bore testimony to the value of hypnotism at the meeting of the Royal Academy of Medicine in Ireland, on March 6, 1891 (*Dublin Journal of Medical Science*, May, 1891). All these physicians and surgeons had made trial of the treatment, both in their private and in their hospital practice, and spoke from personal observation. Sir W. Cruise has kindly informed me that the lady dipsomaniac referred to by him and Dr. Murphy continues well, and is apparently cured. He has supplied me with information regarding other interesting cases, and among these one of diabetes mellitus. The patient is a young man whose condition was very serious. By hypnotic suggestion the urine has been reduced in quantity from 24 to 8 pints per diem, and the sugar proportionately, while the distressing thirst has been entirely relieved. Sir William says that, of course, he does not expect a cure, but it is a great thing to have been able so greatly to have mitigated the symptoms. His experience coincides with that of Van Renterghem and Van Eeden, who have been successful in their treatment of diabetes by suggestion, and who have also found it of value in Bright's disease. The treatment of diabetes by hypnotic suggestion raises an interesting question. We know that this disease is often of psychical origin, and may follow serious emotional disturbance, such as fear, anxiety, anger, and deep grief where they occur in predisposed individuals. Sometimes 'psychical shock' is combined with bodily injury, as in a case reported by Professor Senator (*vide British Medical Journal*, February 17, 1900), when diabetes came on fourteen days after lightning-stroke. Suggestion by working centrally on the nervous system may be expected in these cases to reverse the morbid process and thus effect amelioration, and perhaps ultimate cure. Dr. Draper, of Huddersfield, contributed a paper at the annual meeting of the British Gynæcological Society, held at Newcastle in June, 1891. In this he records some interesting cases

he has treated by hypnotism. One of obstinate hysterical vomiting is especially striking. Another is a case in which he found suggestion of extraordinary efficacy in relieving symptoms and promoting convalescence after he had removed the ovaries, thus corroborating my own experience in such cases. His paper is to be found in the *Provincial Medical Journal* for July, 1891. Dr. Draper tells me he has used hypnotism with gratifying results in eighteen cases of midwifery, and that he has performed a considerable number of surgical operations under hypnotic anæsthesia. Dr. Jane Walker, of the New Hospital for Women, London, records an interesting case of confinement under hypnosis in the *Revue de l'Hypnotisme*, 1896. The manner in which many English practitioners have taken up hypnotism is exactly that advocated by Professor Pitres in addressing his students at Bordeaux: 'Be physicians, gentlemen, and not hypnotizers; but learn how to apply hypnotism, and be ready to make use of it in suitable cases.'

CHAPTER VIII

Inhibition. — Definition. — Dynamogenesis. — Theories of Brown-Séquard.—Lauder Brunton.—Interference.—Experiments.

I PROPOSE in the following chapter to consider briefly the subject of inhibition, as it seems to me to be the key to the proper comprehension of hypnotic phenomena. The subject is a difficult one, and I would refer the student desirous of fully studying it to consult the works of Lauder Brunton,* Brown-Séquard,† and Heidenhain.‡

Inhibition is defined as being 'the more or less complete arrest of present functional activity of a structure or organ by a restraining influence exerted over it through a nerve centre,'§ or more fully by Dr. Lauder Brunton as 'the arrest of the functions of a structure or organ by the action upon it of another, while its power to execute those functions is still retained and can be manifested as soon as the restraining power is removed.'

It will be seen from these definitions that inhibition is quite a different thing to the loss of function which occurs in paralysis, and the cessation of function which follows exhaustion. There are two characteristics which are of great importance in the consideration of the relationship between inhibition and hypnotism: the suddenness of its induction and removal, and the want of apparent propor-

tion between the cause and effect—*i.e.*, a relatively small excitation being capable of determining most extensive results. Under ordinary circumstances stimulation of a motor nerve by an electric current produces in response the contraction of the muscles to which the nerve is distributed, and irritation of a sensory nerve produces a sensory reaction; *e.g.*, stimulation of the gustatory nerve arouses taste sensations, of the optic nerve visual sensations, etc. But stimulation of a nerve is not always followed by functional activity. On the contrary, it is sometimes followed by cessation of activity. 'Afferent impulses reaching a nervous centre may, instead of stimulating it to activity, stop or inhibit an activity previously going on. Whenever in any tissue energy is being set free, nervous energy brought to bear on the tissue may affect the rate or amount of energy set free in two different ways: on the one hand, it may increase or quicken the setting free of energy; on the other hand, it may slacken, hinder, or inhibit the setting free of energy' (Foster's 'Physiology,' p. 185).

The recognition of the part inhibition plays in vital phenomena is undoubtedly one of the most important discoveries which have been made in physiology since Harvey discovered the circulation of the blood. It throws light upon an immense number of phenomena previously inexplicable, and enables us to form theories of a satisfactory nature about many vital problems. It offers an explanation of the nature of hypnotic states, which is at least as satisfactory as that we have of the action of many drugs.

The nervous mechanism of the heart affords the best and most commonly cited example of inhibitory action, and here it was first studied by Weber and Claude Bernard in 1848. The cardiac ganglia derived from the sympathetic preside over the movements of the organ, and in response to the stimulus of the intraventricular blood-pressure cause rhythmical contraction of the cavities. Their action is, however, controlled by the pneumogastric

nerve, through which impulses of an inhibitory nature are constantly travelling and acting as a restraining force. Paralysis of the pneumogastric, of course, does away with its action, and hence we have, among other symptoms of this condition, increased rapidity of the contractions of the heart from withdrawal of the inhibitory influence. This is demonstrated by dividing the pneumogastric in animals, and it has also been seen in cases where it has been possible to exert pressure on the nerve in men. Thus, the late Professor Czermack had a small glandular tumour in close contact with the right pneumogastric nerve, and he was able by pressure on this to compress the nerve to any extent he wished, and either to completely stop the heart or simply to retard it (Lauder Brunton, 'Inhibition,' West Riding Reports, 1874).

If when the heart is beating regularly, the branches of the pneumogastric going to it are stimulated by the passage through them of an interrupted electric current, the heart will stop beating, and it will be found flaccid and in a state of muscular relaxation. This happens when the current is of sufficient intensity; but it may be insufficiently powerful to stop the action altogether, and in that case we shall see all degrees of interference from mere slight retardation to complete arrest.

But the action of the heart may be inhibited by influencing it through the pneumogastric in other ways. Golz's tapping experiment illustrates this. He exposed the heart and vessels, and also the intestines, in a frog, and he found that tapping on the intestines with the scalpel handle had the effect of stopping the heart. The practical bearing of this experiment is seen in cases where sudden death follows a blow on the stomach or abdomen. The heart is stopped by an intense stimulation of the pneumogastric through its gastric branches.

These examples show the effect of inhibition of mechanical origin, but we constantly see how the heart may be inhibited by influences of psychical origin. If the stimulation is intense, and the organ weak, absolute

stoppage of the heart may ensue; and as it is with the interrupted current, so it is with the effects of emotion and shock. The heart may either stop or its action may simply be interfered with.

As in the heart we find two nervous agencies at work, the one exerting an exciting and the other a restraining influence, so it is in respect to all our functions and organs. There is a system of action and counter-action, and in a state of health there is a proper relative balance maintained between the two. There is interaction of nervous force, and no function or organ in normal life has full and unrestricted play, for its activity is modified by the interferences of nervous impulses arriving from other parts. Some of these impulses are of an inhibitory nature, and the amount of response to stimulation depends not only on the strength of the stimulus, but also on that of the counteracting inhibitory impulse. For example, a person receives a violent blow, and a nervous impulse of great force and tension is sent from the seat of injury to the brain centres. The natural response to the stimulus will be a correspondingly strong discharge of energy from the receiving centres along the motor tracts, and vigorous muscular contraction taking the form of retaliatory violence will result; this action may be called cerebro-reflex, and the less the injured person is controlled by reason, the simpler will be the mechanism of the act. But in educated and disciplined communities, cerebro-reflex movements are not allowed their full play, for the functions of the highest controlling centres come into action; and in addition to excito-motor impulses sent from the motor centres, there are other impulses discharged from the centres of the highest level, and these will be of an inhibitory nature, and will modify those emanating from the lower levels. If the assaulted person has so developed his faculties of restraint and judgment that they have become the dominant features of his character, he will reflect that instead of returning the blow, it may be better to either take no notice of it,

or proceed by legal action. In either case a strong inhibitory impulse from the highest centres will neutralize the cerebro-reflex one. If the injury is severe, or the power of restraint not fully developed, the action of the highest level may not be sufficient to entirely neutralize the reflex response, and the fist may be clenched or a cry uttered. It is evident, then, that not only function, but conduct also, depends largely on inhibition.

The controlling action of the highest centres in inhibiting cerebro-reflex action is seen in the exaggerated start a person makes on receiving a sensory impression when his mind is not ready to receive it; for instance, the touch of a friend's hand on the shoulder will cause one to almost jump from the chair, if the faculties of attention are off guard, or if one is in a state of reverie. Similarly, in hypnosis (inhibition of the cells of the highest cortical centres) reflex actions are generally exaggerated.

Inhibition may be either very extended in its action or extremely circumscribed. An example of the former is seen in the tremendous effect which follows irritation of the small mass of gray matter (the vital knot) situated at the upper part of the medulla oblongata. An intense inhibitory impulse is discharged, and the result is instant death from fatal interference with the functions of the heart and lungs: general inhibition is produced. Its confinement to a very small area is seen when the auriculo-cervical nerve in a rabbit is irritated. Paralysis from inhibition of the vaso-motor nerves of the ear is produced with immediate flushing of the part. Brown-Séquard has obtained some typical illustrations of inhibitory action. By passing carbonic acid through the upper part of the larynx of a dog, and so irritating the peripheral endings of the laryngeal nerves, respiratory movements were at once checked, though communication between the lungs and the external air was freely maintained by means of a tube, and though the gas was prevented acting on the bronchial mucous membrane by division of the trachea. On the other hand, when he irritated the pharyngeal

mucous membrane by directing the vapour of chloroform upon it, he found that the contrary effect was produced, and respiratory movements became greatly exaggerated and accelerated, though the quantity applied was very small, and it was prevented reaching the lungs.*

In the case of general inhibition of vital functions following irritation of the vital knot, we have seen the most intense and widespread action of this force, and in the different degrees of cardiac interference produced by stimulation of the pneumogastric we have an example of a more localized but still intense form of inhibition. As Nasmyth's hammer can either weld a gigantic bar of steel or crack a walnut, so inhibition has all grades of action, and its effects may be extremely circumscribed or widespread.

For example: No function of organic life is more influenced by mental states than that of salivation. The thought of savoury food when one is hungry is sufficient to make the salivary glands secrete and the mouth water, while fear or disgust will have an exactly opposite effect, and the mouth becomes dry and parched.†

* Brown-Séquard has pointed out how in the oncoming of sleep inhibitory impulses affect different muscles in order: the eyelids become heavy from inhibitory action on the levatores palpebrarum, the head tends to fall from inhibition of the muscles which support it. At the same time an inhibitory impulse affects the heart and lungs, and the action of these become slower. Consentaneously the mental faculties become dulled and inactive from their inhibition. In using hypnotism one endeavours by word-painting to figure in the subject's mind an image of these natural processes, relying on suggestion being followed by realization of the conditions suggested.

Brown-Séquard quotes the experiments of Fleming and Augustus Waller, showing how simultaneous pressure on the cervical sympathetic, the pneumogastric, and the carotid determines sleep. He supposes that these procedures act as peripheral irritations which are carried to a certain point—situated probably at the base of the brain—and that from this point proceed inhibitory impulses which affect the functioning of the different centres (*Archives de Physiologie*, January, 1889).

† This effect is taken advantage of by some of the Indian tribes. If a man is suspected of a crime he is given rice to chew, and told to spit it out. The guilty person is so affected by terror that the rice is reduced to a fine dry powder, in consequence of the absence of saliva, whilst if innocent it is ejected as pulp. But the function of the salivary glands can be influenced mechanically, in the same way as that of the

Tarchanoff gives some interesting examples of inhibitory action, and the following are selected from his book :

If the posterior limbs of a frog be plunged into a weak acid solution, the animal will withdraw them at once ; but if at the same time the middle region of its brain be stimulated by an electric current or by a solution of salt, the movement does not take place, because the reflex movements have been inhibited by the action induced in the brain.

If a section of the upper part of the spinal cord of a frog be removed, and the remaining portion be connected with the brain by a circuit in which a galvanometer is placed, the needle will be observed to oscillate periodically from the passage through the circuit of nerve impulses proceeding from the bulbar centres, and this movement will continue for some time ; but if a nerve in connection with the cord be irritated, it will be found that the needle will become motionless as long as the irritation is kept up. We here see that nervous action can be inhibited in the brain centres by peripheral stimulation, just as in the previous example reflex action was arrested by acting on the cerebral centres.

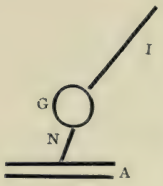
Tarchanoff argues that external sensory impressions act as inhibitory or moderating influences on the nervous centres of the brain, and that in hypnosis, as there is an absence of these impressions, the phenomena of excitation of the centres are no longer counterpoised, and are, therefore, in the ascendant. To support this view he instances an experiment he has made on a young dog. He exposed the motor area of the cerebrum, and stimulated it to action by applying an electric current. This procedure was found to excite localized movement, according to the zone experimented on ; but when he held a piece of meat to the animal's nose, he found the movements ceased ; *i.e.*, the excitation of the centres of smell and sight produced an inhibitory action on the motor centres. To enforce the same theory, he quotes an experiment performed on dogs by Heidenhain and Boubnoff. They find that when dogs are poisoned by morphia, so that ordinary external impressions cease to act upon the brain, irritation of the motor zones produces strong tonic contractions, which continue after the excitation has ceased ; but if other parts of the gray matter be gently stimulated, the contractions at once cease ; and the same effect is observed if the senses of sight, hearing, smell, or touch be peripherally excited. He draws an analogy between the morphinized dog and the hypnotized subject, and seeks to show how in the latter case hyperexcitability of the muscular system and senses exists, in consequence of the absence of many-sided impressions from the closure of all the avenues of sense, except those specially excited.

The accompanying diagram shows how inhibitory action affects the calibre of an artery, and consequently the blood-supply of a part. G is a nerve ganglion connected

---

heart. Take the submaxillary gland. It is supplied with vaso-motor nerves, which keep its vessels moderately contracted when food is not being taken. A branch of the chorda tympani nerve seems to act as inhibitory nerve of the vaso-constrictor fibres of the vessels supplying the gland, and irritation of it has the effect of causing dilatation of the vessels, with consequent increased afflux of blood and increased functional activity—*i.e.*, increased flow of saliva.

with the artery A, through a nerve N, and I is a centrifugal nerve derived from an inhibitory centre. Under ordinary circumstances G is constantly acting on A as a vaso-constrictor, and keeps its walls moderately contracted. When, however, an inhibitory impulse arrives at G through I, the action of G is arrested and restrained, and the vessel A is free to dilate.



Lauder Brunton thinks inhibition of secretion may result either from interference with the supply of blood to an organ, with consequent cramp of the arterioles and local anæmia, or from direct action of inhibitory nerves on motor cells without any changes occurring in the vessels.

Brown-Séquard supposes that where on the one hand there is an inhibitory influence at work, there is also present on the other hand its antithesis—dynamogenesis. Nervous force cannot, any more than other forms of energy, be created ; it can only be transformed and made to act in altered combinations and different directions.

Thus Beaunis says that every nervous excitation determines in the excited nervous substance two contrary modifications, an impulsion towards activity and a tendency to inhibition. Similarly Lauder Brunton considers that inhibition is the opposite phase to stimulation, that both depend on excitation, and that the resulting condition depends upon the force with which and the direction from which their mutual interference acts.

It has been generally held that inhibition is the property of special nerve centres situated in the brain and spinal cord, and that from these proceed nervous discharges of an inhibitory nature, in the same way as from motor centres proceed motor impulses. It is proved that the higher centres of the brain exercise an inhibitory action on those below them, and that these again control the next below them, and so on. Reflex action increases in proportion to the removal of the control of the higher

centres, not only in the brain but also in the cord, for when the cord is removed in segments we find the excitability of the segment below increases with the removal of the one above. So the activity of the lower cerebral centres will become more apparent in proportion to the removal of the control of the higher.

The heart, again, affords one of the best examples of the close association of neuro-regulatory arrangements and their action upon each other. If the heart is removed from a cold-blooded animal, it will continue to contract rhythmically owing to its containing within itself ganglia derived from the sympathetic system. But these ganglia have not all the same functions. The principal ones, three in number, are those of Bidder, Remak, and Ludwig. The two former appear to be excitor centres, while the latter is a moderating or inhibitory centre. This is well shown by experiment. Let the heart be cut into two unequal portions, one consisting of the right ventricle (with the ganglion of Remak), and the other of the two auricles and the left ventricle (containing Ludwig's and Bidder's ganglia), the first portion will continue to beat, but the second will remain quiet. Let this second portion be again divided, and the auricles (containing in their septum Ludwig's ganglion) will be found to remain quiet, while the ventricle will recommence beating. Ludwig's ganglion has thus proved strong enough to counteract one excitor ganglionic centre, but not sufficiently strong to control two (Küss's 'Lectures on Physiology,' edited by Amory, p. 169).

It is probable, as Brown-Séquard says, that all sensory and sensorial nerves are capable of determining inhibition, and the study of hypnotism affords a valuable confirmation of this theory. The highest centres may be inhibited by acting on several sensory areas and tracts, and the position of these seems to vary in different individuals. Gentle friction, for instance, of the forehead will in many persons speedily determine cortical inhibition and hypnosis, and some writers have even described inhibitory or hypnogenic

zones.* The phenomena of zonar epilepsy afford a useful analogy here. Slight pressure on the ovaries will in many of these cases start an epileptiform fit—*i.e.*, will convey a strong inhibitory impulse to the cortex—and the highest layer will be inhibited with corresponding overaction from dynamogenesis of the lower. Conversely, we find that strong pressure over the ovaries will cut short an attack which has begun, thus showing the close relationship between the neuro-regulatory forces. But though it is

* Professor Pitres gives an exhaustive account of these zones in his latest work. His position and experience demand our acceptance of the facts he records, but some of them, *e.g.*, the occurrence of ideogenic zones in hysterical subjects, pressure upon which give rise to various emotions and sensations according to the area stimulated, make considerable demands on our imagination. It is a matter for regret that, like Charcot, he seems to have confined his researches in hypnotism almost entirely to hysterical subjects, as experiments on healthy persons give much more satisfactory and trustworthy results. Bernheim denies the occurrence of hypnogenic zones, except as a result of conscious or unconscious suggestion on the part of the operator ; but Pitres gives evidence that it is impossible to ignore, and it is, I think, best to admit that these zones are of spontaneous origin in a few exceptional cases, just as Charcot's three stages may sometimes occur without suggestion. According to Pitres, the zones must be carefully looked for, as they are usually confined to a small area. There may be only one discoverable, or the number may mount up to fifteen or more. He describes (with diagrams) the case of one hysterical young woman having ten hypnogenic zones ; two of these were situated in the middle line, one at the root of the nose, and the other on the vertex, and eight on the left side, viz., on the malar process. the superior body of the clavicle, mammary region, bend of the elbow, upper and external part of the thigh, knee, external malleolus, and internal malleolus.

The result of touching any of these zones was that the girl fell at once into the lethargic stage of hypnosis (Charcot), and remained in it until she awoke spontaneously, or was awakened by touching other areas which acted as waking (hypno-phrenetic) zones. The danger and inconvenience arising from the existence of these zones, whether natural or acquired, is demonstrated by many cases referred to by Dr. Pitres, and if they are found to exist, hypnotic suggestion should be employed to remove them. A physician has told me that he accidentally touched one of Charcot's patients on the elbow, and that she at once passed into a state of catalepsy ; and in Luys's clinique I have seen patients who are equally subject to being in a moment reduced to a state of helplessness, and perhaps unconsciousness. Such development of hysterical phenomena, whether practised in the wards of a hospital or on a public platform, constitutes in my mind a grave abuse of hypnotism. Instead of developing the morbid hypersusceptibility of hysterical subjects by hypnotic education, it appears to me much more commendable to correct and cure it.—'Hystérie et Hypnotisme,' vol. ii., chap. 44.

certain that hypnogenic zones may sometimes exist spontaneously, we must be careful to avoid confusing them with what we may call habit zones. Nerve habits are readily set up, especially in hysterical subjects, and an artificial hypnogenic zone is easily called into being by suggestion. One would only have to tell a sensitive person that pressure on his right temple would determine the hypnotic state, and we should either at once, or in a short time, find that this action would become a hypnogenic agent.

At Amsterdam, Drs. Van Renterghem and Van Eeden sometimes awaken their patients by touching the tips of their noses, and this contact is at once sufficient to end the sleep, no matter how deep it may be. An artificial dynamogenic zone has been created. The effects of nerve habit are, of course, visible all around us. The paterfamilias who has only to take up the paper after dinner and sit in his accustomed chair by the fire, in order to almost immediately fall into a doze, is a familiar example of this condition, only a little less marked than that which we sometimes set up by hypnotism, when we give the patient a piece of paper and tell him that on looking at it he will at once feel sleepy and fall into a sound sleep. The sleep of the business man over his accustomed paper is, I believe, frequently of the hypnotic type. Though it commonly lasts only a few minutes, such sleepers have frequently told me that it refreshes them more than their night's rest; it is the rest of simple inhibition. Brown-Séquard points out that anæmia is a predisposing cause of inhibition, and it has been the experience of all observers in regard to hypnotism, that anæmic persons are often the best subjects.

The tendency of nerve habits to be formed more readily in the hypnotic than in the waking condition is shown by the fact that the subject is extremely apt to assume spontaneously, on subsequent occasions, the attitude he was made to adopt when first hypnotized. Thus, if the arm was raised at right angles to the body at the moment

hypnosis was complete, it is very probable that this action becomes in the mind an essential part of the procedure, and will be repeated on every subsequent occasion unless checked by suggestion.

The subject of inhibition has been closely studied by Sir T. Lauder Brunton, and his researches enable us to get a little nearer the comprehension of some hypnotic phenomena. He founds his theory on the analogy afforded in physics by the interference of rays of light and sound with one another when they meet in certain relationship.* When two rays of light are combined so that the crests of the waves of which they consist coincide, the light becomes brighter; but if they are thrown together so that the crests of the waves in the first ray correspond with the hollows of those in the second, mutual interference is the result, and they so neutralize one another that darkness is then produced. Applied to the nervous system, the hypothesis implies that nervous impulses travel like waves along the nerve tracts, and as long as they coincide—apex to apex, and hollow to hollow—sensation or movement is the result of the impulse; but if the coincidence be interfered with, we get more or less complete neutralization of the impulse and inhibition. The way in which waves of light may be made to mutually interfere is by causing them to pass through channels of different lengths, so that when they meet, one may be half a length behind the other, the crest of the first corresponding with the fundus of the second. In the nervous system it is a matter of constant occurrence that the impulse waves of nerve energy are travelling towards the centres through channels of different lengths, and it follows, *ex hypothesi*, that they are interfering with each other in different degrees. The whole nervous mechanism is subjected in its normal state to a mutual check system, so that a balance is automatically maintained between sensory and motor nerves, and they are influenced to a greater or less degree by impulses

* *Loc. cit.*

arriving from the higher centres—*i.e.*, those concerned in volition, etc.

Lauder Brunton illustrates this point by taking the case of tickling. Here convulsive muscular movements are set up by gentle continuous irritation over a sensory surface. An impulse made up of waves is promulgated to the sensory centres, and reflected from them down the motor tracts. The stimulation being monotonous, continuous, and consisting of currents of the same intensity, there is no wave interference, and the motor movements resultant are reflex. But let the pressure be increased so that instead of tickling pain is produced: then, in place of a weak current travelling up one nervous channel, we have a strong irregular impulse disseminated into channels of different lengths; when it arrives at the centres which have been subjected to interference, a different condition will result, and the reaction will cease to be merely reflex.

Up to a certain point the action of the will may be called forth to check the convulsive movements, and this will operate by interference; the waves constituting the impulse from the highest centres so impinging upon the excito-motor waves as to cause interference and inhibition.

Inhibition, therefore, according to Lauder Brunton, is not a special function of certain cells and nerve fibres, but may be produced through any sensory or motor cell, and depends not on the properties of the cell, but on its relationship to other cells or fibres. 'Motion, sensation, inhibition, or stimulation, are not positive, but simply relative terms, and stimulating or inhibitory functions may be exercised by the same cell, according to the relation which subsists between the wave-lengths of the impulses travelling to or from it, the distance over which they travel, and the rapidity with which they are propagated.'*

* Lauder Brunton, discussing the action of atropia on frogs, shows how the animal gradually loses, first, the power of voluntary motion,

Applying the theory of interference to the induction of hypnosis, we find that it serves to explain several points. Take hypnotization by the method of fixation, for example. An intense and unusual stimulus is applied to the optic nerve, and by it carried to the optic centres, in the form of an afferent current of abnormal form and intensity. The effect of such strong stimulation is not confined to the receiving centre, but overflows it and acts upon neighbouring and associated ones. The nerve impulse thus sent through the communicating nerve fibres is composed of waves which meet the normal currents traversing these channels in such a way as to interfere with and neutralize them, and hence we arrive at inhibition, either complete or in part, of the functions of many or a few of the cortical centres. The condition once induced, its reproduction is rendered easy by the setting up of a nerve habit. Psychical processes, such as auto or verbal suggestion, may be supposed to cause hypnosis by originating a nerve impulse, starting from the ideational centres; but as to the nature of that nerve impulse it is impossible to dogmatize. Myers says that psychical processes can never be explained by physiological theories, but the physiologist will not readily admit that proposition. Inhibition, therefore, is interference, not abolition of function, and its distinguishing characteristic is its imme-

---

next the power of directing its movements, then the power of springing at all, and finally reflex action, and argues that the drug lessens the functional activity of nerve cells and fibres. The impulses are retarded, and thus the length of nervous connection between the cells of the spinal cord which is calculated to keep them in proper relation in the normal animal, just suffices at a certain stage to throw the impulses half a wave's length behind the other, and thus to cause complete inhibition and apparent paralysis. The paralysis is only apparent, for after a time the animal will be found to respond to slight stimulation in the same manner as if it had been poisoned with strychnia, *i.e.*, in an exaggerated degree. He explains this by assuming that the retardation of the impulses proceeds as the poison continues to act, so that the waves after a time interfere less and less with one another, and finally again coincide. The effect of the coincidence is increased excitability on stimulation. This is on the theory that impulses reach the centres by different routes of varying length, so contrived that in normal life a constant relationship is maintained between the position of waves, and a healthy balance is maintained.

diate production and removability. By suggestion we may be supposed to start an impulse from the higher centres, the waves of which are propagated to the centres it is sought to influence, and which either coincide with and strengthen the efferent waves proceeding from these (dynamogenesis), or by interfering with them cause inhibition.

CHAPTER IX

Natural Analogies of Hypnosis. — Relation of Hypnosis to Sleep and other Conditions.—Theory of Hypnosis.—Leucomaines and Animal Alkaloids.

In the foregoing pages I have endeavoured to show that the hypnotic state has many analogies in ordinary life, and that it is not so much the creation of a new condition as the exaggeration of normal or partially normal ones. It is the intentional production of a psychical state, similar to many which occur spontaneously in all persons under certain circumstances.

The phenomena of hypnotism have points in common with those of natural sleep, reverie, mental concentration, intense nervous excitement, religious ecstasy, post-epileptic states, as well as with the effects produced by alcohol and various drugs. There is also a close resemblance between some forms of hypnosis and hysteria, and the affinity between spontaneous and induced catalepsy and somnambulism is obvious. The distinguishing and characteristic feature of the hypnotic state is increase in the ideo-motor, ideo-sensory and reflex excitability of the brain, shown by increased readiness to receive, and increased ability to act upon suggestion.

To elucidate more clearly the rationale of hypnotism, I propose in the following pages to consider briefly the physiology of conditions resembling it, and the main points of difference between them.

I cannot but think that Bernheim has somewhat exaggerated the closeness of the analogy between hypnotic and natural sleep. To outward appearances the resem-

blance is certainly complete: hypnosis may pass into natural sleep; and sleep may partake of the characteristics of hypnosis in the same way that sleep may merge into coma, or may pass into an epileptic condition; but there are clear lines of demarcation between all these states, and the sleep of everyday life is distinct from its hypnotic counterfeit.

A short review of the etiology of natural sleep will render it more easy to understand the physiology of hypnotism. Sleep seems to depend upon several causes, and to be the resultant of their joint action. Some of these are of external and others of internal origin. First, there is exhaustion of potential energy in the brain cells, resulting from their functional activity; secondly, there is a condition of cerebral anæmia; and, thirdly, there is an accumulation in the tissues, and especially in the brain centres, of waste products. To these we must add the factor of periodicity—that ebb and flow of organic life which has so potent an influence in all vital phenomena. To insure sleep it is necessary that these agencies should be assisted by other conditions, and the most important of these are, the absence of exciting sensory stimuli, a comfortable posture, and a state of mental tranquillity and repose. Sleep is banished if there is cerebral congestion, if the mind is in a state of turmoil or excitement, or if stimulating and vivid sensory impressions are constantly arriving at the highest centres. Muscular repose is also, as a rule, a necessary preliminary to sleep, though there are many instances in which soldiers and others under circumstances of exceptional fatigue have not been prevented from sleeping in the most strained and uncomfortable positions, any more than they have been kept awake by the continuous roar of battle or the blustering of the gale.

The chemical theory that sleep results from the accumulation of waste products (leucomaines) in the organs is now very generally held. Preyer supposes that kreatine and lactic acid are formed during the periods of mental

activity, that they accumulate in the brain centres, and from their affinity for oxygen rob the cells of this element, upon an abundant supply of which their molecular activity depends. A sleeper from this point of view may therefore be considered as narcotized by the waste products of his own tissues. This theory also explains the periodicity of sleep, for these products are being constantly formed from tissue change during wakefulness, and as their quantity increases, they cause proportionate and progressive drowsiness, and finally sleep. During sleep or inactivity of the cerebral centres no formation of these products takes place, and the accumulation is gradually worked off and eliminated; a supply of oxygen again becomes available, and molecular energy is restored. When recuperation is complete waking ensues, and the same process is again repeated. It has, moreover, been found that the vital alkaloids formed during sleep have a convulsive and stimulating action on the nerve-centres, whereas those which are formed during the day have a sedative and narcotic effect. The oxygen, which is so essential to the functioning of the highest centres, is partly derived from the blood, so that the cerebral respiration is a term in use, and is partly contained in a loosely-combined state in the nervous tissue, in the same way as the oxygen required for the explosion of gunpowder is contained in the nitre of its composition (Lauder Brunton). The amount of oxygen, therefore, contained in the nerve tissue regulates the activity of the nerve cells, and when the German physiologist said that there was no thought without phosphorus, he might have added, nor without oxygen. Nerve energy is liberated by the explosive combination of the carbonaceous elements in the nerve tissue with oxygen, and if the supply of oxygen is adequate the explosive movements which initiate nervous impulses are vigorous and their psychical concomitants are correspondingly vivid. The necessity there is for oxygen for brain processes is shown by the benumbing and soporific effect of working in a crowded, ill-ventilated room. The

cerebral respiration is affected long before that through the lungs.

Brown-Séquard* thinks that sleep results from inhibition, pure and simple, and supposes that the inhibitory impulses proceed from the neighbourhood of the medulla. He contends that the drowsiness of indigestion is not produced by the formation and accumulation of leucomaines of abnormal quality, but arises from impulses of gastric origin, affecting the inhibitory centres through the pneumogastric.

There is almost as great a difference between the profound, dreamless, and physiologically perfect sleep of the healthy labouring man who earns his bread by the sweat of his brow and is untroubled by nerves, and the stuperose condition of the overfed and under-exercised dyspeptic, as there is between natural sleep and hypnosis. The reason of this appears to be that healthy physiological sleep is the outcome of all the causes I have enumerated, acting in their proper and just relationship and proportion, whereas in the sleep of indigestion we have one cause acting in excess — the accumulation of waste products and alkaloids in the tissues, as a result of imperfect assimilation and metabolism. The sleep is incomplete and one-sided here just as it is in hypnotism, and in both cases some of the elements of natural sleep are wanting. As in cases of indigestion, with somnolence and disturbed sleep, there are degrees of disturbance, varying from slight abnormality to complete change of type, so in hypnotism we see all degrees of hypnosis, from the condition, such as

* 'Archives de Physiologie Normale et Pathologique,' January, 1889. He has demonstrated the fact that pigeons continue to sleep at regular intervals after the sympathetic nerves in the neck have been divided, and that dogs and cats sleep after removal of the superior cervical ganglion of one side, and division of the vago-sympathetic in the other—procedures leading to continued dilatation of the cerebral vessels, and thus proving that sleep does not depend so much on contraction of the vessels with consequent cerebral anæmia as has been supposed. Moreover, he finds that pigeons continue to sleep after the removal of the lobes of the brain, from which he concludes that sleep does not result from influences of medullar origin, and is not dependent on the state of the cerebral lobes.

is seen in Charcot's cases, which has only a distant resemblance to normal sleep, to a state indistinguishable from and passing into it. The difference in type appears to depend upon the extent to which one factor is producing the condition to the exclusion of the others—whether the state is an auto-narcosis from the accumulation of alkaloids, is the result of inhibition alone, or is a combination of all the causes which go to make up normal sleep.

There is ground for believing that natural sleep assumes the hypnotic type much more frequently than is commonly supposed; *i.e.*, the sleeper is susceptible to suggestion from without. It is certain that many persons who are hypnotized for the first time, and the majority of those who by frequent repetition of the process have become good subjects, do not require any special stimulation of one sense for the production of hypnosis; expectant attention and verbal suggestion being sufficient to determine the condition. Those facts are calculated to upset many of the theories of the causation of hypnosis, and to confirm the dictum of Brown-Séquard that hypnosis does not depend upon exhaustion, but is a result of dynamic inhibition of the highest centres.

When Braid's method is employed, an intense strain is put upon the visual apparatus, and an excessive discharge from the cells of the visual centre is followed by its exhaustion and subsequent cessation of its functional activity. But in Bernheim's method there is no such localized stimulation and nervous exhaustion, and the condition induced would be indistinguishable from ordinary drowsiness or sleep, were it not that the subject is receptive of suggestion. The chemical theory would also be explanatory of the phenomena of Braidism, but it quite breaks down when the suggestive method of inducing hypnosis is in question. The increased functional activity of a centre must lead to the increased oxidation of its elements, with increased formation of the products of molecular disintegration (vital alkaloids); and we know that the accumulation of these in the system is a cause of

drowsiness and sleep. It is possible that their accumulation in one part of the brain may induce partial or complete inhibition of certain centres, with consequent interference with or abolition of their functions (*Tarchanoff*).

Healthy, dreamless sleep depends upon temporary abolition of the functions of the highest centres, together with a partial inhibition of those below—the middle and lower levels. In dreamful and disturbed sleep inhibition is less complete, and certain areas continue to discharge nervous energy and so produce dreams. The more intense the discharge, the more vivid the dream; and if the discharge be very intense, the attending process may overstep the limit of mere ideation and take the form of action: there will be movement or sleep-walking from stimulation and discharge of the motor areas. The actions will be unaccompanied by consciousness: for consciousness depends upon the functioning of all the higher centres in orderly relation, and in somnambulism this order is disarranged or destroyed. The actions, being unconscious, are automatic, and tend to partake of the nature of those usually or habitually performed: will be in keeping with the character and temperament of the sleeper; for the nervous discharges will travel through well-worn and accustomed channels, and will hardly effect new combinations or movements.

The post-epileptic state shows some very important resemblances to hypnotic somnambulism; the researches of Dr. Hughlings Jackson and other observers enable us to understand its phenomena.

The central nervous system may be considered as composed of three divisions or layers: first, the medulla, pons, and basal ganglia, which function the most organized processes of the animal economy, *i.e.*, nutrition, secretion, respiration, circulation; secondly, the motor areas of the cortex, which function muscular movements; and thirdly, the highest and last evolved cortical centres, which control and regulate the actions of those below them, and which produce new associated movements. Further-

more, we must suppose that these highest centres are assigned different grades in the hierarchy of the nervous system: it is the function of the highest of all, which are those last evolved, to control those immediately below them, and through them to exercise a governing influence over the entire nervous mechanism. It is only the functioning of these highest of all centres which is accompanied by psychical processes and is attended with full consciousness.

If the functioning of all three divisions is suspended, death ensues, and if the two higher divisions are entirely placed out of action, and the lowest only functions, with enfeebled force we get a state of coma, in which the patient lies absolutely motionless and unconscious, and out of which he cannot be roused. In this state, the functions of organic life alone continue, and they only with greatly diminished activity. Such are the coma of apoplectic states, alcoholic poisoning, etc. In these cases the condition depends upon destruction of the properties of the highest nervous arrangements, either from gross lesion or from chemical changes. One sees a somewhat similar condition produced by exhaustion of nervous elements in post-epileptic coma.

In natural, sound, dreamless sleep, we also get the action of the two highest divisions of the nervous system completely suspended, but the sleeper can be easily aroused, because the suspension depends to a great extent on cortical inhibition. In sleep accompanied by dreams there is incomplete suspension, and certain areas of the highest division continue to function apart from their usual combinations, and therefore more or less unintelligently.* If the action of the discharging

* An experiment referred to by Heidenhain and also by Gerald Yeo serves to show how completely the higher cerebral faculties are in abeyance in the profounder states of hypnotism. Both these authors refer to the production of the 'echo voice.' This is produced by stroking the back of the subject's neck with the hand, when he will at once repeat any words said to him. The effect produced is curiously like that experienced in listening to a phonograph. The subject may be perfectly uneducated, and yet he will repeat accurately after the

centres is energetic, it will, as we have seen, be accompanied by movements, and somnambulism may result. In hypnosis brought about by suggestion, cessation of function does not depend upon exhaustion, but is the result of inhibition, and is not therefore followed by exhaustion; on the contrary, it refreshes the system in the same way as, and in a marked degree more than, natural sleep. The awakening is immediate, and depends upon the removal of the inhibitory influence. If the phenomenon depended upon exhaustion of the nervous elements, time and rest would be required for recuperation, and this we know is not the case.

Hypnotism cannot, I believe, produce epilepsy *de novo*, even though it be employed ignorantly and recklessly; but under such circumstances it may determine a latent tendency. In hypnotizing epileptics, it is by no means uncommon to see a slight fit produced by the process. The same applies to the administration of chloroform and the ingestion of an excessive quantity of alcohol, and tends to show that in each case the agent acts on the cells of the same cortical area. The view put forth by Dr. Hughlings Jackson, in discussing epileptic convulsions, that the

---

reciter an ode of Horace or the chorus from a Greek play (compare case on p. 75). An analogous experiment on a frog, deprived of its brain, illustrates how completely the profoundly hypnotized subject may be said to be 'robbed of his cerebral hemispheres.' If the frog's flanks be gently stroked, it will croak, not continuously, but each stroke will be followed by a croak, so that Yeo supposes there is an unknown relation between certain sensory surfaces and the speech centres (*op. cit.*, p. 13).

Another experiment is that of making a person speak by placing the hand over the left temple, the idea being, of course, to stimulate Broca's speech centre underneath. The subject will at once answer if spoken to; but if the same place be again touched he will as suddenly become silent, though he may be in the middle of a word or sentence. I have seen several such experiments, but have hitherto been unable to repeat them on unprepared subjects. Heidenhain and the other writers of more than a few years ago were not so fully alive to the extraordinary readiness of the subject to act upon suggestion, and to take advantage of the smallest hint as we are now. The subject's mind is like an extra sensitive plate. As the faintest light will affect the one, so will the slightest hint influence the other. Without denying that somatic reactions may occur in the hypnotic state, I think we should be very cautious in accepting them.

highest level of the cortex not only subserves the psychical processes which constitute the physical substrata of consciousness—volition, thought, emotion, judgment, etc.—but also represents, though very indirectly, muscular movements and organic functions, throws an important light on the action of hypnotic suggestion on vital processes.

The action of hypnotism is probably exerted entirely on the highest centres, and if these represented only mental processes, it would be difficult to understand how by affecting them we could produce the changes in nutrition and function which undoubtedly result from hypnotic suggestion. But if it be correct to suppose that we can influence the functions of the lower centres by acting directly on the highest, that by influencing the hierarchy we can modify the behaviour of the subordinate functionaries of the body, we hold a key to the solution of the problem. According to Liébeault, we attack disease and affect function in gross by acting upon the starting-point and centre of vital processes (the cerebrum) instead of addressing ourselves to the treatment of their peripheral manifestations, and attacking these in detail by drugs.

I believe all physiologists are now agreed as to the effect the higher centres of the cerebral cortex are able to exert over the lower nervous arrangements. Professor Morselli of Genoa writes: 'Every mental state and every act of the intelligence has its centrifugal equivalent.'* 'The mental functions act as supreme and constant regulators of all the nervous processes, even of those which are purely automatic and are not attended with consciousness. Though they are withdrawn from the direct influence of the psychic activity, they are nevertheless dependent on it.'†

Bernheim contends that 'the brain controls all the organs and every function, and that each part of the organism has its ultimate representation in a brain cell,

* 'Fisiopsicologia dell' ipnotismo,' p. 14.
† *Ibid.*, p. 24.

which is its *primum movens*.* Each movement is realized by a cortical motor centre, and each tactile, visceral, and muscular sensation by a cortical sensory cell.'

He considers that all the organs and functions are subordinate to psychic states, and that by determining these states we can influence function.† In the earlier part of this work I have quoted numerous instances showing the connection between psychical states and organic functions, but in these the psychic influence has for the most part been accidental and undirected, and the resulting reaction has not infrequently been more harmful than beneficial. Hypnotism enables us in many cases to control this influence and direct it into proper channels. I would compare the effect of emotional states to the conduct of the master of a large establishment. As long as everything goes on well his interference with minutiæ is not required, and would probably be harmful. Every foreman and servant knows his place, and the work is regulated as it were by clockwork. But let some grave source of danger or difficulty arise, and we shall find that the master's hand is needed to control his subordinates and to prevent confusion and damage arising. Suppose that, instead of orderly and necessary interference, his conduct is guided by passion or dictated by panic, and what do we find? Instead of his action being beneficial, it is injurious, and even disastrous. Action of the incompetent or panic-stricken master is comparable to the misdirected and haphazard influence of the higher centres on the general health and functions in emotional states: while the beneficial influence exerted by a cool-headed and capable one is paralleled by the influence the higher centres can be made to exercise over the lower by means of hypnotism.

Sir T. Lauder Brunton quotes a case which he considers strongly corroborative of his view that the highest layer of the cortical cells controls the functioning of the lower

* 'Hypnotisme, Suggestion, Psycho-Therapie,' p. 449.
† *Ibid.*, p 46.

centres, and that it has an influence even over reflex actions. A patient under the care of Sir J. (then Mr.) Crichton Brown was attacked with facial erysipelas, which spread by metastasis to the brain. The man showed symptoms of cortical irritation, and examination showed that the reflexes were abolished. The disease progressed, and he became unconscious, and it was then found that the reflexes had returned. The patient died, and the autopsy revealed degenerative changes in the cortex.

Dr. Lauder Brunton, therefore, supposes that nerve currents set in motion by irritation of the brain, or some of its convolutions transmitted down the cord, may inhibit reflex action.* Dr. Mercier† and other writers on insanity point out how disease of the highest centres is nearly always accompanied by disorder of nutrition. This is especially seen in the alteration which takes place in the nails and hair, the former becoming brittle and ill-shapen, and the latter coarse and refractory. Dr. Van Eeden once showed me a little girl under treatment by suggestion for infantile paralysis. The little patient was gradually regaining the use of her legs, and a great improvement in general nutrition was apparent. In no direction was this more marked than in the toenails. For three years there had been no growth in these, and they had never required cutting; but a month after the treatment was commenced they had grown so long as to necessitate the use of the scissors, and from that time they required trimming every four or five weeks.

A few words on the foundations of consciousness will enable us to comprehend better its impairment or abrogation in the advanced stages of hypnosis. Its physical basis depends, first, on the connection of the highest layers of the cortex with the other parts of the nervous system; and, secondly, on the connection of the highest centres with each other. So that, as Professor Sir Michael

* 'On Inhibition,' West Riding Reports, 1874.
† 'Sanity and Insanity,' p. 135.

Foster says,* consciousness, volition, and other psychical processes are not the functions of the cortex, but functions of its connection with other parts of the nervous system. He asks what would happen if, while the cortex remained healthy, afferent impulses were no longer conveyed to it, and he answers that lethargy with suspension of all psychical processes would be the result. He supports this theory by citing a remarkable case, that of a man who, being deaf, and blind of one eye, became in addition affected with complete tactile and general anæsthesia, and anosmia. His only connection with 'the life of relation' was through the one sense which remained in functional activity, and when the eye was kept closed he soon passed into a condition of lethargy. Dr. Macfarlane in his recent work, 'Insomnia and its Therapeutics,' quotes a somewhat similar case: that of a girl, aged sixteen, whose skin and mucous membrane became completely anæsthetic, so that she failed to perceive the application of violent stimuli to them. At the same time she lost the muscular sense and became entirely dependent on her sight and hearing for her relationship with the outer world. Here again it happened that closing these two avenues of sense resulted in the rapid production of sleep. She could be aroused from this by stimuli acting on these senses, and she also used to awake spontaneously after a time if left to herself. These cases form an interesting antithesis to that of Laura Bridgman, who not only possessed one sense (that of touch) very abnormally developed, but also enjoyed an unimpaired coenthesis, so that the cortex of her brain was being constantly acted upon by healthy impulses. She did not therefore fall into lethargy when the tactile sense was not in use, but slept in the same way as ordinary persons.

The condition of lethargy into which Sir M. Foster's patient fell is closely imitated by the completely inert state assumed by certain hypnotized persons, especially chronic epileptics. They become perfectly lethargic,

* 'Physiology,' vol. iii., p. 117.

insensible to pain, and deaf to the loudest noises. They are not susceptible to suggestion, and can be aroused from a state resembling coma only with considerable difficulty. Dr. Habgood showed me several such cases at Banstead Asylum, and I have seen the condition induced in one of my private patients, a confirmed epileptic. In consequence of the impossibility of establishing rapport with these patients, I imagine that hypnotism would fail to benefit them.

Consciousness depends, then, on the activity of the senses, the conveyance of their impressions to the highest centres, and the association of these highest centres with each other. Anything which interferes with one or other of these conditions will weaken or destroy it in proportion to the amount of interference. In ordinary hypnosis we find the facts exactly bear out this theory for sensory anæsthesia; deadening of the senses, benumbing of the faculties, and impairment of consciousness proceed *pari passu*, and maintain a relative connection. But the coenthesis or subjective consciousness, on which to a large extent depends the *ego* or personality, is the last part of the organization to be affected.*

There is another factor in vivid consciousness. Not only must the afferent impulses from the senses and the internal organs be received by the highest centres, but the efferent impulses in response to them must be vigorous and of high tension. Vivid consciousness only exists when nervous impulses are sent through new or little-used channels, and automatism prevails when the passage of nerve energy is only through thoroughly organized tracts.

* Individuality depends upon continuous memory. Several cases have been reported in the newspapers lately of men and women who have been found by the police wandering about aimlessly and unable to give an account of themselves. There has been a complete lapse of memory, and consequent loss of individuality. In some cases the 'stream of consciousness' has resumed its equable flow, and the patient has recovered his identity. In other cases there is a complete hiatus, the past continues blotted out, and he has to literally begin life again. Most of these cases are allied to epilepsy. Hypnotism would probably restore the memory of the past, as it did in the cases of double personality referred to on p. 96 *et seq.*

In ordinary hypnosis it is the well-worn channels which are traversed, and therefore the actions performed during this state will tend to be those habitual with the subject, or at least in keeping with his character and temperament.

This point has an important bearing on the question of the employment of hypnotic suggestion for criminal purposes, and also on the possibility of using it in the reformation of bad characters. I think we may infer that hypnotism will rarely enable us to convert the hopelessly bad, but that it may be used to influence character by developing latent good and suppressing evil tendencies. It is possible, however, that by continued suggestion new channels may be formed, new tastes established, and old tracts inhibited, and eventually closed and abolished.

It is a natural corollary that when consciousness is weakened or abolished memory will be correspondingly vague and uncertain, or altogether wanting, for memory depends upon the vividness of impressions, and their arrangement and association.

Some opponents of hypnotism have nicknamed it 'tee-total intoxication'; but the analogy between it and the effects of alcohol is not very apparent. The drunken man is to a certain extent receptive of suggestion, and it is easy to foist delusions upon him, which would be rejected were he sober. The effects of alcohol show themselves in a somewhat different order to those of hypnotism. In the former we have the nervous system involved in the inverse order of its evolution, and the first part to suffer is that concerned in the highest psychical processes—memory, will, judgment, etc. In the lighter grades of hypnotism we do not find the psychical functions so much affected as those of motion and sensation, and it is common to meet with a patient who is quite unable to open his eyes, or put down his arm, if told he cannot, in perfect enjoyment of all the highest mental faculties. I have frequently tried to hypnotize intoxicated persons, but have never succeeded unless the patient has been previously hypnotized. On the other hand, chronic

indulgence in alcohol seems to somewhat favour the hypnotic process.

Sir W. Gowers* has examined the subject of hypnotic catalepsy, and has published his views concerning it. He supposes that hypnotism induces such a change in the functional state of the brain that the lower cortical mechanism is cut off from the influence of the higher centres which subserve mental processes as well as exercise control over those below them. The inhibition of the highest implies, as has been shown, the uncontrolled and exaggerated action of the lower or motor areas, for muscular relaxation or balance depend upon the equal functioning of the inhibitory or higher centres and the excitor or lower ones, in the same way as regular action of the heart depends upon the inhibition of the vagus balancing the excitation of the cardiac ganglia. The inhibition of the highest centres in hypnosis explains why the muscular movements and reflexes are exaggerated and at the same time unattended by consciousness. In the same way, the movements of a paralyzed limb, though they may be excessive, are not accompanied by psychical processes.

In the lighter grades of hypnotism there are psychical accompaniments, and the patient knows the limb is being moved, but is unable to prevent it, or can only do so by making great efforts. In the more advanced stages he loses all, or nearly all, sensation in the limb when it is moved by the operator, so that he often says that it 'seems to no longer belong to him.'

The analgesia of profound hypnosis is easily explained. It is sometimes more apparent than real, and then resembles that of incomplete narcosis. The subject suffers at the time, but on awaking has forgotten the circumstance. If hypnotized again and questioned, he will say that he felt the pain, but not sufficiently to cause him to shake off the lethargy which oppressed him. But in many cases there is absolute anæsthesia, and the

* *Lancet*, May 31, 1890.

patient is completely ignorant of what is being done to him. We know that anæsthesia may be produced in three ways—by acting on the arrangements of the highest centres, so as to cause cessation of their functions; by acting on the peripheral endings of nerves, and destroying their irritability; and by destruction or inhibition of the tract conveying sensation from the periphery to the brain. Chloroform acts in the first manner by setting up chemical changes in the brain cells, and hypnotism influences the same nervous arrangements by dynamic inhibition of the molecular activity of the cells. Cocain is an anæsthetic of the second class; and in poisoning by curara, and in the cutaneous anæsthesia of locomotor ataxy, we see the third cause at work. The anæsthesia produced by suggestion alone, as in the cases referred to on pp. 74, 75, can be explained by supposing that the centres of tactile sensation, which Ferrier localizes in the hippocampal region and the neighbouring temporo-sphenoidal convolutions, where also probably painful sensations are received (Lauder Brunton), are put out of action by some inhibitory action akin to that which obtains in the local anæsthesia so common in hysteria; and which probably proceeds from some irritation of distal origin, acting as an inhibitory influence. The sensation of pain is due to some condition of the cerebrum itself, and is caused by the arrival at the highest centres of intense afferent currents from the seat of injury. Liébeault supposes that in perfect health there is an equilibrium in the distribution of nervous force, which is upset in disease. Disease is accompanied by either excess or deficiency of nerve energy in the centres enervating the affected organs, and hypnotism enables us to check and correct this disarrangement. This theory is not without support, for we frequently see excessive and irregular action in one organ, associated with deficient action in others in the same subject. Centres are constantly discharging their energy through the most traversed channels, and nerve energy is being sent to the organs which have already absorbed most of it; *e.g.*, an

uncontrolled and excessive nerve influence is constantly being sent along the nerve tract concerned with the movement of a limb in hysterical contraction. Hypnotism may be supposed to act in such a case by enabling us, through suggestion, to divert or transform the nerve energy which is thus being misdirected. Whatever theory we may adopt as to the ultimate causation of the hypnotic state—and theories are almost as numerous as writers on the subject—we at least know that its phenomena are of subjective origin, and that they depend upon the inhibition and dynamogenesis of some centres, and the disconnection of others which ordinarily act in association.

How this disassociation is effected is of course a point of immense interest, and is in fact the crux of the whole matter. Its rationale must remain a matter of theory, as it depends on changes of the most subtle nature. But we know at least as much about the action of hypnotism as we do about that of many drugs which we use every day. It probably depends upon intracellular changes in the arrangement of molecules, whereby the discharge of nerve energy is prevented. The clogging of these molecules, and their consequent failure to respond to stimuli, through the ingestion of chloroform and other drugs, their excessive stimulation by coffee or small quantities of alcohol or opium, and their abnormal stimulation by belladonna or Indian hemp, belong to a different order of events. Natural sleep remains the closest analogue to hypnosis; but in sleep the inhibition extends to all the centres and their functions, and cannot be in part overcome by verbal suggestion; this is the important point of difference between the two states. Moreover, as we have seen, not only can the inhibitory influence be exerted in any direction we wish by verbal suggestion, but its correlative condition, dynamogenesis, can be treated in the same way. The rapid and even instantaneous induction of hypnosis in 'good subjects' can be explained by the setting up of a nerve habit, so that on the exhibition of

the accustomed stimulus the molecules fall at once into their former combinations. I have already said that for this reason we should be careful to make the exciting cause a combination of circumstances which would not be likely to occur spontaneously. The tendency of the sequence of events to repeat themselves on the application of the accustomed stimulus is often seen in hypnosis. If on the occasion of the first hypnotization the patient's arm has been fixed in a certain attitude at the moment the process was completed, it is very probable that the arm will spontaneously assume the same attitude at each subsequent sitting. In fact, the position will become an integral part of the process, unless the impression is removed by suggestion.

According to the school of Nancy, suggestion is the key to the whole position. By it the patient is hypnotized, and without it he lies like a log, inert in mind and body. By it, one centre can be made to act independently of others, and can be thrown into functional activity without the corresponding actions of those ordinarily associated with it. Thus, connections advantageous to the organism can be formed, and unfavourable associations can be modified or broken off.

The state of the subject lying passive and unacted upon by suggestion very closely resembles natural sleep. The breathing becomes slow and regular, the pulse slower and more full, the pupils contract and the eyeballs turn upwards. There is generally relaxation of all the muscles, as in sleep, and the arm, if raised, falls at once, unless retained in its place by suggestion. Ophthalmoscopic examination of the retina shows neither anæmia nor congestion. If a state of profound hypnosis is kept up continuously for several days or weeks, as has sometimes been done, changes are said to occur in the urine. The chief of these has been called 'inverted formula of the phosphates,' the relative proportion between the earthy and alkaline phosphates becoming changed. Dr. A. Voisin kept several patients who were subject to

periodic attacks of insanity in the hypnotic state for from fifteen to thirty days,* and he and Dr. Harant carefully collected and examined the urine passed before and during hypnosis. They found this inversion of proportion the only characteristic difference (*vide* table, p. 253).

But the amount of urea, fixed residue, and phosphoric acid were all slightly increased, thus justifying him in stating that in such cases the nutritive and eliminative functions were better performed in the hypnotic than in the waking state.

Voisin conducted these experiments in consequence of a paper read before the Académie des Sciences by Dr. Gilles de la Tourette, in which that opponent of the Nancy school stated the results of experiments he had made on some hysterical patients and on some subjects in Charcot's stages of hypnosis. He also found the ratio of earthy phosphates to that of the alkaline phosphates inverted from the normal proportion of 1 to 3 to 1 to 2, and sometimes 1 to 1. He moreover found the quantity of urea, phosphates, and fixed residue diminished in both hysteria and hypnosis as well as diminution in the quantity of urine passed, and he therefore concluded that the hypnotic state is a hysterical neurosis, and that it is attended with serious disturbance of nutrition. Here again we see the antagonism between the schools of Paris and Nancy, and in this case it would certainly seem that reason is on the side of Dr. Voisin, for whereas Gilles de la Tourette's experiment extended only over a few hours, that of Voisin extended, as we have seen, over weeks. The experiments of the former were, as is generally the case in Paris, made upon hysterical subjects who were hypnotized: it was therefore natural that the secretion should partake of the characters of hysterical urine. Dr. Voisin's figures also lose much of their value in consequence of his subjects being in a state of mental disease, so that experiments on healthy persons are wanted to decide this point.

And this brings me to the vexed point whether hypnosis is pathological, and a neurosis, as is contended by Charcot, or physiological, and even indicative of perfect mental health, as is asserted by Bernheim, Voisin, Forel, Déjerine and others. I have little doubt myself but that *le grand hypnotisme* of Charcot, when it occurs spontaneously, is a distinct neurosis of the hysterical type, and that many of the phenomena of advanced hypnosis are only obtainable in subjects of neurotic temperament. But that all people who have been hypnotized, or might be hypnotized, are hysterical or neurotic would be to so classify the great majority of mankind.

Dr. Buzzard says that most brain-workers and men of energy are more or less neurotic, and that the word should not carry the reproach with which it is sometimes associated. Even if most brain-workers are neurotic, I cannot so characterize agricultural labourers, soldiers, or sailors, and we know that among them are often found the best subjects for hypnotic experiments.

A most masterly and judicial exposition of hypnotism is contributed by Professor Tamburini of Modena, who impartially holds the balance between the theories of Bernheim and those of Charcot. He and Dr. Seppilli experimented on a hystero-epileptic patient, and published their notes on the case in 1882. At that time the important part now assigned to suggestion was not fully recognised, and in dealing with experiments made more than fifteen years ago one has to guard against the possible invalidation of the facts brought forward by unintentional suggestion. Tamburini, however, is positive on this point, for he approached the subject in a most sceptical spirit, and under the impression that the patient's unconsciousness was merely simulated. But he obtained all the phenomena described by Charcot at once, without difficulty, and without suggestion being possible. The further experiments of Vizioli, Grocco, and Lombroso in Italy fully confirm his results, and make it impossible to doubt that the stages described by Charcot are real somatic phenomena

occurring in certain individuals. Tamburini, however, traverses Charcot's assertion that such phenomena are characteristic of all cases of *le grand hypnotisme*, and contends that they are rare accompaniments of hysteria in hypnotized subjects of the hystero-epileptic type. Tamburini considers that these somatic phenomena are not obtainable in their entirety even by means of suggestion in ordinary hypnotized subjects, nor even in the majority of hysterical subjects. Hypnotism merely accentuates and brings into prominence the characteristics of the patient, both physical and psychical, whether they be undeveloped or suppressed. To enforce this theory, he cites cases where Charcot's phenomena have occurred in hystero-epileptic subjects in the waking state, just as in a few rare instances stigmata have been spontaneously produced without hypnotism. Hypnotism, by cutting off the life of relation, greatly facilitates the production of these accompaniments of extreme hysteria.*

He sums up the condition seen in the three stages as hyperexcitability of the nervous centres, which shows itself in different ways, according to the nature, intensity and duration of the stimulus applied. Hypnotism, in fact, increases the reflex excitability of the nervous centres, which is always abnormally present in hysterical persons, and in these cases it practically induces an attack of *la grande hystérie*, complicated with hypnotic phenomena. Tamburini therefore considers Charcot's stages as not characteristic of hypnotism, but as merely illustrating the only essential features of the condition, viz., increased susceptibility to suggestion and increased reflex excitability. The stages of hypnosis he considers as only a form of classification, such as we might adopt in speaking of the relative profundity of natural sleep.

It follows, from what he has written, that Tamburini refuses to regard hypnotism as pathological or a neurosis, but he considers it a psychical state, which may be induced in healthy persons, and which is as varied in its

* *Riv. Speriment*, vol. xvi.

manifestations as are the temperaments and constitutions of the subjects.

Braid found increased action of the heart with acceleration of the pulse, and he therefore warned experimenters to be careful with subjects in whom heart trouble was suspected. Tamburini and Seppilli, in their experiments on hysterical subjects hypnotized by the method of fixation, got similar results, which they have very carefully recorded. They found that in the stages of lethargy (Charcot), the tracing tends to rise progressively, whereas in catalepsy the reverse is the case. This shows that in the former state the vessels undergo dilatation, with consequent increased volume of the pulse, whereas in catalepsy they progressively contract. In somnambulism the condition approaches closely that observed in lethargy. The volume of the pulse augmented in the passage from the waking to the hypnotic state, and the changes indicated by the sphygmograph in the transition from one state to another, were instantaneous.

In the profounder states of hypnotism I have found nearly constantly present a tonic contraction of the capillaries and smaller arteries, so that wounds bleed less freely than in the waking state, and it is often possible—as is sometimes shown in platform experiments—to make a considerable puncture without drawing blood.

The phenomena observed in the respiratory sphere are exactly what we should expect. Tamburini and Seppilli find that when hypnosis is induced by fixation of the eyes disturbance of rhythm commences at once; and as long as the subject's attention is fixed it is quick and shallow, or it may even intermit or cease entirely for as long as a minute. But invasion of sleep is always marked by a profound inspiration. During lethargy the breathing is deep, becomes slower and slower, and tends to be accompanied by stertor. When catalepsy is induced by opening the eyes, there is an immediate arrest of respiratory movement—at whatever stage it has reached—and

this suspension may last a minute or longer. The breathing then becomes of peculiar character and rhythm, inspiration being slow, and expiration still slower. In somnambulism the character of the respiration partakes more of the character of that seen in lethargy, but is somewhat more irregular. During natural sleep, as in the waking state, there exists a rhythm between the movements of the chest and abdomen in respiration, but Gilles de la Tourette states that in hypnosis this rhythm is altered, and that the movements are no longer associated, and may even become antagonistic (Dict. des Sciences Méd., 'Hypnotisme'). In reading Gilles de la Tourette's writings on hypnotism we must remember that he refers to experiments on the most hysterical subjects, and it is well to bear in mind Preyer's warning against confusing *post hoc* with *propter hoc* symptoms.

Preyer remarks that the disturbance in the circulation and respiration noticed by some observers does not depend upon the hypnotic state, but is the result of the nervous stimuli used—whether visual, tactile, or auditory; and in support of this contention he maintains that persons in the waking state exposed to similar sensory stimulation will exhibit the same phenomena. They are, in fact, the result of inhibition of the respiratory centre, producing shallow and rapid breathing, and of the regulating circulatory centres, causing increased rapidity of the heart's action with heightened arterial tension from vaso-motor paralysis.

When hypnotism has been induced by simple verbal suggestion without any special sensory excitation, no such alteration of the pulse and respiratory rhythm is observable; and it is also seen after the patient has rested a few minutes in a state of hypnotic lethargy induced by fixation, that the breathing and pulse assume the character found in ordinary sleep. Tamburini, therefore, considers that the respiratory and circulatory symptoms observable in Charcot's stages of hypnotism are simply manifestations of the conditions characteristic

of this state—general increased muscular tonicity with ischæmia.

It would thus appear that the principal Italian investigators are fairly in accord as to the phenomena of

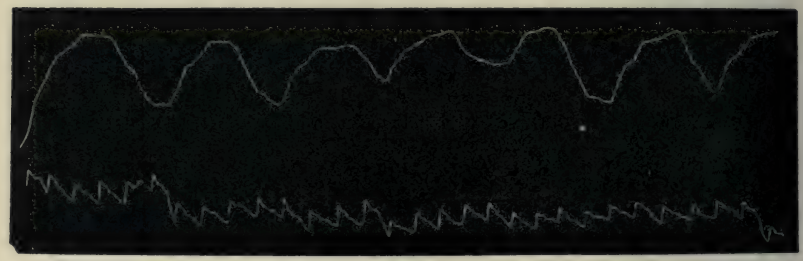

FIG. 1.

hypnosis, only that Morselli denies the possibility of Charcot's stages occurring spontaneously, while Tamburini asserts that he has seen them so occur in exceptional cases. I have not yet come across a case in which

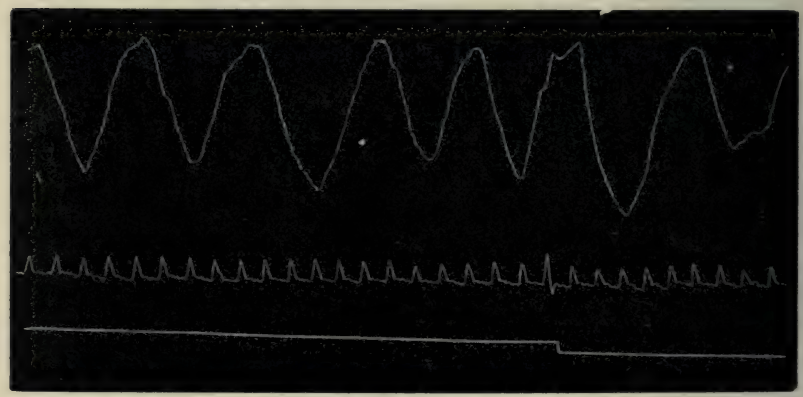

FIG. 2.

Charcot's stages have been producible, but I believe that such cases exist. Morselli's experiments are so full and graphic that I reproduce them as being thoroughly illustrative of the effect suggestion in the hypnotic state has upon the heart and respiration. My own experiments, as

far as they have gone, are thoroughly corroborative of them.

The subject of these experiments was a healthy young girl presenting no signs of hysteria, unacted upon by

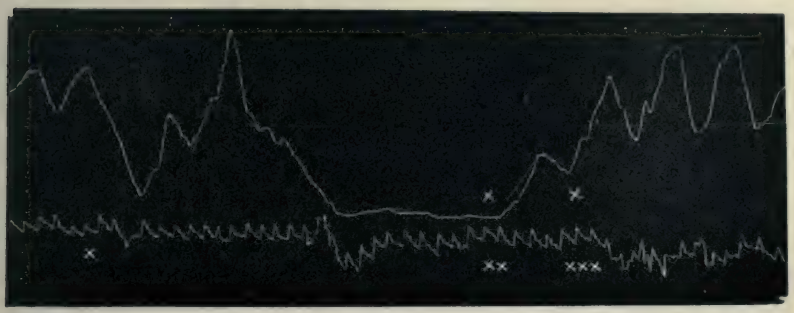

FIG. 3.

magnets, and not susceptible to Charcot's stages. She was always hypnotized by Professor Morselli or Dr. Tanzi by suggestion alone. From the first she fell into a state of profound trance, and was extremely susceptible to suggestion. The respiration was measured with Marey's

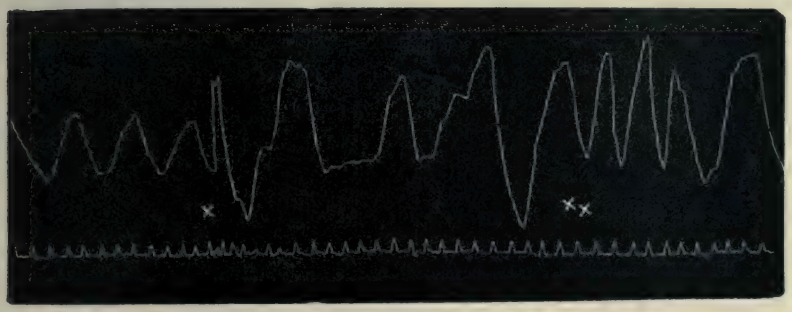

FIG. 4.

pneumograph, and the pulse with Mosso's aerosphygmograph.

Fig. 1 shows the tracings taken when the subject was awake and in her normal state. They show how the ordinary 'life of relation,' thoughts, ideas and impressions influence the rhythm and regularity of the functions.

Fig. 2 shows the tracings taken when the patient is lying tranquil and in a state of deep trance, unacted upon by the environment, and in a state of complete psychical repose.

In Fig. 3 the subject is told that she is to lift an imaginary weight. At × she raises it, and at × × she is told to put it down. The effect in the tracing is the same as if a real weight were being borne. There is the muscular contraction and preparation for the effort, followed by relaxation. This supports the theory that the idea is attended by motor accompaniments.

Fig. 4 represents the tracings taken when an attack of hiccough was induced by suggestion.

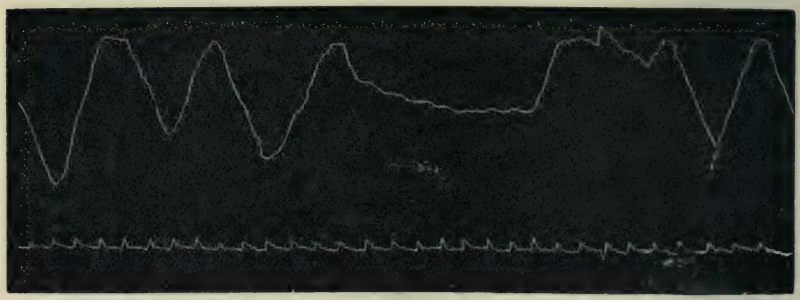

FIG. 5.

Fig. 5 represents the tracings taken when suggestions had been made leading up to a state of stupor, which the experimenters found a close reproduction of those observed in the idiopathic condition.

It is plain that the only characteristic symptoms of hypnosis in this case were slight increase in volume of the pulse and marked equalization of the respiratory curves. In fact, they are just what we should expect to find in a condition of absolute psychological repose. On the other hand, Charcot, Gilles de la Tourette, Tamburini, and others, as we have seen, describe marked changes in the phenomena of the circulatory and respiratory functions in the different stages of *le grand hypnotisme*.

Morselli found that by suggesting the symptoms he almost invariably and immediately produced the respiratory

curves and pulse tracings belonging to that condition, and he was even able to obtain the characteristic tracings of melancholia, mania, and other mental disorders.*

Preyer says that the rapidity of the pulse increases in some persons and diminishes in others, and directs that great care be taken to avoid error in gauging the blood-pressure. He finds that the pulse-rate frequently falls at first, but on the induction of catalepsy it becomes greatly quickened, and the radial artery is so compressed by muscular constriction that the pulse in it can hardly be felt. He also notices that the capillaries of the face are often very full during hypnosis, though sometimes there is pallor, or alternate pallor and flushing; but he thinks we should be wrong to infer from this that either anæmia or hyperæmia of the brain is necessarily present. Preyer finds that persons who have naturally very dry skins readily perspire in the hypnotic state, and that the head is especially affected in this way. I have very frequently been able to induce perspiration by suggestion, in persons who were in only the lighter grades of hypnosis.

Preyer found that after long hypnotic trance the chlorides and phosphates were greatly diminished; but the subject experimented on was markedly hysterical. It is but natural, however, to suppose that prolonged inactivity of the muscles and of psychical functions would be accompanied by greatly diminished waste and metabolism of tissue. Liébeault considers that hypnotic lethargy is a state similar to that assumed by hibernating animals, and he conceives it possible that organic life might be preserved for a very long period if the subject were kept warm and absolutely removed from sensory stimuli. He supposes that respiration would fall to eight, the pulse to thirty, and the excretion of urinary products to something very small. In the case referred to by Dr. Voisin, the patient was fed as usual, and, as has been seen, her excretions differed but little from the normal waking standard.

Alcoholism; 26. Nervous Exhaustion; 27. Extreme Anæmia; 28. Kleptomania; 29. Mischievous Morbid Impulse; 30. Agoraphobia; 31. Morbid Self-reproach.

In this chapter I propose to give an extract of cases successfully treated by hypnotic suggestion from the writings of Professor Bernheim and others. Most of the reports are much abridged from the originals.

Case 1.—*Aggravated Hysteria for a Year completely cured by Suggestion in Three Sittings.**

Madame X——, aged twenty-six; mother of two children. A lady of good constitution and lively temperament. She had not suffered from any symptom of hysteria until 1885,

* Bernheim, *op. cit.*, p. 399.

when an attack was brought on by some domestic trouble. From that time any annoyance induced a nervous crisis; otherwise she continued in good health.

Dr. Bernheim was consulted in October, 1886. The attacks had then increased in frequency and severity. They occurred about once a week, and were ushered in by a feeling of general weight and heaviness, and by a sense of constriction at the throat. These premonitory symptoms were followed by a deep sleep, which lasted from ten minutes to an hour. After this came general muscular tremors, which increased to strong convulsive movements, alternating with general rigidity, arching of the spine, etc. On this stage followed one of muttering and hallucinations, loud laughter and gesticulation. After the attack had lasted from one to two hours it passed off, leaving great exhaustion and *malaise*, with complete forgetfulness of what had occurred during the fit. On October 19 Dr. Bernheim was consulted; he examined her and found nothing organically wrong. He hypnotized her, and she at once fell into a profound sleep. He suggested while she was in this state that there should be a disappearance of the malady, and that it should not reappear. On October 21 and 23 she returned, and was again subjected to the treatment. There was no further need for suggestion, as the patient was cured and remained free from hysteria.

CASE 2.—*Hysterical Contracture of the Leg. By Dr. Dumontpallier (Physician to the Hotel Dieu, Paris).**

The following case presents so many points of interest, and so well shows the Nancy method of procedure, that I give it at some length:

The patient, a young girl of eighteen, was under the care of Professor Verneuil at the Hotel Dieu for hysterical contraction of the pelvi-trochanter muscles and of the flexors of the knee, dating from an attack of coxalgia

* Being portion of a clinical lecture, translated from the *Revue de l'Hypnotisme*, April, 1890.

some months previous. The limb had been forcibly extended under chloroform, and been kept in mechanical appliances for three months and a half without benefit, when Dr. Dumontpallier was called in to see her, and he thus describes her condition: There was general cutaneous and sensory anæsthesia of the right side, with paresis of the right arm; complete retention of urine, so that the catheter had to be passed several times a day; there were also hysterical symptoms, starting from the left ovary. The left side was normal in respect to sensation and muscular power, and menstruation was regular. The girl had had her first attack of hysteria two years before as the result of a fright, and from that time had been subject to various nervous troubles.

Dr. Dumontpallier determined to try the method of 'hypnotization by persuasion.' The patient was extremely nervous and apprehensive in consequence of the number of unsuccessful treatments she had undergone, and the doctor proceeded to soothe and quiet her as follows: 'My poor girl, you have endured a great deal of suffering, and you are in a very sad plight for one so young. You have a disorder of the nerves, but I shall be able to cure you, or at least to relieve your suffering, if you will do as I tell you and allow yourself to fall asleep: you will have no fear, but will feel quite at your ease, and when you awake you will find that you are better.' He then told her to look at him, and repeated several times 'Sleep, sleep, sleep.' Soon her eyes became humid, her eyelids fell, her eyes gradually closed, and in a few moments she passed into a state of somnambulism. She answered when spoken to, and the left side became as anæsthetic as the right.

Dr. Dumontpallier then made suggestions: 'The apparatus will soon be removed, and you will then find that you can move your toes, extend your leg, and turn from the right on to the left side; you will feel a desire to pass water, and you will ask for the chamber and be able to use it without difficulty. You will sleep an hour, and

when you awake you will recall to mind all the suggestions I have made to you, and this evening at the moment you fall asleep you will think of what has been done this morning.' Dr. Dumontpallier was careful to suggest that while the right side became well there should be nothing amiss with the left side, as he feared 'transfer' might otherwise take place. On returning to the ward the next day he found that the patient had awakened at the end of an hour and had asked for and used the chamber. The catheter was not again used, and at night she slept on the left side for the first time for several months.

The girl was hypnotized daily, and steadily improved without having any relapse, until on the fourth day the apparatus was removed and she was able to sit up in a chair and move her leg.

In a few days more the patient was able to walk, and the atrophy of the long-disused muscles began to disappear with exercise and massage.

CASE 3.—*Hysterical Aphonia for Two Months, rapidly cured by Suggestion.**

Madame C. L——, aged thirty, has been hysterical since girlhood. On January 15, 1884, having been voiceless for two months, she consulted Dr. Bernheim, who first applied electricity to the throat externally, affirming the while that it would cure her. As that, however, had no effect, he hypnotized her, and at once induced a profound sleep. He suggested to her while she slept that her voice should return, but on awakening her he found no improvement. The second and third séances were equally unsuccessful. At the fourth she slept more heavily, and Dr. Bernheim was able to make her say she expected to be cured in eight days† (the following Tuesday). He continued to hypnotize her daily, and each day he caused

* Bernheim, *op. cit.*, p. 427.

† In many cases it is most important to get the patient to fix a time for his cure; the idea becomes deeply implanted, and in hysterical cases it is generally realized. Of course, the sleep must be very profound to make this possible.

her to repeat that she was to be cured on the Tuesday. When that day came she was quite unconscious of having made this prophecy, she was still voiceless, and was hypnotized as usual. Dr. Bernheim told her she must speak when he awoke her, and impressed her strongly with this idea. On arousing her she said in a feeble voice, 'I think I can speak now.' The voice became gradually stronger, and by the evening was restored to its normal quality and volume. Dr. Bernheim gives many other cures of hysterical aphonia, several of them after one séance.

CASE 4.—*Choreic Movements of the Hands and Inability to Write, cured by Hypnotic Suggestion.*

Victorine L——, aged twelve and a half, of lymphatic temperament and good constitution, affected with chorea of the right side. It appears that when she was four and a half years old she suffered from general chorea, brought on by fright. It was a very severe attack, as she could neither walk nor talk, and had a great difficulty in eating. It lasted three months. A second attack of the same kind came on when she was seven and a half. She was attacked a third and fourth time at intervals of two years. In the fifth attack she was brought to Dr. Liébeault for treatment. It commenced on May 27, and on that day she had seven very violent fits, on the 28th and 29th the same number, and then she was hypnotized for the first time. Afterwards, in the afternoon, she had two fits slighter than the preceding ones. On May 31 again hypnotized. On that day she had one fit, and then no more until June 9, when she returned to be treated for a relapse brought on by fright. Professor Beaunis happened to be at the dispensary, and he got the patient to attempt to sign her name. In spite of much effort, the child—a very intelligent and docile little girl—completely failed to make any distinguishable letter on the paper (Fig. 6). Dr. Liébeault hypnotized her, and while asleep she was directed to write her name. The result was fairly legible and she wrote without

hesitation or trembling. She was soon awakened, and again told to write. Without difficulty she at once wrote her name and address in very creditable style (Fig. 7).

FIG. 6.

For the next few days she continued under observation and treatment, and was then discharged perfectly cured.

FIG. 7.

Professor Beaunis says he makes no remarks on this case, as the handwriting appeals more than words can to an unprejudiced mind.*

* Beaunis, *op. cit.*, p. 236.

CASE 5.—*Hysteria, Sleeplessness, Want of Appetite, Tremors, Depression of Spirits, cured by Suggestion in Two Sittings.*

Mademoiselle X——, aged twenty-seven, an intelligent lady who had enjoyed good health and spirits, and was free from hysteria until August, 1885; at that time she had a disappointment which changed everything.

In February, 1886, she consulted Dr. Bernheim. She had then suffered for months from complete want of appetite, sleeplessness, giddiness, especially on lying down, terrible dreams when she did sleep, and slight muscular tremors in the limbs, so that it was not easy for her to keep her hand steady. She had been treated with bromides and antispasmodics without success. He hypnotized her, and she slept easily and profoundly. He suggested the disappearance of all her troubles, and after two séances all the morbid symptoms had disappeared, she slept well, and ate with appetite. Her spirits were as good as ever. Dr. Bernheim adds that she remained well.

CASE 6.—*Intermittent Pseudo-Paralysis of the Lower Limbs, with Convulsive Trembling of the Legs for nearly Four Years, cured by One Hypnotic Suggestion.*

Madame S——, aged twenty-six. After much domestic trouble and a bad miscarriage, this lady completely lost the use of her lower limbs for three months. The paralysis disappeared as suddenly as it came, but returned again in a few weeks. These intermissions and relapses followed each other every few weeks, up to the time Dr. Bernheim saw her, for nearly four years. She had undergone all kinds of treatment—including electricity and massage—at the hands of the most eminent neurologists of Paris, but nothing seemed to shorten the terms of paralysis or to avert them. On May 29, 1887, Dr. Bernheim was sent for to Paris to see her. He found her perfectly free from the ordinary symptoms of hysteria, in good general health without any organic disease, and

unusually bright and intelligent. While lying down she was able to move the legs perfectly well, but when Dr. Bernheim made her attempt to stand, she at once collapsed, and would have fallen to the floor had she not been supported. On moving the legs they were seized with tremors, over which she had no control.

He found the reflexes normal, and all the functions perfect.

On being hypnotized she fell into a light sleep, during which she was conscious of everything going on around her. On being aroused she denied having been at all influenced. Dr. Bernheim, while she was in the hypnotic state, moved the legs, and assured her she would be able to stand and walk quite well when he told her to try.

After the operation he insisted on her making the attempt, and, to her surprise, she was able to both stand firmly and walk with confidence.

He hypnotized her again the next day, when she fell into the third stage of sleep, and the suggestions were repeated.

Madame S—— had been suffering from the present attack for six weeks when Dr. Bernheim was called in. He had opportunities of seeing the patient at intervals afterwards, and there was no relapse.*

CASE 7.—*Writer's Cramp for Three Years; Rapid Improvement; Temporary relapse; finally cured by Suggestion.*

H. C——, aged forty-seven, an accountant, consulted Dr. Bernheim, November 18, 1885. He was healthy and strong, and in no wise nervous or hysterical. Three years before he began to feel symptoms of the malady. After writing a few lines all the fingers became contracted, and he had to desist for a time. At first he was able to write again after a short rest, but gradually the cramp became worse, so that he was unable to sign his own name. By means of various devices he contrived to go

* Bernheim, *op. cit.*, p. 457.

on a little longer, but at the time he consulted Dr. Bernheim he had been compelled for three months to write with his left hand. He was hypnotized, and at once fell into the third degree of sleep. Dr. Bernheim suggested the disappearance of the cramp. On awaking he was able to write two lines and a half without cramp. The next day he wrote eight lines without cramp.

On November 21 the patient was able to write a business letter, and only complained of feeling heaviness in the wrist, and a slight tendency to flexion of the fingers.

On November 24 the improvement was still maintained, and Dr. Liébeault took charge of the case during Professor Bernheim's absence for two months. In the middle of December a relapse took place, and the patient again became unable to write more than a few lines. He left off treatment until January 29, when he again consulted Dr. Bernheim. Improvement now rapidly set in, and progressed until, on March 2, he finally discontinued treatment, being perfectly cured. He has gone back to his office, and writes all day long without fatigue or cramp.*

CASE 8.—*Rheumatic Pains in the Shoulder-joint for Three or Four Months, completely cured in Two Sittings.*

Emile L——, aged sixty-one, a glass-maker, consulted Dr. Liébeault, November 30. He had never suffered from rheumatic fever, but nine years before had had sciatica for three years.

When seen, the pain was in both the shoulders, but especially the right one, at the place where the collar-bone articulates with the scapula. There was also a tender spot above the anterior superior spine of the ilium on the left side. It was most felt on stooping. Besides all this there were pains in both knees. The patient was hypnotized, and fell into a light sleep. On awaking the pains in the knees were gone, and those in the shoulder were much better. He had been unable for three weeks to dress himself, but now he was able to do so.

* Bernheim, *op. cit.*, p. 486.

On November 3 he was again hypnotized, and again slept lightly. He awoke perfectly cured, and remained so.*

CASE 9.—*Articular Rheumatism for Three Months, cured by Suggestion in Two Days.*

Jeanne M——, aged seventeen, consulted Dr. Bernheim, August 3, 1887. She was brought to a hospital in a carriage, and into the consulting-room supported with difficulty by two persons, being quite unable to stand alone. She was lymphatic, pale and thin, and had had an attack of hysteria brought on by chagrin some months before.

Since May she had suffered from subacute rheumatism, which had gradually and steadily become worse.

Dr. Bernheim found that both wrists were extremely painful, but not swollen. The first joints of the fingers were greatly swollen and acutely painful on pressure. The left knee was slightly swollen and very tender. There was also pain below the right ankle and in the joints of the toes. The spine was tender on pressure.

There was also amenorrhœa, leucorrhœa, and sleeplessness. The patient was hypnotized and fell into a sound sleep.

On August 6, after two sittings, she felt very much better. She slept well, had a good appetite, and had hardly any pain. The swelling of the joints had almost entirely disappeared, and there was only tenderness on pressure. She was again hypnotized, and the suggestion made that she should feel no more pain.

On August 8 she returned completely well and cured of all the symptoms, was able to walk perfectly and without any pain, and was altogether a changed person.†

* Bernheim, *op. cit.*, p. 539.
† *Ibid.*, p. 544.

CASE 10.—*Neuralgia of the Fifth Nerve for a Year, with Tic-douloureux for a Month; Rapid Improvement and Cure in Ten Days.*

Charles X——, aged sixty, entered the hospital July 27, 1885. His trouble had commenced a year before with pain in the right side of the nose. The pain came on several times a day, and lasted from a few minutes to several hours. Since four weeks the pain had spread to the eye, the forehead, and all the right side of the face. It was very acute, and came on in paroxysms every hour or two, and lasted about half an hour. In the intervals there was no pain, but only a feeling of burning. There was lachrymation during the attacks, and they were also accompanied by convulsive movements of the face.

The patient was strong and well otherwise for his age. Dr. Bernheim found the points of exit of the branches of the fifth nerve sensitive to pressure, and all the right cheek tender to the touch. On July 28, the first attempt to hypnotize him was unsuccessful; but on July 30 he was successfully operated on, and when he awoke he felt much better. In the afternoon he had paroxysms of pain, but less intense, and he slept better that night than he had done for weeks.

He was hypnotized about every second day until August 9, by which date he was perfectly cured, and he remained well.

CASE 11.—*Sciatica for Seven Weeks, cured by Suggestion in Six Days.*

Joseph L——, aged forty-four, shoemaker, was admitted into the hospital under Dr. Bernheim, May 15, 1885. He was a weakly person of lymphatic temperament and with emphysema. He had continual pain along the course of the sciatic nerve of the left side, and this was everywhere painful on pressure, aggravated by sitting, and especially by lying down in bed. The leg felt heavy and numb, and

the pains, which were pricking in character, radiated from above downwards.

On May 20 he was hypnotized, and fell into the third degree of sleep. He felt better on awaking, and the curative suggestions were repeated daily until the 26th. Each day he became better, and in a week was perfectly cured. He had previously been treated with medicated baths at the hospital for three days without much effect.*

CASE 12.—*Nocturnal Enuresis from Infancy, cured by a Single Suggestion.*†

Jacob S——, aged seventeen, of weak intellect, but strong and healthy, had always suffered from the above complaint. He had control over the functions during the day, but nearly every night he suffered from incontinence.

He consulted Dr. Bernheim, December 28, and was hypnotized with great readiness. Suggestions were made to him while in a state of profound hypnotic sleep that he should awake several times in the night and leave the bed.

He returned to the hospital, but required no further treatment, for the malady was at once cured, and did not reappear.‡

CASE 13.—*Amenorrhœa; Suggestion that the Function should reappear on a Certain Day; a Successful Result.*

Mademoiselle C——, aged twenty-five, teacher, consulted Dr. Bernheim November 17, for the above-mentioned trouble. She had seen nothing since October 7, and in consequence she felt distended, a sense of constriction round the waist, and other symptoms referred to the same cause. She was a regular patient of Dr. Liébeault's, and she readily fell into a profound sleep. Dr. Bernheim suggested that

* Bernheim, *op. cit.*, p. 548.

† *Ibid.*, p. 495.

‡ All practitioners of suggestion agree that the system is almost specific in the treatment of this troublesome complaint uncomplicated by organic defects.

the function should be re-established on November 30, and made the patient repeat the suggestion after him.

On November 30 she came to tell him that it had happened as he suggested. He hypnotized her again, and suggested December 28 for the next period. This also was realized.*

CASE 14.—*Menorrhagia about every Twelve Days; altered by Suggestion to Twenty-eight or Twenty-nine Days, and finally cured.*

Madame H——, aged thirty-five, mother of three children, the youngest of which is nine years old. Hysterical, but of good constitution. Before she had had children the period used to come on every three weeks, but for two years it had returned about every twelve or fourteen days, or even at shorter intervals. It was accompanied by pain and hysterical troubles, and was very copious. The patient readily fell into a profound sleep, and Dr. Bernheim suggested that the next period should not come on until October 9, should only last three days, and should not be accompanied by any pain.

September 27: This was the fifth séance, and the sixteenth day since her last period. She felt premonitory symptoms of its return—such as headache, and pain in the back. These symptoms, however, passed off, and by means of suggestions repeated every second day the period was retarded until the night of October 6 and 7, or twenty-six days. *This was the first time in her life that there had been more than twenty-one days' interval, and the first time for two years that it exceeded sixteen days.* It lasted three days, was unattended with pain, and was less copious than usual.

On October 18 Dr. Bernheim recommenced hypnotic treatment, and suggested that the next period should be on December 4 or 5, and henceforth every four weeks.

* Bernheim, *op. cit.*, p. 557.

It appeared at the end of twenty-four days. The treatment was continued until the following May, by which time the function was thoroughly regulated, and occurred every twenty-eighth or twenty-ninth day, without pain or other abnormal symptoms. During the treatment a number of nervous and catarrhal symptoms disappeared.*

CASE 15.—*Partial Paralysis of the Left Side for Eight Days; rapid Improvement under Suggestion, and almost Complete Cure in Three Weeks.*

Louis C——, aged sixty, house-painter, was taken into the hospital November 7, 1886. He had enjoyed good health until six days before, when he had suddenly felt a sensation of weight in the left leg. He returned home, and two hours later felt the same sensation in the left arm, accompanied by a pricking, which still continued when he entered the hospital. In the evening he was no longer able to use his left leg.

Dr. Bernheim found the temperature and pulse normal, the arteries atheromatous and rigid. The features deviated markedly to the right. The patient sat up in bed with difficulty, and was unable to fully raise his left arm, which was also weak and easily tired. He was unable to stand. When lying down he was able to raise the left leg, but could not keep it up for more than four or five seconds. The reflexes were diminished, and he was unable to bend the instep. Sensibility normal. Constipation for four days, for which he was given an enema.

On November 9 the patient was hypnotized, and fell at once into a profound sleep. On awaking he was able to hold up the left leg for ten seconds, and to bend the toes better.

* Bernheim, *op. cit.*, p. 560. The effect of imagination and emotion in modifying the renal, alvine, uterine, lacteal and other secretions is so well known, that the striking results produced by hypnotic suggestion in their functional disturbance is not to be wondered at. In 'Carpenter's Physiology' (*loc. cit.*) numerous examples are given.

He was hypnotized the 11th and 16th, with only slight effect. On November 17, after the suggestion, he was able to stand alone, and to walk with very little assistance.

On November 19 he was able, after being hypnotized, to walk the length of the ward without help. He could hold the leg up when lying down for an indefinite time, and had quite regained power over it. The reflexes were slightly increased.

He progressed steadily every day, and was able to walk downstairs on December 2. He still, however, felt a heaviness in the arm and leg, which prevented his using the brush or climbing ladders so well as formerly.*

Professor Bernheim fully describes 105 cases of many kinds of disease treated by hypnotic suggestion. Among these are several examples of grave cerebral and spinal disease, in which the treatment seemed to prolong life, and of which it certainly relieved the suffering.

Examination after death often revealed a great amount of disorganization, so that it seemed extraordinary that any treatment could bring about much improvement. He explains the good effects which attend suggestion, even where there has been extensive hæmorrhage into the brain tissue followed by atrophic changes, by insisting that in disease of the nervous centres functional derangement often exists quite out of proportion to the actual lesion; *i.e.*, hæmorrhage may destroy a portion of the brain substance, and this may react on the neighbouring zones by setting up sympathetic irritation.

Neither suggestion nor anything else can, of course, do anything to restore the disorganized brain tissue; but it is all-powerful, he observes, in the treatment of the sympathetic and functional troubles which accompany such a condition (*op. cit.*, pp. 308-324).

CASE 16.—*Aggravated Hypochondriasis.*

M. F.——, aged forty-three, has suffered for a year from this malady. She is conscious of all her internal

* Bernheim, *op. cit.*, p. 342.

organs, and their functions cause her painful and distressing sensations, which makes her think that they are all more or less diseased. She has lost all hope, and is persuaded that she will never recover. She is debilitated and suffers from indigestion, does nothing but lament and analyze her sensations, lives in a perpetual state of agitation, and does not sleep.

She was put under suggestive treatment, and fell into a light sleep. By its means sleep was restored, digestion re-established, and, above all, her attention was gradually diverted from her sufferings, real and imaginary, and in a few weeks she was cured.*

CASE 17.—*Hysteria, Tendency to Tetaniform Spasms, Insomnia, Morphia and Chloral Habit.*†

Madame K—— was admitted for treatment, suffering from the above conditions.

Hypnotic treatment combined with suggestion was employed to combat them. The narcotics were gradually discontinued, the spasms ceased, the natural sleep was regained by degrees, so that she was dismissed cured.

Braidism was tried without suggestion at first, but it only aggravated the symptoms.

CASE 18.—*Moral Depravity in a Boy; cured by Suggestion.*‡

On June 9, 1888, M. F——, a youth aged sixteen, was brought to Dr. Voisin at the Salpêtrière. From the age of six or seven he had been incorrigible. Not only did he tell lies, steal, play truant, and behave ill generally, but he also tried to corrupt all the children with whom he came in contact. He became worse and worse as he got older, and was turned out of several institutions into which his mother had procured his admission. (Dr. Voisin describes some of his vices, which are unfit for repetition,and which

* Dr. Burckhardt, superintendent of the asylum at Préfargier, *Revue de l'Hypnotisme*, August, 1888.

† *Ibid., loc. cit.*

‡ Voisin, *Revue de l'Hypnotisme*, November, 1888.

prove the youth to have been utterly depraved and bad.) On examination he was found to have an internal squint of the left eye, nystagmus, and haziness of the cornea. The tongue deviated to the left. Otherwise he was well made and healthy. He read with difficulty, and was very ignorant, though his memory and power of observation were sufficiently good.

Dr. Voisin endeavoured to hypnotize him, but was not successful until the third séance. Once asleep, suggestions of moral reform were made.

He began to improve at once, and by July 6 the youth was absolutely transformed. The wish to do evil first disappeared, and was then replaced by a desire to do right. His insubordination and disobedience had given place to a wish to please his mother. He expressed to Dr. Voisin the happiness he felt at being thus changed. He saw the doctor again on October 6, six weeks after the discontinuance of the treatment, and the cure was maintained.

Dr. Bernheim and Dr. Liébeault give several instances of cures of moral diseases. The former, after describing a somewhat similar case to the above, asks if he can be accused of tampering with the child's free-will because he has repressed his bad qualities (*op. cit.*, p. 357).

Dr. Kingsbury publishes two cases of moral obliquity in children which he has treated and cured by hypnotism (*op. cit.*, p. 191).

Cases contributed by Dr. Van Eeden, of Amsterdam.

Case 19.—*Neuralgia of the Neck and Left Shoulder; Paralysis of the Left Arm and Leg, of Syphilitic Origin.*

A. H——, aged thirty-four, is a strongly-built man, with an originally good constitution. He became infected eight years ago. Thirteen months ago he was suddenly attacked with total loss of power in the left arm and leg.

On October 9 he consulted Dr. Van Eeden, and was

then suffering from severe pain in the neck and left shoulder, which had lasted two months. The pain prevented his sleeping more than an hour or two at night. He had partially recovered from the paralysis, but for five months no progress had been made. He was unable to fully raise the left arm, to open the hand or extend the fingers. Antisyphilitic treatment had produced no effect for some months.

The patient was hypnotized in the usual way, and the second degree of somnolence (slight catalepsy) was produced. While in the hypnotic state suggestions were made to lessen the pain, and the rigidity of the semi-paralyzed limbs was relaxed by suggestions and active and passive movements. On awaking, the pain was found to be much relieved, and at night he slept for hours.

The treatment was continued daily for six weeks. By October 12 the pain had entirely disappeared, and he enjoyed eight hours' sleep every night henceforth.

Movements were constantly employed during the hypnotic state, and power gradually returned to the limbs, so that by November 8 the patient could extend all the fingers of the left hand, and keep the arm in a horizontal position for a considerable time. When treatment was discontinued after six weeks, he could make all the movements of the arm and hand freely. His walking power had also greatly increased.

CASE 20.—*Cephalalgia, Gastrodynia, Dyspepsia.*

The patient, a little girl of eight, is a delicate child, and has suffered from continuous headache, want of appetite, and pain in the stomach. She rises nearly every day with a bad headache, and twice or thrice a week she is obliged to stay in bed on account of the pain. The stomach pains occur irregularly, last only a short time, and are very severe. She never has had a good appetite. Once only has she been free from pain—about three years ago, for a fortnight.

On September 16 the child was hypnotized by Dr. Van Eeden for the first time. The sleep produced was profound, as is usual with children. In the first sitting the pain was quite removed by suggestion, and did not return for two weeks, though there was only one consultation. Since September 16 she has only twice had headache, and this was each time at once removed by suggestion. The child remains under treatment, as such cases necessarily require a long course. There has been no pain in the stomach since her first visit, the appetite is better, and the child's general health more satisfactory than it has been for years.

CASE 21.—*Chronic Alcoholism.*

M. G——, a well-to-do man of forty-nine had for sixteen or seventeen years constantly drunk alcohol to excess. He has never during all that time given it up. On his best days he has only taken four to eight glasses of cognac, but mostly he has drunk twenty or more. He has had several attacks of delirium tremens, and his mental faculties are much deteriorated. He is unable to apply himself to any business requiring thought or attention, and is unable to write his name. His face is covered with pustules of acne.

On September 27 he was hypnotized, and fell into a light sleep. Dr. Van Eeden suggested disgust for stimulants and increased strength of will. During the sleep the patient was persuaded to promise solemnly to leave off alcohol. He was also treated with arseniate of strychnia, 4 to 8 milligrammes daily.

The treatment was continued daily for a week, then once a week for two weeks. After that no further suggestion was needed. From the time of the first sitting the patient took not a drop of alcoholic liquor, and though offered wine he refused it. Some restlessness and malaise were felt the first week. On October 4 he was able to write his name and to resume his business. Now (after two months) he feels quite well and strong, and is confident of being able to keep his promise. The acne is

cured, and he sleeps and eats well. He continued to visit Dr. Van Eeden from time to time as a precaution.

In communicating these cases Dr. Van Eeden says 'they are selected from many similar ones. My results are the best in the treatment of various nervous diseases, but the cases are too long to report. I may add that according to my own experience the effect of psychical treatment is best seen in the following diseases: Neurasthenia, nervous debility, enuresis nocturna, slight or incipient brain troubles, morphia habit, alcoholism, bad habits in children, hysterical paralysis, nervous dyspepsia, anæmia, stammering, chorea, sleeplessness, nervous asthma. Combined with systematic movements during the hypnotic sleep, the treatment is of effective service in paralysis caused by apoplexy or embolism, and in infantile paralysis (acute anterior polio-myelitis), if not of too long standing.'

Drs. Van Renterghem and Van Eeden contributed a valuable paper to the International Congress on Hypnotism held in Paris, 1889.* In this they give very fully the results obtained in their clinique in nearly 500 *consecutive* cases. Many of these cases were not of a nature to benefit by any treatment, and most of them only came into these doctors' hands after other methods had failed. The reader of this paper must be favourably impressed by its candour and impartiality, and by the evident absence of exaggeration, which often seems inseparable from the advocacy of a new treatment, and which is certain to prejudice the professional mind against it. They attach much importance to the presence of a favourable environment and to the observance of minutiæ. They contend that by suggestion in the hypnotic state they can restore the balance of health by suppressing morbid action and by developing the *vis medicatrix naturæ*. They seek only to obtain the lighter grades of hypnosis in order that

* *Comptes Rendus*, Octave Doin, Paris, 1890.

there may be no possible interference with the patient's free-will or individuality.

Drs. Van Eeden and Van Renterghem have practised treatment by suggestion among the upper and middle classes of Amsterdam for three years, during which time they have applied the system in several hundred cases. They were both previously for many years in ordinary practice, and their testimony to the value of hypnotism and suggestion is therefore of great value.

In dipsomania they have been very successful, and also in the treatment of bad habits and perverted instincts.

In affections of the genito-urinary organs they have achieved good results, and also in many forms of dyspepsia and intestinal trouble. In morphinomania they have been successful when they have produced somnambulism.

Like all physicians who have tried hypnotic suggestion in rheumatic affections, they express themselves pleased with the results, and they attribute the beneficial effect partly to the relief of subjective symptoms, such as pain, which depress the vitality, and partly to the regulative action it exercises over the circulation and secretions. They mention an interesting case of hystero-epilepsy and spontaneous catalepsy of several months' duration initiated by the experiments of a public lecturer on hypnotism. The young man was speedily cured by a course of medical hypnotism.

From August, 1887, to June, 1889, they treated 414 persons by hypnotic suggestion—219 men and 195 women. In respect to their susceptibility they found as follows: Uninfluenced, 15; light sleepers, 217; profound sleepers, 125; somnambulists, 47. As regards results they give the following figures: 53 discontinued treatment after the first or second visit, 71 were not improved, 92 improved, 98 greatly improved, and 100 were cured.

They agree with Dr. Forel that every person in sound mental health is susceptible to hypnotism under favourable conditions. The difficulty being to discover the conditions necessary in each individual case, therein lies the

opportunity for exercising the physician's tact and *savoir faire*.

Their success has been chiefly with the neuroses, but they give particulars of several cases of organic disease which have been benefited or cured. Among these are one case of right hemiplegia with asphasia of three months' duration (cured); four cases of hemiplegia (much improved); one case of paraplegia with loss of control over the sphincters (cured). In two cases of Bright's disease they effected great improvement, and suggestion seemed to stimulate the kidneys and relieve the œdema. In many of the slighter forms of mental disturbance they have been very successful. In epilepsy they have been unable to do much good.

CASE 22. — *Neurasthenia with Deficiency of Saliva and Constipation for Thirty-five Years, cured by Suggestion.**

Madame V——, aged fifty-five, consulted Dr. Burot in August, 1888. She had for many years carried on the business of weaving hemp, and it had been her habit to moisten the thread with the saliva. When about twenty years of age this secretion showed signs of drying up, and at the same time obstinate constipation appeared. She lost her appetite and became anæmic, constantly drowsy, extremely weak and feeble, and altogether a confirmed invalid. At forty the change of life occurred, but it made no improvement in her health, which became worse and worse.

Dr. Burot found her suffering from pains all over the body, general malaise and anæmia. The tongue was red and dry, with prominent papillæ. There was great dryness of the mouth, very deficient digestion, and obstinate constipation. The stools were infrequent, and their passage caused intense pain. The dryness of the mouth often prevented sleep. Dr. Burot hypnotized her and suggested increased flow of the digestive secretions, and

* Reported by Professor Burot, of Rochefort, *Revue de l'Hypnotisme*, December, 1888.

at the same time gently rubbed the salivary glands and the abdomen.

After a month's treatment the patient was cured. The mouth became moist, the saliva abundant, digestion easy, and the bowels regular and comfortable. At the same time the general health was re-established, and she grew stouter and quite strong.

Case 23.—*Confinement.**

Professor Ramon Cajal, of Barcelona, reports a case in which he abolished the pains of labour, without in any way weakening the power of the uterine contractions, by hypnotic suggestion. The woman had been frequently hypnotized previously, and was the mother of five children. The labour was extremely rapid (occupying less than half an hour) and was quite painless. On the fifth day she resumed her household duties, and in a fortnight was quite well. Her previous confinements had all been tedious.

Case 24.—*Functional Dumbness with Melancholy, cured by Suggestion.*

J. D——, aged thirty-six, was born of healthy parents, and was well and strong until her twenty-fifth year, when she fell suddenly ill. After a violent attack of hysteria, during which she uttered piercing cries, she became gradually perfectly dumb, then indifferent to her surroundings, and finally extremely feeble in body. After a course of treatment at a spa her health became re-established, but she remained mute in spite of all attempts to make her speak.

This condition had continued for ten years when Dr. Velander first saw her. She heard and saw perfectly, but she made no attempt to utter a sound, and she was also in a state bordering on melancholia. He hypnotized her, and she at once fell into a state of profound somnambulism.

* Reported in *British Medical Journal*, October 9, 1889.

In this state he tried in various ways to make her speak, but her lips never moved until, after an hour of fruitless effort, he ordered her to open the mouth, and he manipulated the tongue with a considerable degree of force, and told her he had broken the strings which tied it and that she could speak.

After a few minutes' friction of the temples she actually did utter a few words in a faltering and husky voice. She returned for treatment daily, and in two weeks, Dr. Velander says, he had the pleasure of sending her home perfectly cured, not only in speech but in spirits.*

Dr. Velander reports having treated over 600 cases by the Nancy method, and testifies to his satisfaction with the results. His experience tallies with that of other observers, for he finds it most successful in pains in general, neuralgia, sleeplessness, incipient melancholy, dysmenorrhœa, amenorrhœa, incontinence of urine, sleep-walking, acute and chronic rheumatism, nervous amblyopia, vicious habits, and dipsomania.

CASE 25.—*Functional Paraplegia, and Hemianesthesia, treated by Suggestion.*†

The patient had had a fall, and as a result had been paralyzed for twelve months. The legs were flaccid and absolutely powerless, and the nurse always had to arrange the feet. The muscles were so atrophied as to be hardly distinguishable.

The patient on being hypnotized at once fell into a profound sleep. While in this stage the leg was raised in a horizontal position, and the suggestion made that it must remain so. It remained extended for a few moments, and thus afforded evidence of the functional nature of the disease.

Suggestions of ability to stand, raise the legs, cross them, etc., have resulted after ten sittings in power during the waking state to lift the legs together, cross one leg over

* Dr. Velander, of Yonkoping, Sweden, contributed a report of this case to the congress.

† *Boston Medical and Surgical Journal*, June, 1890.

the opposite knee, and to stand easily for a short time. The chronic constipation has yielded, and the spinal pains, which were very troublesome, have disappeared.

The urine was formerly retained, but the retention was much relieved. The leg muscles greatly increased in size, and became firm under the touch. The patient was made to repeat the suggestions after the physician, and this plan was found to increase their efficacy.

Dr. Osgood in referring to this case later, says that the improvement has been maintained, and that the patient can now walk.

CASES 26 TO 29.—*Four Cases of Epilepsy, treated by Dr. Edgar Bérillon.**

1. M. N——, aged thirty-five, has had frequent fits, occurring almost without warning, so that she has often fallen in the streets. The attacks have been violent, and during them she has foamed at the mouth and has bitten her tongue.

After hypnotic treatment the fits ceased and did not reappear for twelve months. Then she had three attacks one after the other, and she again applied for treatment. She was again hypnotized, and up to the time of the report (two months) she had had no relapse.

2. Madam A——, aged twenty-eight, came under treatment. Since twelve years of age she had wetted the bed at night, and at seventeen she began to have nocturnal crises during sleep. In the course of these attacks she used to foam at the mouth and bite her tongue. Her husband said that her sleep was disturbed by nightmare, and that she ground her teeth. When she became enceinte she had violent attacks of convulsions. When she came under treatment, the skin of her chest, arms, and hands presented numerous marks of vitiligo. The patient had been under treatment at St. Anne's for five years, and had taken large quantities of bromides without benefit.

Two months of suggestive treatment completely altered

* *Revue de l'Hypnotisme*, October, 1890.

all these symptoms. The nightmare and grinding of the teeth disappeared, she lost the stupid and indolent aspect she wore before the treatment, and became bright and intelligent-looking. At the same time the vitiligo disappeared by degrees. The cure had continued up to the time of the report (five months).

3. J. S——, a youth of eighteen, of neurotic constitution and family, had suffered from choreiform movements in his limbs, and especially his arms, since infancy. When six years of age he had been bitten by a dog, and from that time he had been subject to attacks of *petit mal* during the day and of major epilepsy at night. During the latter he used to bite his tongue and lose consciousness. He looked idiotic when he first appeared, and his face was pale and bloated. His disposition was mischievous, disobedient, and brutal.

He was put under hypnotic treatment, and was hypnotized once a week for several months. The treatment produced a speedy improvement in all the symptoms; the attacks ceased both by day and night, and, *pari passu*, his character altered for the better. His intelligence awakened, and he became able to go about alone, and to occupy himself with employments which were formerly quite beyond him. The treatment being discontinued for a month led to a return of nocturnal attacks, but a renewal of the suggestions again caused these to disappear.

4. Mademoiselle P——, aged twelve, came under treatment exhibiting spasm of the eyelids. Her disposition was extremely perverse and unmanageable. In the month of May she had crises every four or five days, during which she lost consciousness and passed water involuntarily. After the attacks she used to remain completely blind and deaf for a considerable time. The child, from being bright and intelligent, had become dull and apathetic, and had been obliged to leave the school where she had formerly been a promising scholar. The case had been seen by many doctors, who had diagnosed epilepsy, and had prescribed bromides.

A few sittings sufficed to bring about a cessation of the attacks and a return to the previous mental condition. Dr. Bérillon, in view of the very rapid recovery, is inclined to consider this a case of hystero-epilepsy.

CASE 30.—*Intermittent Fever, cured by Suggestion.*

A young man, a hystero-epileptic, came under treatment at the clinique at Amsterdam suffering from quartan ague. He was treated for six weeks by quinine and arsenic, but without benefit, and then begged to be hypnotized.

He was hypnotized during the apyrexia, and at once became somnambulic. But the attack came on as usual, though suggestions were made at four sittings. He was then told to come again for treatment a quarter of an hour before the access of the cold stage, which generally lasted about an hour. He was hypnotized, and suggestions were made for the space of an hour against the occurrence of the symptoms. They were successful, and the usual time for the attack was passed. The patient was left sleeping, but the doctors began to attend to their other patients. Left alone, the patient soon began to shiver, and the algide stage made its appearance with blueness of the nails, shivering, and restlessness. The quieting suggestions were recommenced, and were continued for half an hour with energy and perseverance. Gradually the symptoms disappeared, and the attack was aborted. From that time there was no return of the fever.

(This success encouraged the writers to undertake the treatment of a lady suffering from obstinate remittent fever of South American origin. The patient was only slightly influenced, and the suggestions did not exert any effect on the course of the disease.)

CASE 31.—*Syphilitic Retinitis and Optic Neuritis.*

Emile X——, clerk, contracted syphilis in 1875. He was treated in the ordinary way, and apparently cured. In 1879 he experienced some impairment of sight, which was rectified by the use of convex glasses. In 1881

cutaneous eruptions made their appearance, but his sight continued good for two years longer. Towards the end of 1883 he began to find it difficult to read small print, and to be troubled by sparks and flashes of light before the eyes. From this time his sight rapidly deteriorated, in spite of treatment by mercurials, iodides, strychnia, electricity, etc., at the hands of Professor Fuchs, of Vienna, Professor Huel, of Liége, and other well-known oculists.

In December, 1885, he was unable to see how many fingers were held up at a greater distance than 30 cm. with the left eye, and was unable to count them at any distance with the right eye.

In the left fundus there was a central scotoma, and the right eye had lost the inner half of its field of vision.

The right eye, which afterwards became the better of the two, appeared to be atrophic, its arteries were contracted to half their proper size, and the veins were also diminished in calibre.

Dr. Delbœuf recognised this case as one in which crucial experiments might be made in gauging the action of hypnotic suggestion, and in January, 1887, he began to hypnotize the patient, Professor Nuel and Dr. Leplat assisting him and conducting the examinations and tests.

The treatment lasted from January 17 to July 6, 1888. During this period the patient was hypnotized forty-six times, and each sitting occupied from one to two hours. There was very marked improvement at the end of the treatment, and it is evident that hypnotic suggestion was the curative agent. Emile X—— could count the fingers at a distance of 3 metres with the right eye, and at 1 metre with his left. He was not able to read, but could take notes, see the time on his watch, distinguish colours, and walk without being led. He had lost his strabismus, and could see both eyes when he looked in the glass, showing that his sight can become central. The improvement has been maintained up to the present time, though the treatment has not been resumed.

The suggestions were made by Dr. Delbœuf, and were

always directed towards a definite object. For instance, if the patient could count the fingers at 1 metre before sleep, he was told during sleep to count them at 1·60. On awaking, he would probably be able to count them at 1·30, and this gain would be maintained until the next sitting, when the distance would again be increased.

At other sittings the experiments were confined to attempting to affect the visual field. In one sitting, for instance, its supero-temporal diameter was extended from 75·20° to 90·10°. In three days it had fallen back to 85·20°, but suggestion brought it to 90·5°.

In addition to being almost blind, the patient, when he came under treatment, was affected with great mental depression and haunted by continual thoughts of suicide. He was also an excessive smoker. Two or three suggestions entirely removed this mental condition, and also completely corrected his desire for tobacco.

Case 32.—*Epilepsy*.*

The following case had been under my care as an out-patient since March, 1888. She had been a regular attendant, and although there was considerable improvement under the continuous exhibition of bromides, the case became stationary, and no further progress was noted. Indeed, the mental condition began to excite alarm in the minds of her relatives, as she became morose, irritable, would sit in a corner for hours, and for a long time past had given up all interest in domestic affairs.

October 2, 1890.—E. K——, aged twenty, a tailoress, had epileptic fits since childhood. No other member of the family is the subject of fits; there is no history of insanity or other neurosis. The fits generally occur about the monthly periods, and are often exceedingly severe.

This morning her mother brought her as usual, and I suggested that hypnotism might be of use in improving

* Contributed by Dr. Outterson Wood.

her mental condition. I then hypnotized her to the second degree, and told her mother to bring her again in a day or two.

October 7.—Her mother brought her to-day, stating she had been suffering excruciating pain from neuralgia in the *right* side of her face, so much so that they had had no sleep with her for two nights. I again hypnotized her, suggested freedom from pain, and on awakening the pain had entirely gone. She never had another symptom of neuralgia until February 14, 1891, when she had a slight attack in the *left* side of the face which at once yielded to hypnosis and suggestion.

From this time to May I hypnotized her regularly at intervals of a week, suggesting improvement in her health, that she would become stronger, brighter, more cheerful, and would occupy herself in household duties.

Her mother now states that she has steadily improved in her mental condition since she has been hypnotized; that she soon began to do work about the house, a thing she had not done for years before; that, instead of being a source of care and anxiety on account of her irritability and violence, which led to direct assaults upon those around her, she is now cheerful, singing about the house and taking her share of the work. Her fits are less frequent, decidedly less violent, and she is able to go to dances and enjoy herself.

CASE 33.—*Acute Mania with Exacerbations during the Period. Prolonged Hypnosis. Cure.*

The following case is one of several similar ones reported by Voisin, and illustrates treatment by prolonged hypnosis.

A girl aged twenty was admitted into Dr. Voisin's ward of the Salpêtrière in 1896. She was subject to attacks of violent rage, during which she rolled on the ground, tore up her clothes, and refused to do any work. These attacks were especially violent at the period, when it was necessary to confine her in a strait-waistcoat. During that time she incessantly used outrageous and obscene language.

Voisin hypnotized her at the beginning of a period, and she proved somnambulic. He suggested that she should sleep for six or seven days, during which time she should lie quietly in her bed, and rise from it only to satisfy the requirements of nature and to eat what was given to her.

The suggestions were realized, and the girl remained perfectly quiet. She was awakened when the period ceased, and was much more self-controlled the next two weeks. Before the next following five periods Dr. Voisin again hypnotized her and repeated the same suggestions, and she was then discharged cured.*

* * * * *

I propose here to record a few cases from my own practice which will perhaps prove interesting.

CASE I.—*Insomnia.*†

A. T——, aged thirty-five, electrician, came to me on February 1 complaining of sleeplessness. It seemed to date from a severe accident from the explosion of a torpedo three years before. He is a man of exceptional mental activity, and the want of sleep had induced much nervous depression and dyspepsia. At whatever time he went to bed he awoke at 3 a.m., and was unable to sleep again. He was readily hypnotized, and a slightly lethargic condition was induced. Suggestions were made that he would sleep well that night and would not awake at 3 a.m., but that if he did awake he would be able to sleep again. February 2, he reported that he had awoke the previous night at the usual hour, but had soon dropped off asleep again. The treatment was repeated. February 3, he had been awakened the previous night by a noise in the street about 4 a.m., but had fallen asleep again; on the 5th he reported having had two good nights. One repetition of the treatment completed the course, and since that time he has remained a good sleeper, getting an average of eight

* *Op. cit.*, p. 16.

† This case and several of those following were published in the *Lancet*, August 24, 1889.

hours' sleep every night. His general health has improved to a corresponding extent.

This case presents several points of interest. Though the patient was only affected to a slight degree by hypnotism, suggestion was successful in breaking a morbid habit of three years' growth in less than a week. Mr. T—— tells me he never lies down during the day, and that while lying down in my consulting-room he was completely conscious, but felt comfortable and disinclined to move. He was able to open his eyes, but they felt somewhat heavy, and he experienced reflex warmth in any part where I placed my hand and 'suggested' it.

CASE 2.—*Neurasthenia.*

R. H——, an American, aged forty-three, press agent, consulted me in June, 1889, for pains in the back, depression of spirits, languor, loss of appetite, constipation, muscular weakness, dull pain all over the head, but worse in the forehead and on stooping. He had worked very hard all his life at newspaper editing, and he looked at least ten years older than his age. Physical examination revealed no organic disease, but the heart's action was rapid and feeble, and he had some tenderness over the dorsal region of the spine.

He was easily hypnotized, and fell into the second stage. The treatment consisted in rubbing his spine, loins and abdomen, and suggesting increase of strength, absence of pain, and regular action of the bowels every morning. The patient improved rapidly under treatment, and was able to return to America after twenty operations, quite set up and in good spirits.

This seems to me a typical case of breakdown in an overworked man of nervous temperament. I allowed him to remain in the hypnotic state an hour daily, and no doubt the rest was an important factor in the cure. He was unable to open the eyes, but could raise or depress the arms at will.*

* Two years afterwards (July, 1891) this patient again came under treatment for influenza. He had continued perfectly well, and able to

CASE 3.—*Writer's Cramp.*

Alice N——, clerk, aged twenty-five, came under treatment in March, 1889. She had had much writing to do, and for three years had felt symptoms of loss of power in the right hand and want of control over the pen. She had been treated at a general hospital by galvanism for three months without benefit, and had become so much worse that she had been obliged to leave the desk and engage in other occupations. She was also unable to use the needle for any length of time on account of cramp supervening. After writing two or three lines, she experienced crampy pains in the thumb and forefinger and in the flexor muscles of the forearm. After a few lines, spasmodic jerking of the thumb was observed, and this increased—together with the pains—to such an extent that in less than a minute the patient declared her inability to hold the pen any longer. There was marked tenderness and soreness on pressure over the median and musculo-spiral nerves. She was hypnotized, and fell into the third stage. In that condition the muscles were rubbed, the joints exercised, and suggestions of improvement made.

After a few minutes' rest the patient was directed to again write, and she found the fatigue and cramp had disappeared and did not return until she had written half a page. She came regularly for treatment three times a week for two months, and at the end of that time was able to return to her original post quite cured.

She was a good example of the second or cataleptic stage (Liébeault), which she never passed beyond. She lay apparently fast asleep, was unable to open the eyes, and retained the arm rigid in any position I placed it. But she remained vividly conscious, and was able to repeat the conversation going on around her, and would laugh, protest and struggle when told she was unable to move the arm. This is one of five cases of occupation

---

work ever since the treatment. He made an unusually rapid recovery from the influenza under ordinary treatment aided by hypnotism.

neuroses which I have treated by suggestion. One case was not susceptible to hypnotism, but all the others improved rapidly, and were cured. I should certainly always combine it in these cases with local massage, though I believe at Nancy they use no treatment but verbal suggestion.

CASE 4.—*Tabes Dorsalis.**

H. F——, aged forty-seven, a valet, came under treatment in March. He was pale, anæmic and emaciated, and had an expression and appearance of great depression. His family history was good. He had never drunk to excess or had syphilis, and was married and had a healthy family. In 1870 he was a soldier in the German army, and was wounded severely in the leg, but made a good recovery. In 1884 he had an attack of what he calls blood-poisoning, but what appears to have been typhoid fever, on the Continent, and he has never been really well since. In 1888 he noticed some failure of sight, and at the same time a numbness of parts of the skin of the back and chest became apparent. His bowels became constipated and only moved by the aid of purgatives, which, however, caused so much colicky pain that the action was always accompanied by vomiting and followed by prostration, which kept him confined to bed for the following twenty-four hours. He suffered from frequent sharp 'lightning' pains down the arms, and especially the legs, and from neuralgia in the chest and back. His tongue was dry and coated; he had no appetite, and there was great mental depression. In twelve months he had lost 2 stone in weight, was unable to walk more than half a mile, and always felt tired. The pupils were contracted and almost insensible to light, and there was almost complete atrophy of the right optic nerve, with partial atrophy of the left. The reflexes were absent, but there was nothing ataxic in his

* This case is published in the 'Comptes Rendus' of the first International Congress on Hypnotism.

gait. Extensive patches of local anæsthesia occupied almost the whole of the left chest and back, and also the skin of the upper lip and nose. He was hypnotized, and fell into the third stage.

Suggestions were made as to regular and painless action of the bowels, absence of pain, etc. The next day he had a slight motion (the first natural one for three months) without much pain, and felt better generally. Improvement was steady and constant, and in two weeks he was able to walk two or three miles without fatigue, was free from pain and discomfort, and the bowels were regular.

With the exception of a slight relapse, following a bad chill in June, he has continued fairly well and comfortable. The disease no doubt progresses, but it does so slowly and painlessly. On finding such great success followed suggestions, I was induced to try if they had any influence on his sight, and one morning suggested increased warmth and circulation, followed by improved vision, keeping my fingers over the eyes for three or four minutes. The effect was somewhat surprising, for the following day he was able to read ordinary print at a distance of 6 inches with his left eye, and to distinguish the hands of the clock at 2 feet with his right—a wonderful improvement on his performance the previous day, when he could barely make out large type (D = 4) with the left eye, and could not distinguish the nature of any object with the right. But the improvement was only temporary, and in spite of repeated suggestions his sight had relapsed to nearly its former condition within a week. He told me a somewhat similar result followed some months previously the administration of strong doses of strychnine by hypodermic injection. Still, he invariably saw more clearly and distinctly after being hypnotized than before, and whereas his sight was steadily deteriorating previous to this treatment, it afterwards remained stationary for years.*

* This incident throws some light on cases of 'miraculous' recovery of sight which one reads about as occurring at Salvation Army gatherings, etc. In purely hysterical cases no doubt permanent cure is sometimes brought about by suggestion, aided by expectant attention, when

Probably the explanation of the sudden improvement is that suggestion had powerfully stimulated the healthy nerve elements to abnormal activity, which, however, could not be maintained. I may add that suggestion did little or nothing for the local anæsthesia, but that symptom was greatly modified by a course of suspension under Dr. de Watteville.

This patient was conscious of what went on around him, and by an effort of attention could follow the conversation and repeat its purport, but voices sounded indistinct and far off, and he felt very disinclined for exertion. It is the stage of automatic continuative movement, as shown by a simple experiment. If I gave his arms or hands a few turns and told him to go on with the movement, he was unable to stop it, but continued the action indefinitely. He answered questions addressed to him, not only by me, but by bystanders, and he awoke spontaneously in about fifteen minutes. If told to awake at the end of a certain number of minutes, he used to do so almost to a second.

CASE 5.—*Torticollis, etc.*

W. T——, aged thirty-four, consulted me in March for rheumatism of the muscles of the neck, shoulders, and back. She was a rheumatic subject, and the present illness dated from two weeks previous, when she had been exposed to wet and cold. She had been unable since that time to dress or undress herself, and the least movement of the head or upper extremities caused pain. The muscles were tender to the touch, but there was no swelling or constitutional disturbance. She was advised to try hypnotism, and with some reluctance, as she said she did not believe in it, she consented. In less than a minute she slept profoundly, and while in the sleep the

---

the nervous system is thrown off its balance by enthusiasm and by the impressiveness of the surroundings—is, in fact, in a condition analogous to hypnosis. One knows that many of such cases relapse in a very short time when the effect of excessive nervous stimulation subsides.

affected muscles were well rubbed, and the head turned in different directions. Within five minutes she was awakened and told to move her head and arms freely. This she did without pain, but said there was some stiffness remaining. The stiffness continued until the following morning, when it disappeared and did not return. Faith had nothing to do with this result, for even after the relief was given the patient refused to believe it could be anything but temporary.

This patient appeared entirely unconscious of the conversation going on around her, and of external impressions generally, except such as were rendered apparent to her by my suggestions. She was insensible to pain, as shown by her perfect tranquillity when I moved her head, a movement she had previously been unable to endure. Her eyeballs were turned up, and the conjunctivæ were nearly insensible to touch, but the pupils readily contracted to light. She took no notice of any sound except my voice, and did not appear to hear if anyone else addressed her unless I told her to answer. Her pulse and respiration were slightly slower than in the waking state, and her aspect generally resembled that of profound natural sleep. The knee-jerk was increased by paresis of the inhibitory centre, until I told her to control it, and then it became less than normal.*

She was not susceptible to post-hypnotic suggestions regarding actions or conduct, nor to suggested hallucinations or delusions of the senses.

Case 6.—*Headache following Injury.*

E. H——, post-office clerk, aged thirty-two, came under treatment in July. She had been knocked down by a bicycle three weeks previously, and had fallen with her head against the curbstone. Her back also had been strained, and she had pain in raising the left arm.

She was anæmic, and of neuropathic constitution.

* Dr. Myers tells me he has seen the knee-jerk apparently suppressed by suggestion in Bernheim's *clinique.*

Pressure on the occipital and right parietal region increased the pain, which, however, had never left her since the accident. She had been stunned, but not rendered actually unconscious. She was one of the most susceptible subjects I have ever seen, and within half a minute of being told to look at my fingers and go to sleep, her eyes closed, and she fell into a stage of profound somnambulism (sixth stage). Her head was gently, and the shoulders somewhat more vigorously, rubbed, and suggestions were made tending to the removal of pain and shock. In ten minutes she was awakened by being told to count up to twenty and awake when she got to the end —a good method, as it avoids giving a sudden shock, and leads up to the change of state gradually. She left the house absolutely free from pain, and there has been no relapse. In a profound somnambulist of this type the most advanced phenomena of hypnotism are demonstrable. She is in the same condition, apparently, as case No. 5, but differs from her in being susceptible to post-hypnotic suggestions—negative hallucination, delusions of the senses, automatic actions, etc. It is important, therefore, to safeguard such a subject by telling her she is not to be hypnotized except for medical purposes, by a medical man, at her own request.

Case 7.—*Chronic Diarrhœa.*

General B——, aged seventy-two, came under hypnotic treatment on April 3. He had previously been attended by me for chronic diarrhœa, but without much effect, and the malady was generally considered quite incurable. It dated from the time of the Crimean War, and since then he had never passed less than four motions a day, and these were always thin and watery. Any excitement or emotion aggravated the condition, and the day previous to my visit he had been moved twelve times. He is a man of exceedingly nervous type, but enjoys fairly good general health for his age. Hypnotism produced very much the same effect on him as on the patient in Case 1

—a slight lethargy. In this state his abdomen was gently rubbed, and the suggestion made that he should in future have but two motions a day, and that they should be properly formed. On April 4 the patient reported three motions during the last twenty-four hours. He was again hypnotized, and the same suggestions were repeated. On the morning of April 5 he passed the first formed motion he had had for over twenty years, and from that time his bowels continued to act regularly twice a day and the stools were well formed and natural.

CASE 8.—*Paroxysmal Sneezing.*

F. H——, thirty-eight, lady's-maid, suffered during the summer of 1888 from hay-fever, and the fits of sneezing continued into the autumn, so that when I saw her on October 4 she told me that every morning on awaking she was seized with a paroxysm, which lasted about an hour, during which time she sneezed about forty times, and discharged copiously from the eyes. In addition to this, for a few days she had suffered from pain after eating, flatulence, and constipation. She was hypnotized, and at once fell into a profound sleep (Liébeault's sixth stage). Her nose was rubbed, and the suggestion made that she should sneeze no more. The stomach was also rubbed, and the suggestion made for the regulation of the digestive functions. There was no need to repeat the operation, for the paroxysmal sneezing ceased forthwith, and the digestion became easy and painless. There has been no relapse.

CASE 9.—*Chronic Constipation.*

Mr. H——, aged thirty-nine, solicitor, of lymphatic temperament, consulted me in May, 1889, for constipation. He had led a very sedentary life, and was in the habit of taking a good deal of opening medicine. His appetite was capricious and his tongue furred. He was hypnotized, and rapidly fell into the third stage. The abdomen was well rubbed, and a regular motion suggested daily after breakfast. The treatment was almost im-

mediately beneficial, and six operations sufficed to establish a regular after-breakfast habit of relief.

CASE 10.—*Supra-orbital Neuralgia.*

E. H——, a stockbroker's clerk, aged twenty-one, came to me in July suffering from neuralgia of ten days' duration. The pain came on in paroxysms which were worse at night, and it was chiefly felt over the right eye, where there was extreme tenderness. But the pain radiated over the anterior part of the head, and sometimes affected the eyes. He was out of health generally and very depressed. He fell into the second degree of hypnosis, and the treatment consisted in rubbing and suggestions. He was allowed to remain in a drowsy state for half an hour, and was then aroused. He said he felt much better, and he passed a fairly good night. Three operations effected a complete cure. It was his first attack of the kind.

CASE 11.—*Spinal Irritation.*

Mrs. F——, aged thirty-seven, came under treatment in April, 1889. She had suffered since the birth of her first child, ten years before, from pain and discomfort in the spine, referred especially to the lumbar region. She was unable to walk without great fatigue, and standing was a misery to her. She was anæmic, of constipated habit, and with general depression of vitality. Manipulation down the spine caused pain, and there was frequently numbness of the extremities with twitchings. Her mental condition was one of depression and great nervous irritability. She was susceptible to the third degree, and began to improve under suggestion almost immediately. The case, being of very chronic nature, required a longer attendance than usual, and she occasionally came up for a repetition of the treatment. She greatly improved in appearance, the irritability of temper subsided, and she was able to walk two or three miles, and stand about in picture-galleries and exhibitions, as well as most ladies, without undue fatigue.

CASE 12.—*Functional Heart Trouble.*

H. L——, twenty-three, consulted me in November, 1888, complaining of palpitation on exertion and on lying down at night, shortness of breath, giddiness and frequent attacks of fainting coming on without any warning. Examination of the heart revealed no organic disease, and all the organs seemed healthy. She had suffered a good deal of anxiety of late, and this was apparently the cause of her illness. She was treated on general principles with iron, nux vomica, digitalis, etc., but she made little or no progress, so in January, 1889, I suggested hypnotism and soon induced the third degree. She began to improve almost at once under suggestions, directed to the over-action of the heart, and after ten operations, spread over a period of three weeks, was relieved of all her symptoms.

CASE 13.—*Symptoms dependent on Mitral Disease.*

Miss H——, aged thirty-two has been under my treatment on and off for several years, and after a long spell of literary work and late hours she consulted me in March, 1889, complaining of palpitation, frontal headache, loss of appetite, nausea, constipation, debility, swelled feet and legs, and especially of attacks of faintness coming on without apparent cause. She has mitral regurgitation consequent on rheumatic fever ten years ago, and her pulse was very weak and rapid (104). She was hypnotized and fell into profound somnambulism. Reduction in the rapidity of the heart's action with increase of force was suggested, and the pulse after a few minutes became reduced to 87, and of firmer character. Suggestions were made coresponding to all her symptoms, and she was allowed to rest for nearly an hour. On awaking she at once said she felt much better. The nausea which had troubled her incessantly for several months had disappeared, and she felt no discomfort from her heart. On going home she slept well that night, and the improvement was maintained the next day. The following day

she came to me complaining of a fresh attack of palpitation, and she was again hypnotized, with the same result as before. The operation was repeated three times, with an interval between each visit of three days, and she was then quite free from pain and discomfort. During the hypnotic treatment I purposely refrained from giving medicine, but afterwards I prescribed strophanthus for the swelling of the feet, which had not improved much under suggestion. This medicine almost completely removed that symptom in a couple of weeks. She had no more attacks of syncope after the first operation.

CASE 14.—*Nocturnal Enuresis.*

Thomas L——, aged thirteen, was brought to me in June, 1889, for this trouble. His parents had never succeeded in breaking him of the habit, though they had tried many different modes of treatment. He was fairly well-nourished, intelligent, and of nervous temperament, He had no organic lesion of any kind, and the malady evidently depended on functional weakness and bad habit. He was hypnotized daily for six days and then once a week for six weeks, and he always fell into a profound sleep. He wetted the bed once the first and once the third week, while previously he had rarely gone more than two consecutive nights without doing so. After that there was no return of the trouble, but he wakes up every night about twelve and empties his bladder quite automatically. The boy's future was in danger of being compromised, as his parents were unable to get him into any public school. He went to a large school afterwards and did well. I told him he was to always wake at twelve and leave the bed, and the suggestion acted excellently well.

CASE 15.—*Gouty Sciatica.*

Mr. S. R——, a gentleman aged eighty-one, had been for many years a patient of mine, and was subject to attacks of gout, which showed itself in various ways. On this occasion (July) it took the form of sciatica of the right

side. There was extreme tenderness along the whole course of the sciatic nerve, and the pain was very severe. The treatment I had previously adopted — colchicum internally and poppy-head fomentations externally—was practised, but he continued to suffer much and to be unable to sleep, so on the third day I proposed hypnotism, to which he gave a ready assent. In a few minutes—using verbal suggestion and fixation of the eyes—he went off into a light doze, and in that condition his thigh was well rubbed and absence of pain suggested. The old gentleman remained in a somnolent state for about ten minutes, and awoke feeling somewhat relieved. He slept well that night, and the operation was repeated daily for three days, with the result that he was able to leave his bed within a week, whereas previously he had always been confined to it for three weeks by similar attacks. He was an extremely nervous and sensitive subject.

CASE 16.—*Chronic Rheumatism with Wasting of Muscles.*

Mary T——, aged thirty-four, dressmaker, was sent to me in July, 1889, suffering from very intractable rheumatism of the right shoulder and elbow. It had lasted for three years and caused great pain on moving the arm. The illness had come on gradually and had resisted all treatment. The patient was somewhat anæmic, complained of constipation, and was kept awake at night by the pain. The deltoid and muscles of the arm were a good deal wasted, but gave a normal reaction to electricity.

She at once fell into the third stage of hypnosis, and in this state her shoulder and elbow were rubbed and warmth and absence of pain suggested. She was able on being aroused to move her arm almost to a right angle with her body without pain, which she had not previously been able to accomplish. She remained under treatment for three weeks, and at the end of that time returned to the country absolutely free of pain and able to move the arm freely in any direction.

CASE 17.—*Nervous Dyspepsia.*

Miss L——, aged thirty-two, consulted me in February, 1889. She had suffered more or less all her life from indigestion. She was very thin, and her complexion was yellow and spotted with papules of acne. She complained of constant pain over the epigastrium, which was tender on pressure, increased by food, and accompanied with 'sinking,' heartburn, and palpitation. Her circulation was deficient, and she had always cold hands and feet; there was frequent headache and neuralgia, generally in the frontal region. She slept badly at night, and was troubled with uncomfortable dreams. She felt languid and despondent, and had no aptitude for setting to any occupation. Her condition was becoming worse, and she had been under all sorts of medical treatment for her digestion since childhood. Her teeth were sufficiently good for mastication, the bowels were constipated, and the tongue was moist but furred. There were no symptoms pointing to disease of any organ, and it was evident the malady was purely functional.

She was hypnotized, and the second degree of hypnosis was induced. In this condition the stomach and abdomen were rubbed and warmth suggested. Comfortable sleep and improved appetite were promised, together with regular action of the bowels, and general increase of strength and energy. The patient was on very rigorous diet, and this was somewhat modified and enlarged. Improvement in her condition became visible after two or three days, and the treatment was repeated daily for ten days, and then at longer intervals for a month. At the end of that time she was better than she had ever been previously. She slept well, ate with fair appetite, and enjoyed life. The improvement has been maintained, and the morbid condition seems permanently cured.

CASE 18.—*Amenorrhœa.*

E. S——, aged twenty-four, consulted me for various symptoms dependent on amenorrhœa in May, 1889. She

was pale, somewhat anæmic, ate and slept fairly well, but suffered from nearly constant frontal headache. She had seen nothing for five months, and thought the cause of this was a chill incurred at the time of the last period. She had taken iron and quinine and used hot baths without effect. She was hypnotized, and at once fell into a profound state of somnambulism. I rubbed the abdomen, and suggested that the period should come on the following week, without pain, and should last three days. These suggestions were repeated daily, with the addition that the day of the week (Friday) was suggested after the second visit. Early on the following Saturday morning the function was re-established, and lasted three days.

CASE 19.—*Functional Dysmenorrhœa.*

A. T——, aged twenty-one, clerk, came under treatment on October 10, 1888. She suffered much from painful menstruation, and has done so since the function became established four years previously. The period was always delayed three or four days, and was scanty and light-coloured. It lasted about three days, and was attended with excessive backache, languor, and frontal headache. She suffered also from gastralgia, constipation, and flatulence. After treating her for some time on general principles, she was hypnotized on March 15, immediately after a period, and at once fell into a profound sleep (Liébeault's sixth stage). Suggestions directed to the painless performance of the digestive and menstrual functions were made, and were repeated two or three times a week for four weeks. The following period appeared on the twenty-ninth day, and was attended by but little pain or inconvenience. She was told to return in three weeks, and suggestions were then made regarding the next period. This came on twenty-seven days after the last, and continued for four days. It was more abundant and healthy, and perfectly free from pain. Since that time she has continued regular, and there has been no dysmenorrhœa. The digestion soon became

painless and natural, and the general health shows great improvement.

CASE 20.—*Post-Parturition Troubles.*

F. Y——, aged forty-three, was confined of her fifth child in January, 1889. She was anæmic, and had suffered during her pregnancy from severe colicky pains, constipation, hæmorrhoids and occipital headache. Delivery was tedious, and there was much hæmorrhage from the relaxed and insufficiently contracted uterus; and the placenta had to be removed, as it remained adherent. The patient complained greatly of headache and restlessness after the confinement; the uterus contracted but slowly, and there was also much pain, in spite of hot douches and ergot. She was hypnotized by being told simply to look at my outstretched fingers and go to sleep. In a few minutes the eyelids began to twitch, and on closing the eyes she sank into a comfortable sleep, which lasted for four hours. She awoke much refreshed, and without headache. The operation was repeated daily for four days, and she made an unusually good recovery.

CASE 21.—*Dipsomania.*

L. G——, a gentleman of position, who was intensely anxious to be cured, was under my care during the month of January, 1889. His case was a bad one, and for three years had been getting worse. Uncontrollable fits of craving for spirits recurred every two or three weeks, and indulgence for three or four days was followed by intense nervous depression. He was hypnotized twice daily, and, like most of these patients, he proved a very susceptible subject. Suggestions were always made that he should look upon spirits and intoxicating liquors generally with dislike, and that he should have no craving or wish for them. Under this treatment his appetite soon became very good; he slept well at night, and recovered his spirits. In four weeks he was able to return to his family, and he

writes at intervals, telling me that, in spite of some exceptional temptation, he has no inclination to taste alcohol or break his promise to me.

CASE 22.—*Moral Breakdown.*

T. L——, aged twenty-one, engineer, was sent to me for treatment by suggestion by a medical friend, as all ordinary treatment, medical and surgical, had failed. Since early adolescence he had practised private vices, which had reduced him to a deplorable state of mental and physical weakness. He was easily hypnotized, and fell into the fourth stage of hypnosis. Suggestions were made directed to the reduction of morbid functional activity, and to increase of power of self-control. The patient, who thought himself on the verge of insanity, was a willing patient, and is now after five months a completely altered man. He comes to me at gradually lengthening intervals, and in that way any danger of a relapse is obviated until the influence of the habit is absolutely eradicated.

I was enabled to form a good estimate of the value of hypnotic treatment, as I was asked to try it on two brothers who were both terribly addicted to masturbation. The elder one, aged eighteen, proved unhypnotizable after repeated efforts, and the younger, aged fourteen, became somnambulic almost at once.

In the former case the patient has gone from bad to worse, and is now in a lunatic asylum with delusions of persecution. The latter is now four-and-twenty, and fills a responsible post in South Africa. He has had no relapse from the first day he was treated.

Sexual Perversion.—If hypnotism had done nothing more for medical science than bring such melancholy cases as the above within the scope of curative treatment, it would have conferred a lasting benefit on humanity. In even worse cases of perverted sexual instinct it is frequently successful, and Dr. Von Schrenk-Notzing, of Munich,

read before the International Congress notes on a case of this kind, treated by him with the happiest results. Modern medicine teaches us that these perverted instincts depend upon a hereditary or acquired morbid condition of the brain and spinal cord, and constitute, in fact, a psychical disease. Hypnotic suggestion seems to act by checking excessive functional irritability, and by developing and bringing into play the inhibitory action of the higher brain centres, which have either not developed or have undergone impairment.

In consequence of the translation into English of Krafft-Ebing's classical work, 'Psychopathia Sexualis,' and his reference to hypnotism as the best, if not the only, method of bringing about the cure of these cases, I have been consulted in quite a number of them; at least twenty in ten years. In one of them hypnotism was completely successful, and the patient is now happily married. In several of the others considerable improvement was effected, but, unfortunately, most of the patients were but indifferent subjects.

In treating cases of sexual inversion the hypnosis should be very profound, for one has to alter by suggestion a set of very deeply ingrained instincts and emotions.

Wetterstrand (*op. cit.*, p. 50) reports having cured a case. The patient was a man of thirty-two, and he was cured in seventeen sittings. He became somnambulic at the first sitting.*

It is absolutely necessary to gain the confidence of the patients in these cases, and they must be carefully watched, as they are notoriously given to deception. But their confidence can be gained by judicious management, and then one is saved from the danger of allowing 'the wish to be father to the thought.'

The two following cases possess considerable interest,

* Doctors, lawyers and teachers who wish to investigate this rather unsavoury but very important subject will find it fully treated of in Krafft-Ebing's book, and in the recent work by Dr. Havelock Ellis, 'Studies in the Psychology of Sex.'

owing to the intellectual attainments of the patients, for they confirm the assertion that hypnotizability may be rather a sign of intellect than the reverse :

CASE 23.—*Cure of the Tobacco Habit.*

Dr. X—— is a University professor of eminence, and he came to me in June, 1890, to try what hypnotic suggestion would do to cure him of smoking. He had been an inveterate smoker for twenty years, and had never succeeded in breaking himself of the habit, though he had made frequent attempts. He was highly nervous, and complained of sleeplessness, palpitation, mental irritability, and dyspepsia—all probably due to the very large quantity of tobacco he was consuming in the form of cigarettes. He was easily hypnotized, and fell into the second stage. I suggested that he would cease to care for tobacco, and that he would find himself able to break off the habit without difficulty. The operation was repeated daily for three days, and the patient then discontinued treatment. On making inquiries, I have received a letter from him from which the following is an extract :

'The suggestion was immediate in its effect, so that I felt no craving for the weed, although I had been a habitual smoker for nearly twenty years. Of course I felt very uncomfortable, and my life was very much upset at first by my sudden change in habit ; nor did I experience at once all the benefits that I expected from abstinence ; so that had I not been under influence I should certainly have relapsed (to my everlasting regret), as I had done whenever I relinquished the habit before being hypnotized. I begin to think that I must now be tobacco-proof, and have not smoked once since I saw you, and am in very much better health.'

This was an admirable case to treat. The patient knew that tobacco was poison to him, and was full of good resolves about giving it up. The will only needed a strong reinforcement from outside, and this was supplied by suggestion in the hypnotic state.

CASE 24.—*Neurasthenia.*

Mr. A——, aged twenty-four, has taken a distinguished degree, and is a man of markedly neurotic and intellectual type. He came to me in 1890 suffering from nervousness, sleeplessness, restlessness, and other symptoms of overwork. He was hypnotized at once by fixation of the eyes for about a minute, followed by suggestions, and on his first visit fell into the second stage. He was unable to see me again for three weeks, but he told me that the effect of the one operation was very marked, and that for three days he felt a new man. Then the effect gradually wore off, and on the occasion of his second visit he was in much the same state as when I saw him first. He was more susceptible the second time, and in the course of the treatment he several times passed into the profounder states, with amnesia on waking. I saw him now every alternate day for two weeks, and then once a week for a month. At the end of this course he reported himself as better than he had ever felt before in his life, and able to read the stiffest books for hours together without fatigue. He sleeps well and wakes refreshed and ready to get up, and is able to play tennis, row, etc., without being overtired.

CASE 25.—*Chronic Alcoholism.*

Mr. X——, aged thirty-four, came under treatment in January, 1891. He is a strong, thickset, muscular, and very plethoric man of highly nervous temperament. He had been a heavy drinker for about ten years, but through domestic and business worries had become much worse, and was in imminent danger of losing his employment and means of livelihood. He had had several attacks of an apoplectiform character, and drinking made him dull, heavy, and lethargic. His general health had suffered, but there was no organic disease. He proved one of the best subjects for hypnotism that I have yet found, for he at once fell into a state of profound trance. The operation was repeated daily for three weeks, and he was then

sent to the seaside for a fortnight preliminary to returning to his business. He went on well for ten days, but then received news from home of a distressing character. Worry of any kind had always driven him to liquor, and in spite of the recentness of the suggestions he again sought the usual solace. For two days he drank large quantities of beer—the worst form of alcohol for him—and he was then brought up to see me. I found him in a very restless, excitable state, with quick, bounding pulse and throbbing carotids. His face was of a dusky hue, and he complained of dull heavy pain in the head. On attempting to hypnotize him, I found that instead of falling into a sound quiet sleep he passed into a state resembling coma—from which it was difficult to arouse him. The man was evidently on the verge of apoplexy, and to relieve the congestion I at once applied three leeches behind the ears. They bit very freely, and the effect was very striking. In half an hour danger seemed past, and the next day he was almost himself. It looked as if ordinary suggestion alone had failed in this case, and that stronger treatment than usual was required. I therefore began to suggest, not only disinclination for alcohol, but loathing for it. In the presence of my friend Dr. Arthur, I told him that liquor would act as an immediate emetic if he ventured to take it; and to put the efficacy of the suggestion to the proof, I made him drink half a glass of beer a few minutes after he was awakened. He was quite unconscious of the nature of the suggestions I had made, but I found considerable difficulty in getting him to drink the beer, as he said his stomach seemed to turn against it. However, he drank it, and no sooner was it down than he turned to me and asked where he could go, as he felt extremely sick; in a few moments he brought up all the beer he had swallowed. I then again hypnotized him and told him that he now saw the effect of alcohol upon him, and that similar indulgence would always and at once lead to the same result.

Mr. X—— remained under my observation until the

end of March, when he returned to his home. His regular attendant continued the treatment for a few months very successfully, and hypnotized him once a fortnight. Small business worries no longer fretted him as they used to, and the ever-present domestic annoyances were also borne with equanimity. Though such a susceptible subject, I proved to demonstration that, so far from being rendered more liable to be hypnotized by the repeated operations he had undergone at my hands, he was, on the contrary, less subject to hypnotic influence than an ordinary person. For instance, I requested a medical friend of some experience to try to hypnotize him. Not only did the attempt fail, but the touch and voice of the experimenter assumed a stimulating and irritating character to the feeling of the patient, and rendered sleep, and even rest, out of the question. This was in response to hypnotic suggestions I had previously made, that he was not to allow anyone to hypnotize him but myself, and Dr. S—— (his family medical attendant), except at his written request. There was no particular personal element in this or similar cases which have come under my notice, though, of course, it is desirable that in psychical treatment there should be mutual confidence and esteem between patient and doctor. Association of ideas explains the causation of sickness on taking alcohol, just as it explains why raspberry jam will sometimes produce nausea in adults who, as children, have frequently been given powders in it. The train of ideas once started continues, though circumstances may have completely changed, and the person may never be able to taste that particular preserve, or even to think of it, without experiencing nausea. In the face of such an explanation it seems to me quite wide of the mark to contend, as some do, that the effect of suggestion in these cases is purely personal, and that when the patient goes away the force of suggestion will become weaker, until it ceases any longer to operate as a deterrent. Such has not been my experience, and Dr. Liébeault tells me that

he has records of cases of chronic drunkenness which he treated, and cured, over twenty years ago, which have remained cured.

Total abstinence is not much practised in France, and Liébeault generally allows his alcoholic patients to drink light wine with their meals. A gentleman consulted me as to the benefit he was likely to derive from hypnotism in December, 1888; and as I found him a good subject—susceptible to the third degree—and he was going to France, I advised him to consult Dr. Liébeault. He was hypnotized at Nancy twenty times, told never to drink except with his meals, and then only light wine or beer. His wife was also instructed to hypnotize him and make the necessary suggestions once a week. I frequently see this patient and his friends, and though twelve years and a half have elapsed, he continues a moderate drinker; *i.e.*, he drinks a glass of beer or claret at lunch and dinner. He was a notorious drunkard, and for two years prior to the treatment had hardly ever been sober except under compulsion. Though this line of treatment has been so successful in that case, I do not think it is one to follow—at any rate, with Englishmen—and I consider that total abstinence is the only safe course for people who have given way to drink, whatever plan of treatment is employed. The deprivation of alcohol is no infliction to the hypnotic patient, and there is, therefore, no object in not enforcing it.

Case 26.—*Nervous Prostration.*

Mrs. E——, aged forty-one, came under treatment in January, 1890. She had led an extremely unhappy life for years, on account of the misconduct of her husband, who was a drunkard and a rake. The source of her trouble had been some months removed by his death, and there was no actual cause to keep up her state of ill-health. But the impressions left by years of worry were not removed by simple cessation of the irritation, and Mrs. E—— continued to suffer from sleeplessness, periodic headaches,

constipation, loss of appetite, and intense mental depression. She was hypnotized with great difficulty, and only after six attempts had failed. She never lost consciousness, but fell into Liébeault's third stage. The suggestions I made were directed to quieting the nervous apprehensions which assailed her, improving her appetite, and producing natural sleep at night. The suggestions acted perfectly, and the patient began at once to recover her strength and spirits. The mental depression gave place to a feeling of repose and relief, the headaches disappeared, and she became thoroughly well and strong in the course of two months. The improvement has been continued, and the nightmare of years has been thoroughly dissipated by suggestion. The improvement of mental health has been accompanied by at least equal improvement in her physical condition; she has gained weight, and lost the careworn expression which she formerly wore. Altogether she looks at least ten years younger than she did a year ago, and there has been no relapse.

CASE 27.—*Extreme Anæmia treated by Hypnotic Suggestion.*

E. A——, aged eighteen, shop assistant, has been under my observation for several years, during which time I have occasionally treated her for various slight complaints. Her father is a drunkard, and her mother is anæmic and neurotic. The girl never had any severe illness, and was always remarkably bright and lively until the beginning of 1890. Then she began to droop, complained of feeling constantly tired; lost her fine healthy colour, and became sallow and pale; the period, which had been regular for three years, became irregular and scanty, and the bowels were constipated; she became short of breath on exertion, and was unable to lie down in consequence of palpitation. She developed a hæmic murmur at the base, and a souffle under the clavicles; she ceased to have any appetite, and wished to live on a little tea and bread-and-

butter. The case was thus a typical one of anæmia, and as such I treated it—first by a course of Blaud's pills alone, and, when that proved ineffectual, by rest and a month at the seaside. She returned, however, in April from the sea, little, if any, better for the change. The amenorrhœa had become established, and there had been no show for over three months. Under these circumstances, I felt justified in advising hypnotism, and as the patient and her mother agreed, I hypnotized her on May 1. She proved susceptible to the third degree, and I repeated the process three times a week for a month. The result was very striking, for the girl immediately began to improve. First she commenced to eat her food better, then her bowels became regular, next she lost the buzzing in the ears, and was enabled to lie down at night. Her pulse became slower and stronger, and the hæmic murmurs became less audible; and finally, in obedience to repeated suggestions, there was a slight catamenial show in the third week of May. From that time improvement was rapid, and the symptoms and signs of anæmia steadily disappeared. The patient resumed work in June, and has since continued rosy and well. This is one of a considerable number of cases of anæmia which I have treated by hypnotism, generally only after other measures have failed. One has only to try it in these cases to endorse Liébeault's contention, that hypnotic suggestion comes near being specific in the treatment of simple anæmia. Such patients are nearly always hypnotizable, and are generally very suggestible. I cannot say that I have found improvement or cure so rapid as Dr. Liébeault records in several instances, wherein one or two operations sufficed to bring about a return to health; but I have generally seen improvement set in at once, and continue progressively. Anæmia so often proceeds from some disturbance in nutrition connected with innervation, that one can understand how it may sometimes be reached by mental treatment. In these cases hypnotism acts, I imagine, by placing the system in the best possible state

for natural recuperative processes to operate; it certainly speedily improves the assimilative functions and increases the remedial action of iron.

Case 28.—*Kleptomania.*

The name kleptomania excites a smile in many laymen, and they look upon it as a convenient cloak for the larcenies of the well-to-do. A learned judge is reputed to have replied to a counsel who raised this plea that he was there to cure that disease.

But medical men, especially those who have to deal with neurotic and mentally unstable patients, know that the condition constitutes a real entity, and reference to Hack Tuke's 'Dictionary of Psychological Medicine' shows that there is a considerable literature on the subject. Drs. Auguste Voisin and Edgar Bérillon, of Paris, have reported cases which they have successfully treated by hypnotic suggestion, and the following case affords additional evidence in support of this method of treatment:

A. Y——, aged sixteen, is a well-grown and intelligent youth. There is no history of epilepsy or insanity in the family. The patient lived at home until three years ago, when he was sent to a large public school. He was reserved with the other boys, and did not join in their sports with any ardour; but he worked well, had a good place in the school, and was well thought of by the masters and boys. For a year he got on very well, and then his character gradually underwent a change. He became morose and irritable, and when remonstrated with for his failure to learn his lessons, he replied that it was useless to try when he forgot at once what he learned.

At the same time articles of jewellery and books began to be missed, and when their disappearance was traced to him, and his boxes were searched, the lost property was found in them. He denied all knowledge of it, and became intensely excited when accused of theft. He was told that he must be flogged or expelled, and his relations were sent for. They very wisely, seeing his

condition, decided that he should leave the school, and he returned to his home. He was now very different to what he had been formerly. He was then bright, frank, and affectionate; now he was sullen, irritable, and untruthful. A new school was found for him, which he attended as a day-scholar, but he had to be removed from it in six weeks, as he not only took things belonging to other boys, but also stole books from shops and bookstalls. At the same time he began to scream and gesticulate in his sleep at night, and his outbursts of passion became uncontrollable. He was taken to a well-known neurologist, who pronounced his case one of moral insanity, advised his removal from home, and his being placed under rigorous discipline. He significantly added that he had known a similar case cured by three months' hard labour! The boy was shortly afterwards brought to me, on March 30, 1894, and I thought it a suitable case for trying hypnotism.

He was hypnotized in the usual way, and at once proved a good subject, though on the first occasion he was not somnambulistic. Suggestions were made that he should sleep quietly at night, that the nervous irritability should pass away, that his memory should improve, and that generally he should return to a normal condition. As a mental exercise and test of memory, he was told on his third visit, while in a state of trance, that he was to learn an ode of Horace that evening and write it out from memory the following morning. He carried out this suggestion then, and on a subsequent occasion apparently of his own initiation, for he retained no recollection of my suggestion having prompted it.

He was kept under observation and hypnotized daily for a week, and was then allowed to go out alone, and was hypnotized twice a week for three months.

I did not see or hypnotize him from July 3 to October 30, but on the latter date I found him well and strong physically, and his family assure me that his former sweetness of disposition is entirely restored. His memory

is good, and he no longer talks or gesticulates in his sleep.

There are several points of interest in the case: the alteration of disposition and character, the loss of memory, and the night terrors pointed to an irritative disturbance of the highest cortical centres. His untruthfulness and denial of thefts when confronted with the evidence of them was at least partially dependent on real amnesia, and reminds one of the similar condition often observed after epileptic seizures. Though he was kept under treatment for four months, this length of time did not seem absolutely necessary, for there was an almost immediate removal of the nervous symptoms, and after the first two weeks further hypnotizing was only done as a precautionary measure.

The case was evidently one of degeneration occurring at the age of puberty; and the physiological rest of hypnosis, combined with the stimulating of the appropriate centres by suggestion, brought about a *restitutio ad integrum*, and imparted the needful bias towards healthy action, which tided him over the critical period of adolescence. It is particularly satisfactory to be able to cure a case of this kind speedily and pleasantly, as the method which must be adopted in default of hypnotism is an arduous and not always successful course of disciplinary training, extending perhaps over years.

This is only one of several cases of moral insanity which I have seen successfully treated by hypnotic suggestion, and I earnestly recommend trial of the treatment in these most harassing cases.

I should add that the boy had always stammered, but that this defect became notably worse during the period of mental trouble. Suggestion has had some, but not a very great, effect on this condition. A notable symptom of disturbance of circulation was the frequent flushing of the face and neck. As his nervous system became more stable, this became less frequent, and has now altogether ceased.*

* Reprinted from the *Provincial Medical Journal*, December, 1894.

CASE 29.—*Mischievous Morbid Impulse in a Child.*

The following notes present, I think, many points of interest, and illustrate the value of hypnotism in a class of cases not amenable to ordinary treatment:

M. A——, aged thirteen, was brought to me for treatment in December, 1895.

She was the illegitimate child of a prostitute by a German Jew. Both parents, as far as can be gathered, were drunken and dissolute; and the child was adopted when a few days old by a respectable artisan and his wife, who have brought her up as their own.

The child was small for her age, fair and fragile in appearance, pretty and graceful, and looked very superior to the rank of life in which she was placed; she was of highly nervous temperament, but healthy, and had never suffered from any severe illness.

She was intelligent, and stood well in the Board School she attended. She was very fond of music, and played creditably on the violin.

She was brought to me to be hypnotized for a habit of mischief, which showed itself by cutting up clothing and furniture whenever she had an opportunity. Her own clothes, especially when new, were the chief objects for destruction; and I was shown frocks, hats, and boots which had been destroyed in that way. Everything had been tried in the way of cure, from severe punishment to affectionate persuasion, but no effect had been produced, and the habit had persisted for over seven years. She always denied the acts when accused of them, but afterwards used to confess to them and promise amendment with much weeping. She also habitually bit her nails, a habit which Dr. Edgar Bérillon of Paris has shown to be a very important sign of degeneracy, and she often talked in her sleep. In other respects she was a normal and affectionate child.

Her extreme nervousness made her difficult to hypnotize but on the third visit she fell into a somnambulic state. Suggestions were then and subsequently made,

that she would have no desire to do mischief, and that she would be cured. At the same time, suggestions were made that she would sleep quietly at night, and would no longer bite her nails. All the suggestions acted perfectly. The nail-biting and talking in her sleep ceased at once, and there was only one relapse into mischief, when she cut up a new bonnet belonging to her foster-mother in February, 1896. In June, 1896, she had rather a severe attack of scarlet fever, from which she made a good recovery. Menstruation appeared for the first time in November, 1896, and continues normal. There has been no return of the morbid impulses, and the girl is developing rapidly.*

If the child is intelligent I find hypnosis is easily induced, and that the susceptibility to curative suggestion is very marked. On the other hand, when there is deficient intelligence, hypnosis is almost impossible of attainment; and suggestion, according to my experience, can achieve but little.

Case 30.—*Agoraphobia.*

Mary B—— came to me for treatment in October, 1898. Her age is twenty-six, and she is a Board school mistress. She is a strong, healthy-looking woman and a great bicyclist.

Two years ago she began to notice feelings of discomfort when in crowded rooms, and especially in church. These feelings became gradually intensified, until she was unable to go into shops or any place where there were many people. She was an extremely good subject—sixth degree—and at once responded to suggestion. She returned home in two weeks able to go about like other people, and wrote to me after a year saying there had been no relapse.

Case 31.—*Morbid Self-reproach.*

Thomas N—— was sent to me by a Derbyshire clergyman in 1896. He was a man of forty, a mill operator by

* Reprinted from the *Edinburgh Medical Journal*, June, 1897.

trade. He was a steady, religious man, very affectionate and emotional, but apparently healthy.

About a year before he had taken his son, a boy of twelve, to spend the night with friends, and the boy had been put into damp sheets and got rheumatic fever in consequence.

He recovered after a severe illness, but his father had an anxious time, as he accused himself of being the cause of the illness. Though the boy got well, the father did not recover his spirits, but rather grew worse. He continually brooded over the matter, lost his sleep, became restless, was unable to work, and, in fact, became practically insane.

He proved a good hypnotic subject and became somnambulic at once. I hypnotized him about six times in ten days, and he returned home cured. I have since heard that there has been no relapse, though the boy was taken ill again last year and died. The suggestions were framed to combat the morbid idea, and though the local doctor and clergyman had used the same arguments many times without success, hypnotism served to drive them home.

At the Berlin International Medical Congress Dr. Bérillon was twitted with having only published his successful cases, and he was able to retort that if that was an offence he sinned in good company. The practitioner undoubtedly learns much from his own failures, but I cannot think that they convey much to others. In hypnotism, as in all other treatments, we meet sometimes with failure and disappointment where success seemed assured. Such a case is the following: A lady, aged thirty-eight, consulted me in November, 1890, for partial hemiplegia of apparently functional origin. Though it had lasted for six years, and all kinds of treatment had been tried in vain, I felt justified in hoping for a good result from hypnotism, especially as the lady was very susceptible and speedily became somnambulic. Sugges-

tions were made with great caution, and she was told that she would become stronger and better daily, and on the seventh day would be able to get out of bed and walk without a stick. Though the suggestion was repeated daily and the circumstances seemed most favourable, nothing critical happened on the expected day, and the patient still remains partially hemiplegic. Her general health has, however, improved; she has lost her headaches and feels 'more alive.' Her intelligence, which was in the same condition somewhat as her limbs, has greatly benefited, and she has lost a habit she had of letting things fall that she tried to hold.

Probably in this case the disorder has lasted so long that it has become a part of the patient's individuality, and therefore cannot be cured unless something occurs to completely change that; or possibly the case may turn out to be one of those referred to by Dr. Buzzard, when the earlier stages of disseminated spinal sclerosis are masked by hysterical symptoms.*

Though she frequently becomes somnambulic, she does not completely lose touch with the external world, and though anæsthetic and irresponsive to any voice but that of the operator, she will be seen to smile if something very amusing is said in her presence. She does not, therefore, fall into the profound state attained by Dr. Dumontpallier's patient, in which suggestion is all-powerful, and there is always a degree of unconscious resistance which prevents the suggestions being accepted by the mind and transformed automatically into actions.

Another disappointing case is that of a boy aged ten, who was brought to me to be treated for nocturnal enuresis. He was a natural somnambulist, but hypnotism only induced Liébeault's fourth state. Suggestions were made that he should sleep lightly at night and that he should leave the bed. The suggestion was realized the first night, but completely failed afterwards, and the

* The subsequent history and death of this patient proved the case to be one of disseminated sclerosis.

parents gave up the treatment at the end of a week. I think it very likely that with perseverance and change of method this patient might be cured by suggestion; but it was disappointing not to have succeeded at once in a malady which is claimed by all authorities as affording convincing proof of the efficacy of hypnotism.

Consideration of the following cases may be useful:

Mrs. A——, aged forty, came under my care in the beginning of 1890 for intemperance. She had indulged to excess for seven or eight years, and was a confirmed drunkard. Her home was not very happy, and her husband and children were uncongenial. She was naturally a clever woman, but for many years had entirely given up useful employment and devoted her whole time, when sober, to reading novels. She was in the habit of drinking anything she could get in the way of wine, beer or spirits, and showed great cunning in the way she procured them. She had completely lost all interest in life, and had become thoroughly hardened and reckless. My success had been so gratifying that I undertook the case with some confidence, and named three weeks as the time it would probably be necessary to keep her under restraint and in the hands of a nurse. Mrs. A—— proved a good subject, and was influenced to the third degree. Suggestions were made in the direction of loss of craving and dislike for alcohol, and were repeated daily for three weeks. The patient was by that time quite a changed woman, had regained an interest in life, spoke affectionately of her husband and children, and had altogether softened to a surprising extent. She went away to stay with friends, and during her absence was always bright and cheerful; and though she had easy access to wines and spirits, she showed no inclination for them, but on the contrary, proclaimed her intention of never touching them again. She returned to her home after being away altogether four weeks, and she continued to keep steady for four or five weeks, during which time she paid me bi-weekly visits. Then I ceased to see her,

and soon heard that she had returned to her old ways. This case is a typical one, and I now know the reason hypnotism failed to exert more than a transitory effect. It was a bad case, and the home associations were antagonistic. Instead of keeping her away for only three weeks, she ought to have been under the charge of a nurse for at least three months, with only occasional visits to her home during that time. I have little doubt but that if this course had been followed the woman might have returned to her house and been temptation-proof in spite of ennui and opportunity. The change that was effected by three weeks' treatment justifies this inference, and the case is a warning against expecting too rapid results in difficult cases of dipsomania.

2. Mrs. W——, aged thirty, married, and with three children. She has been a patient for several years, and is fairly susceptible to ordinary medical treatment. One symptom, however, has always resisted the usual remedies. There was almost constant pain in the right ovarian region, which was tender on pressure; but examination by a specialist did not reveal anything abnormal, and the case was one, apparently, of ovarian irritation. I proposed hypnotism, and Mrs. W—— consented. She proved susceptible to the third degree, and I hypnotized her six times during three weeks. She completely lost the pain and tenderness, and though she has had ups and downs the last ten years, this particular symptom has never returned.

3. Mrs. B——, aged thirty-three, married, and with two children. She is of an anxious temperament, and has an invalidish husband who causes her great anxiety. She has a well-marked systolic bruit dependent on mitral regurgitation, following an attack of rheumatic fever thirteen years before. She was very short of breath, had pain and palpitation on exertion, and was so nervous as to be unable to drive in a hansom or use a lift. There were incessant spasmodic movements of the hands, and many other signs of nervous breakdown.

After various remedies, such as bromides, valerian, and digitalis, had been tried without much result, hypnotism was suggested and agreed to. Mrs. B—— was a good subject, though not a somnambulist. The heart's action became more regular and slower, and the twitching of the hands ceased. The treatment was continued daily for ten days, and the patient was then fairly well. She went abroad with her husband, and I hear she rides, cycles and goes about generally like a healthy woman. The valvular trouble is of course still there, but compensation is good, and the morbid nervous element has been suppressed by suggestion.

Mrs. B—— is one of several ladies who tell me that hypnotic suggestion has increased their courage and enabled them to cycle freely in traffic.

Even more disappointing than failure of suggestions to take effect are those cases where the treatment is strongly indicated, and yet cannot be applied on account of the insusceptibility of the patient.

A case in point is that of a schoolmaster who consulted me a few years ago on account of a miserable delusion which was wrecking his life. He was under the impression that the boys were always laughing at him, and the struggle he had to contain his anger and maintain his dignity was so intense that it was undermining his health. The idea would probably soon have been removed by suggestion, but, unfortunately, he proved absolutely insusceptible to hypnotism.

I have been called upon to treat two cases of 'phantom limb,' after amputation, by hypnotism. The treatment seems to be thoroughly indicated in such cases, and it was a great disappointment to find that neither patient was hypnotizable. The first patient was a gentleman of sixty, whose leg had been amputated a few weeks previously. He had intense pains, which he referred to the missing limb. I made many attempts to hypnotize him, but without result.

The second case was that of a colonial gentleman whose

arm had been badly shattered by a gun explosion, and had been amputated at the shoulder. For more than ten years he had suffered greatly, especially in damp weather, and he referred the pain to the thumb and fingers.

He also proved quite insusceptible. But I feel confident that hypnotic suggestion is the ideal treatment in such cases, for it exactly fits the indications. They correspond to hysterical joints, which are so troublesome to deal with. The pain, though referred to the joint or limb, depends upon central irritation, and is caused by the unhealthy condition of the cortical cells functioning the part.

Van Eeden tells me that he has seen a case of phantom limb and epilepsy cured by hypnotic suggestion at the Amsterdam Clinique. The patient had had his arm amputated after an injury, and developed traumatic epilepsy. Each fit was preceded by an aura which took the form of a forcible elevation of the amputated limb, accompanied by intense pain. This is a case in which, if hypnotism had failed, one would have urged trephining, and operation on the arm centre in the cortex.

The new theory of nervous action promulgated by Golgi and Ramón y Cajal throws light upon this condition. They have demonstrated that the neurons form combinations through their branches, or dendrons, not by continuity, but by position. When a nerve-current passes from one neuron to another, it does so by their respective dendrons interlocking or embracing, and the current is made in a manner analogous, probably, as Dr. Hedley thinks, to that seen in the coherers of electricians.

When the contact is not complete no nerve-current or impulse can pass, but a nerve cell once serving for the passage of nerve-currents undergoes an alteration which allows of a more ready passage of a similar current on a future occasion. Neurons tend to form combinations or 'sets'—to use the language of the compositor—and these 'sets' correspond with habits of thought and their accompanying actions.

Bodily conditions are registered in consciousness, and their physiological expression is the arrangement of the neurons. When the cause of the disturbance of function in a part is removed, the 'set' of the neurons should fall back into its normal position, and pain and discomfort cease to be registered in consciousness; but in some conditions of ill-health the neurons may remain in their abnormal condition, and the subjective symptoms therefore continue.

Thus, in the case of hysterical knee, some injury occurs to the joint, and swelling, stiffness and tenderness ensue, with pain on movement. These symptoms are registered in consciousness, and a corresponding 'set' of the neurons is the result.

Under ordinary circumstances, as the inflammation subsides the 'set' of the neurons tends to fall back into their old arrangement, which is associated in consciousness with a supple and painless joint. But it sometimes happens that the nervous arrangement does not change with the disappearance of the cause, and the idea of pain and disability continues and becomes fixed in the mind.

Successful treatment must operate centrally by restoring the neurons to their normal relationship and breaking up their faulty 'setting.' Much depends upon the capacity of change and of disjunction or conjunction in the field of contact. This is termed the plasticity of the neuron. Habit implies increased plasticity, and organic memory depends upon plasticity acquired for the good of the organism. In infancy and youth the connections are less rigidly set than in adult life, and consequently it is easy to direct and modify them.

NOTE.—The following cases further illustrate the use of hypnotic suggestion in general practice. During the recent epidemic of influenza, I was called to attend a young woman who, in addition to the usual symptoms, was suffering from congestion of the right lung and erysipelas of the face. She complained very much of frontal headache and pains in the limbs, and had not slept the preceding night. The eyes were completely occluded by the erysipelatous swelling, and she experienced much heat and aching in them. I asked her if she would like to sleep and get rid of some of her pain, and she naturally replied that there was nothing she more desired. The ordinary method was

out of the question, as she could see nothing, so I gently stroked her forehead and suggested drowsiness and sleep. This simple process rapidly induced somnolence and tranquillity, followed in less than ten minutes by a deep sleep, which lasted for two hours. The patient awoke greatly relieved by the physiological rest the system had enjoyed, and made a good recovery under the usual remedies. Of course, I do not contend that hypnotism is curative in erysipelas, congestion of the lungs, or any other acute disease; but from a number of experiences similar to the above I know that it quiets the nervous erethism which is so distressing a symptom in many acute cases, and puts the patient into a condition most favourable for recovery and for the action of drugs. I have found it useful as a palliative in cancer and other painful and incurable diseases. The following cases present features of interest:

1. Hystero-epilepsy for five years in a girl aged fourteen. Attacks were caused by touching the region of the right breast (a hysterogenic zone), and were characterized by convulsive movements of the right side. In addition, there were nearly daily attacks of what looked suspiciously like epilepsy, with occasional biting of the tongue, and followed by languor and drowsiness. The girl had been an in-patient at several hospitals without much benefit. After being hypnotized seven or eight times she began to improve. There is now no longer a hysterogenic zone, and she has had no fit of any kind for three months. The catamenia, which had been suppressed for six months, did not, however, reappear, in spite of suggestions made to that effect.

The two last cases I shall give are not examples of brilliant cures, but illustrate the importance of not promising too much from the treatment.

2. Miss H—— has been a chronic invalid almost since childhood. She is forty years of age, and has anchylosis of the right hip-joint, following hip-joint disease and lateral curvature of the spine. She is of hysterical and melancholy temperament, and her mental powers seem to have atrophied *pari passu* with her disused muscles. A year's perseverance in the treatment has enabled her to find some enjoyment in life; she is able to walk over a mile without much fatigue, and to play the violin for nearly an hour at a time. Previously for some months she had been barely able to move about the house, and it is years since she was able to walk a quarter of a mile. Neither had she been able for a long period to play, partly because of invincible habitude, and partly from the fatigue attendant on the slightest effort.

3. Miss E—— was sent to me in October suffering from hysterical right hemiplegia of a year's standing. It came on suddenly after her mother's death, and she had had repeated relapses after apparent improvement. She fell sometimes into the third and sometimes the fourth degee of hypnosis, and in this condition friction was applied to the paretic side, and suggestions made. She improved but slowly, and after twelve operations suffered from a relapse, and was confined to her bed completely helpless for a week. On her return to me I found the right arm and leg much colder than the left, and the reflexes on that side increased. Perseverance in the treatment for three months has produced a decided improvement: the right leg is nearly as warm and strong as the left, and her general health has greatly improved. One would almost have felt justified in expecting more rapidly curative results in this case, and the relapse whilst undergoing treatment was

disappointing. It illustrates the point I have so frequently alluded to, that pronouncedly hysterical persons are by no means the best subjects for this treatment.

My appreciation of the efficacy of drugs has been increased since studying hypnotic suggestion; for I have seen on several occasions a properly selected remedy remove a symptom which suggestion had left untouched. Dr. Van Eeden has shown how the beneficial effects of massage and Swedish gymnastics are increased in certain cases by being combined with Dr. Liébeault's system.

That hypnotic suggestion is destined to play henceforth an important part in the treatment of disease and the alleviation of human suffering is evident, and enlarged observation will show what it can and what it cannot do. Its future in this country depends on the attitude the medical profession assumes towards it during the next few years. If the attitude is a wise one, and the utility of hypnotism in treating certain diseases is recognised, and its practice given an honourable position, we shall see benefit conferred on humanity. Hypnotism affords special scope for quackery, and if its legitimate possessors refuse to use it, we shall probably see a class of undesirable practitioners arise whose interests in it will not coincide with those of their patients or the profession.

NOTE 1.—FOR PAGE 27.

I AM informed on the best authority that in the initiatory rites of several secret societies the candidate is submitted to a somewhat similar ordeal. He is told that he must submit to be bled. His eyes are blindfolded, his arm is pricked, and a stream of warm water is allowed to trickle down it.

The surroundings at the same time being mysterious and awe-inspiring, a very great effect is produced on nervous and sensitive subjects. Syncope and nervous exhaustion not uncommonly follow the ceremony, and the new member may be made ill for days.

The rite is, no doubt, an example of the survival of the form after the unpleasant reality has, in deference to civilization, been allowed to fall into disuse.

An amusing experiment is described by Dr. Yung, *privat docent* of Geneva, which forcibly displays the power of suggestion without hypnotism. He calls it 'the experiment with magnetized cards,' and he carries it out as follows: With a grave face and serious manner he pro-

ceeds to give a short account of 'animal magnetism,' and to explain how the 'subtle fluid' can be made to affect even inert substances. Having thus aroused 'expectant attention,' he carefully arranges a few cards on the table and makes 'magnetic' passes over them. This process, he assures his audience, charges the cards with his magnetism, and makes them different to any other cards, so that if a person touches one of them he will change its polarity, and it will thus be distinguishable to his touch from the others. He then leaves the room, and a bystander touches one of the cards. Dr. Yung, on his return, makes a few passes over them and finally picks out the card which has been touched, saying that he feels contact with it sends a nervous thrill up his arm like an electric shock.

But he adds there is nothing wonderful in this, as anyone will experience the same thing. The challenge is accepted, and probably the most sceptical person in the room goes through the same pantomime of magnetizing the cards with a look of scornful contempt on his face. No card is touched, and he is told on his return not to make a guess, but to really try if he can detect a difference between one card and another. In nearly every instance Dr. Yung found a difference was said to be felt, and whatever card was indicated was declared to be the right one. The experimenter is shut out of the room a second and a third time, and it is nearly always found that by the third time the subject will declare he undoubtedly feels a very strong nervous shock of the kind described by Dr. Yung. Of course, Dr. Yung had a confederate who, by an agreed-upon signal, informed him of the card which had been touched. He has tried this experiment on about 800 persons, many of whom were medical men and scientific students, and in nine cases out of ten he has elicited by pure suggestion the sensations he described.

I have repeated the experiment in about a score of cases, and in nearly every instance have obtained a like result. One subject, a particularly wide-awake American, assured

me at the third trial that the shock was quite as strong as that received from a powerful static battery which he had just been testing.

Note 2.—Braid of Manchester.

James Braid used to throw his patients into a kind of sleep or trance by making them fix their eyes and attention on a bright object—generally his lancet-case—held a few inches above the eyes. He found this caused fatigue of sight and abstraction of mind, which in nearly all cases induced the condition he termed *hypnotism*.

He practised his system successfully for many years at Manchester, and wrote several books in which he fully explained it.

But it seems to have died with him, and it is only now that *suggestion* with hypnotism has come so prominently before the profession that his works begin to be largely read. The most important one, 'Neurypnology' (London, 1852), has been recently translated into French by Monsieur Jules Simon—an almost unique honour, I imagine, for a foreign medical author nearly thirty years after his death.*

Braid found hypnotism increased the heart's action to such an extent that he warned medical men against using it when heart disease was suspected. He found it impossible to get children to keep their eyes fixed on his lancet-case for the necessary four or five minutes, and therefore regarded them as insusceptible. We have seen, on the other hand, that suggestion finds its best subjects in children between the ages of three and fourteen, and in heart disease it is one of the most successful means of calming and reducing irregular heart action. Braid went near to discovering the truth which Liébeault, a few years afterwards, thought out, and introduced to the world.

* Braid died in 1860, the year in which Dr. Liébeault opened his dispensary at Nancy. So though unrepresented in England, he found a follower abroad who was possessed of a 'double portion of his spirit.'

Note 3.—Duration of Hypnotic Sleep.

In order to arrive at the solution of this question, Professor Bernheim allowed many of his patients to 'have their sleep out.' He found its average duration was three or four hours, but, as with natural sleep, it varied with individuals and circumstances.

On several occasions it lasted fifteen, and once eighteen, hours. In all cases the patients awoke fresh and comfortable.

Note 4.—Dr. Luys' Rotating Mirror, and Dr. Ochorowicz's Hypnoscope.

The mirror designed by Dr. Luys, of La Charité, is used in dispensaries and hospitals when it is desired to hypnotize a large number of persons in a short space of time. It consists of a rapidly revolving mirror mounted on a stand, and it is found that gazing at this quickly dazzles the sight and produces hypnosis in susceptible subjects. By its means a roomful of people may sometimes be hypnotized at once, and the suggestions can be applied at leisure. There is a large sale of these instruments in Paris, but in private practice I think they would not be found very effectual. Dr. Liébeault and others frequently operate on thirty or forty patients in a forenoon by the ordinary method without fatigue, so I fail to see the object of this plan of hypnotizing people wholesale.

Considerable experience with Luys' mirror has not altered my opinion as to its utility. In one instance, an hysterical young woman, whom I cured of very obstinate hiccough (it had been almost incessant for seven years) by suggestion, was hypnotized by gazing for twenty minutes at the mirror after other methods had failed; but her case is almost an isolated one in my experience. Though Dr. Luys stated that everyone goes to sleep after looking at the mirror for half an hour at the longest, I have seen several patients, who wished to be influenced, gaze at it steadily

for nearly an hour without any result except a headache. I have seen it produce most violent palpitation, and altogether should advise caution in the use of the instrument.*

Dr. Ochorowicz, late Professor of Physiology at Lemburg, has devised an instrument for testing hypnotic susceptibility, which he calls the hypnoscope. It consists of a steel magnet bent in the form of a ring, which is placed on the patient's finger. He finds susceptible persons experience a sensation of numbness and stiffness in the part after wearing the instrument for a short time, and the finger is often rendered rigid and immovable. Dr. Ochorowicz himself seems to think this effect is the result of suggestion, and no doubt a patient who is so easily influenced by the imagination would be a good subject for the treatment. But I imagine that many persons who are sufficiently susceptible to hypnotism to benefit from suggestion would be quite insensitive to such action. Readers of Braid's 'Neurypnology' will remember how he paid a visit to a lady who announced herself as so affected by a magnet that she knew at once when there was one anywhere near her. Braid sat close to her for an hour with a most powerful magnet in his pocket within a few inches of her, but she experienced no discomfort, *because she did not know it was there*. I have frequently produced many curious local subjective symptoms in impressionable persons by passing a magnet over a limb, but always of the nature I had previously suggested.

NOTE 5.—THEORY OF PROFESSOR DELBŒUF.

The late Dr. Delbœuf, of Liége, whose experiment on the cauterized arm has been referred to (p. 66), and whose eye case has also been quoted (p. 289), puts forward a theory to account for this action of suggestion on the functions of

* I am frequently asked where the instrument can be bought. Until recently one had to get it from Paris, but now Mr. Thistleton, medical electrician, 1, Old Quebec Street, London, W., keeps a stock of rotating mirrors.

organic life. He supposes that under ordinary circumstances our attention is concentrated upon external things, from which come our more vivid impressions—the life of relation. The vegetative functions are so established that they go on automatically and unconsciously, and it is only under exceptional circumstances that we become acquainted with the working of organic life; *e.g.*, lying awake at night, we become conscious of the movements of the heart, and in illness we are frequently made unpleasantly cognisant of functions at other times unfelt. But though in the progress of evolution it has been found expedient that the functions of organic life should be carried on automatically by the lower departments of the cerebro-spinal system, in order that all our attention may be devoted to accommodating ourselves to the environment, the highest centres have not yet entirely lost control over those below them, and may under certain circumstances resume, on occasion, the power which they had ceased to exercise. It is well, under ordinary circumstances, that organic life should be carried on automatically; but it is conceivable that conditions may arise in which the interference of the suzerain may be necessary. It is in these cases, according to Professor Delbœuf, that hypnotism plays such an important part. The hypnotized person is more or less cut off from the life of relation, and the attention, being set free from consideration of the environment, can be directed inwards and made to concentrate itself for a time on the organic functions: the mind is thus enabled to resume its knowledge and the will its control.

On this theory it is possible to understand the different degrees of control over their functions exercised by different individuals. On the one hand we see or hear of exceptional cases like that of Colonel Townshend, in which a person is able, apparently, to exercise some control over his organic functions in his ordinary waking state; and others in which such a result may be brought about by special psychical preparation — *e.g.*, the Indian fakirs. The theory explains the facility with which we produce

curative effects in certain patients who are only slightly influenced by hypnotism, whilst in others our suggestions only affect functions, and relieve symptoms when the hypnotic sleep is extremely profound.

Note 6.—Theory of Mr. F. W. H. Myers.

Mr. F. W. H. Myers has for many years made a careful study of hypnotism from a psychical point of view, and his researches on the subconscious self, or subliminal consciousness, are embodied in the Proceedings of the Society for Psychical Research.

He was invited to address the members of the British Medical Association at Edinburgh in 1898, in the section of Psychological Medicine, and he there briefly expounded his theory, which is this: Ordinary consciousness makes up but a small part of a man's personality. 'Beneath the threshold of working consciousness there lies, not merely an unconscious complex of organic processes, but an intelligent vital control.' He supposes that this subliminal consciousness is evoked by the hypnotist, who is thus enabled, as it were, to tap a deeper stratum of being, which is more independent of passing impressions and environment than the ordinary strata of consciousness. In hysteria with anæsthesia, restricted field of vision and blunted muscular sense, we see a curtailment or submergence of the normal self, whereas in the manifestations of genius we have its enlargement or emergence.

It is this higher level which is spoken of as inspiration, and which is developed in all great poets, artists and teachers who are illuminated by the flash of genius, or an emergence of faculty from the subconscious strata.

Mr. Myers is a poet as well as a psychologist, and might, I suppose, be called a pantheist. He believes in a 'world-soul,' with which our higher nature is in communion, more or less. This, however, is not the place to expound the depths of his philosophy, or to praise the beauty of the language in which his ideas are expressed.

Such problems have always exercised humanity, and there is nothing quite new under the sun.

'Subliminal consciousness' in its omniscience and omnipotence appears to take the place occupied by the Archeus in Van Helmont's system, only the Archeus was of a more material type than Mr. Myers' subliminal self. It required drastic treatment at times; for instance, Van Helmont says, 'Dropsy is not due to an organic lesion of the liver, but to the anger of the renal Archeus, who has lost his temper and refuses to work. One way of reducing him to order is to terrify him, and this may be done by tying a snake round the patient's waist, and applying toads to the region of the kidneys.'*

Note 7.—Some Phenomena of Hypnotic Somnambulism.

Many extraordinary and, at the present time, inexplicable phenomena can be produced in subjects who attain the last degree of hypnotic somnambulism.

Such persons are but rarely met with, and are, I believe, always of hysterical temperament, which is generally combined with a tendency to phthisis, scrofula, or other chronic disease.

These phenomena, as has been already said, are of purely psychological interest, and should be kept entirely distinct from therapeutic suggestion.

Among Dr. Liébeault's patients at Nancy is a young woman named Camille, a favourite subject for experiment, as she readily falls into the most profound state of hypnotic somnambulism.

Like many hysterical persons, she takes a pride in her infirmity, and therefore, without being oversceptical, one may wish to verify the experiments tried on her. One of the most curious of these is the production of *negative hallucinations* by suggestion. Camille, and one or two other persons of the same nervous temperament,

* 'Medical History from the Earliest Times.' Withington, Scientific Press Series, 1894.

would be told that on waking they would not see So-and-so, though he might speak to her, touch her, and even prick or pinch her, and the suggestion was realized. Or they would be told that the door was no longer existing, in which case, though apparently quite awake, they would seek in vain to cross the threshold until the spell was removed.

On my return to London I was fortunate enough to meet a lady who takes a great interest in the subject, and is at the same time susceptible of being thrown into the most advanced stages of hypnotic somnambulism. Her husband is a man of science, and also much interested in hypnotism. They were both quite ignorant of the phenomena I wished to produce, and the conditions therefore were perfectly satisfactory.

Mrs. H—— is about thirty years of age, small, slight, and a blonde. She is highly nervous, and occasionally hysterical, but she enjoys good health, is intelligent, and active in her household duties. On the first occasion I tried to develop a negative hallucination, her husband was confined to the room with a bad cold, and was sitting by the fire in an armchair a few feet from her. I hypnotized her, and told her that on waking she would not see him, would not hear him if he spoke to her, and would not feel him if he touched her. All this was literally realized. She was apparently wide awake, and yet when I asked her where her husband was she said she didn't know, but thought he had gone upstairs, and would be down very soon. He spoke to her, calling her by name, and asked her to get his medicine, to stir the fire, what there was for supper, and a number of other questions. She gave not a sign of having heard; in fact, she evidently did not hear him, though she conversed with me intercurrently quite rationally. Mr. H—— then approached her, touched her hand, sat down beside her, and talked; but evidently for her he had ceased to exist, as she betrayed not the faintest consciousness of his presence. I then asked Mr. H—— to speak impersonally, and he said, 'Mrs. H—— will now go to the table, take up the doctor's gloves, and

try them on.' She did not appear to hear, but in a few moments she got up, went to the table, and tried on my gloves—a thing she would never have thought of doing of her own initiative. I asked her why she did this, and she replied, 'I don't know; I thought I should like to.' She was not aware that the impulse proceeded from another. When I blew on her eyes, and said, 'Mrs. H——, there is your husband close beside you, and you can see him now,' she looked fixedly at his chair for a moment, and then said, 'Yes, I see him now; but where was he a minute ago?' adding, 'At first he looked small and indistinct, but now it is all right.'* We know we may look at a thing and yet not see it when in a 'brown study,' or preoccupied with something. A familiar example of this is afforded by observing how absent-minded people pass their friends in the street without recognition, though their eyes may dwell on them for some time. Afterwards they will deny having seen them, and truly they have not. 'Eyes have they, but they see not.' A physical impression has been made on the retina, but it has not undergone that cortical co-ordination or registration in consciousness without which there can be no perception.

I had only learnt that morning, from reading an article by Professor Liégeois,† the curious fact that in hypnotic somnambulism the subject will carry out a suggestion made by a person whom she is prevented, by some inhibitory nerve-action, from apparently either seeing or hearing. The same lady kindly allowed me to try other simple experiments on her. She was ignorant of the

* Binet and Féré, *op. cit.*, p. 311, relate a convincing experiment showing the reality of this psychical blindness. A subject had on each side of the mammary region a hysterogenic zone, pressure on which immediately produced an hysterical attack. One of the physicians rendered himself invisible by suggestion, and at the same time destroyed the sensation of contact on his approach. A strong pressure on the zones then failed to produce any attack, nor did she make any effort to repel the experimenter, but only complained of a vague sense of oppression. On the other hand, she recoiled in terror when another person put his hand near these zones.

† 'Un Nouvel État Psychologique,' *Revue de l'Hypnotisme*, August, 1888.

nature of them, and only stipulated that they should not make her appear ridiculous or cause much pain. When in the hypnotic sleep I gently touched and kept my forefinger on a small surface of the wrist, saying while I did so, 'Poor Mrs. H—— has a nasty burn on her wrist, probably from some boiling water; the place is very red, and rather painful.' In a few minutes I awakened her, and she immediately began rubbing her wrist, as if in pain there. On my asking her what was the matter, she replied, 'I think I must have spilt some boiling water on my wrist; it feels as if I had burnt it.' On looking at the spot, there was a very perceptible patch of redness about the size of a sixpence, and every moment this became more defined and angry-looking. As the pain was increasing, it would have been a breach of our agreement to protract the experiment, so I hypnotized her once more, and told her that there was no burn, and that the redness and pain would be quite gone when she awoke. In point of fact, a very short time was sufficient to disperse the morbid appearance, and on reawakening her there was no complaint of discomfort. The same lady after the first operation complained of chilliness and stiffness, but I had only to suggest on future occasions that she was not to feel these unpleasant symptoms to ensure her not being troubled with them.

These experiments belong in no way to therapeutic suggestion, but are of interest, as they show how exactly the phenomena produced at Nancy may be reproduced by experiment in England.

NOTE 8.—DR. LIÉBEAULT'S CLASSIFICATION OF HYPNOTIC SLEEP.

First Degree.—The patient feels a heaviness of the eyelids and a general drowsiness.

Second Degree.—This is characterized by suggestive catalepsy. When the operator places the arm in a certain position, and says it is to remain there, it is impossible for the patient to put it down. It remains rigid

and fixed for a much longer time than would be possible in a natural state. In these two degrees consciousness remains almost complete, and often the patient denies having been in the hypnotic state because he has heard and remembers every word which has been spoken to him. A very large proportion of people never pass beyond this stage.

Third Degree.—In this the subject is also conscious of everything going on around him to a certain extent, and hears every word addressed to him; but he is oppressed by great sleepiness. An action communicated to a limb is automatically continued. If the arm is rotated to begin with, it goes on turning until the operator directs its stoppage.

Fourth Degree.—In the fourth degree of hypnotic sleep the patient ceases to be in relation with the outer world. He hears only what is said to him by the operator.

The *Fifth* and *Sixth Degrees*, according to Liébeault, constitute somnambulism. In the former, recollection of what occurred during sleep is indistinct and recalled with difficulty; in the latter, the patient is unable to recall *spontaneously* anything which has occurred while asleep. All the phenomena of post-hypnotic suggestion can be induced in this condition, and it presents features of extraordinary interest to the psychologist.

Note 9.—Method of Public Performers.

Though, in deference to public sentiment, the travelling 'professors' style themselves hypnotists, it is easy to see that they do so somewhat under protest, and that they much prefer the old name of 'mesmerism,' or, better still, 'animal magnetism.'

Their method is the same all the world over. A certain number of previously-hypnotized subjects are scattered among the audience, and when the lecturer asks for persons to experiment on, these make a rush for the platform, and form a nucleus on which to work. Probably a few *boná-fide* strangers will lend themselves for experiment, and one way and another the platform will be well filled

with candidates. The lecturer gives to each person a bright disc, which he is to look at steadily. In a few minutes he goes round, closes the eyes, and tells the subject that he is unable to open them. If he opens them, he is sent back to his seat among the audience; if not, he is reserved for further use, and is given a seat on the platform. A favourite plan with the experimenter is now to open the subject's mouth to its widest extent, turn him round so as to face the audience, and tell him he is unable to shut it. A friend of mine, a doctor in good practice, was so treated in a foreign watering place, and his feelings when he was thus made a laughing-stock of a large assemblage of people were not enviable. After these experiments in inhibiting voluntary motor action, the lecturer will go on to produce hallucinations of the senses, and will amuse his audience by showing what antics a human being can be made to perform when he has been deprived of the use of the higher brain functions. He can be made to think himself a general at the head of his army in battle, a school-boy being flogged, or an animal at the Zoological Gardens. Whatever he is told to believe is at once acted upon, and as the lecturer's object is to cause amusement, he finds it advantageous to make the actions outrageous, and to alternate the imaginary changes of condition as rapidly as possible. It is no wonder, therefore, that the unfortunate subjects complain the next day of malaise and mental confusion, and it is fortunate if no graver results follow.

The performance of such a person has about as much relation to psycho-therapeutics as the antics of a merry-andrew at a fair have to the practice of a Court physician. That such things should have been tolerated will probably be a subject of astonishment to our descendants.

A friend of mine a few years ago paid heavily for taking one of these men at his own valuation. He was much struck by the phenomena shown at a public performance, and had a conversation with the 'professor' afterwards, which further impressed him. The next day at his club

some of his friends said the whole thing was a fraud, and laughed at Mr. X—— for believing the performance genuine. My friend waxed warm in argument, and offered to back his opinion by betting £100 that the 'professor' would hypnotize two persons out of any ten selected by the unbelievers.

The bet was taken up by two members of the club, and Mr. X—— stood to win or lose £200.

A supper was arranged, to which the 'professor' was invited, and ten young men selected from a South London football team were brought in after supper as subjects. Not one of them proved hypnotizable, and my friend lost his money.

The conditions were very unfair, as the young men had been told to resist: and to attempt to hypnotize a number of unwilling strangers after supper among a crowd of sceptical lookers-on was a task which no wise man would undertake. My experience would lead me to reckon that, under suitable conditions, eight out of the ten would have been more or less influenced; and probably two or three, after a trial or two, would have proved somnambulic.

Note 10.—Resolutions adopted at the Paris Congress.

The following resolutions were agreed to at the first International Congress of Physicians and Jurists on Hypnotism held in Paris, 1889:

'This Congress recognises the danger of public exhibitions of magnetism and hypnotism, and deeming that the therapeutic application of hypnotism has become a branch of the science of medicine, that its official teaching is the province of psychiatry, votes the following resolutions:

'1. Public exhibitions of hypnotism and magnetism should be forbidden by the administrative authorities in the interest of public hygiene and public morals.

'2. The employment of hypnotism as a curative agent should be subject to the laws and restrictions which regulate medical practice generally.

'3. It is desirable that the study of hypnotism and of its therapeutic application be introduced into the curriculum of medical sciences.'

The following schedule (pp. 346, 347) has been sent to all physicians who have sent in their names as practising hypnotism. The immense practical value of the statistics to be thus collected will be recognised at a glance.

INTERNATIONAL STATISTICS OF HYPNOTIC IMPRESSIONABILITY AND OF SUGGESTIVE PSYCHO-THERAPEUTICS.

The following schedule is framed with the object of elucidating the results of hypnotic treatment by comparative statistics.

'*a*. The proportion of persons who are susceptible to hypnotic influence.

'*b*. The degree of impressionability and its relation to the age, sex, constitution and temperament of the subject, and the method of hypnotizing adopted.

'*c*. The value of hypnotic suggestion as a therapeutic agent tested by the amount of success and number of failures, by the duration and completeness of the cures, ameliorations,' etc.

This inquiry is extremely important, because authorities are not agreed on the subject, and we therefore beg our colleagues who use hypnotism either as a means of cure or for scientific investigation to fill in the enclosed papers as completely and carefully as possible.

Please give the degree of hypnotism attained, and for the purpose of classification observe the following definitions and characteristics:

I. *Light Sleep*.—Feeling of fatigue. The patient's will-power is either unaffected or is only slightly modified. It is often difficult or impossible to open the eyes. The subject on awaking remembers everything that has happened, and does not experience the sensation of having slept.

II. *Profound Sleep*.—The patient's will is either partially or completely in abeyance. The eyes are generally closed,

SCHEDULE.

Somme totale des personnes.	Hommes (= *h*).	Femmes (= *f*).	Age (approximatif) : *a* = 1-10. *b* = 10-20. *c* = 20-30. *d* = 30-40. *e* = 40-50. *f* = 50-60. *g* = 60-70. *h* = 70-100.	Dégré d'influence hypnotique. O. Refractaires. I. Sommeil leger. II. Sommeil profond. III. Somnambulisme.	Méthodes employées, $\alpha\ \beta\ \gamma$ o.	Effet nul.	Amélioration légère ou passagère.	Amélioration très décidée.	Guérisons.	Récidives.	Durée des succès.	Ont abandonné le médicin devant traitement fini.	Résultat inconnu.	Nombre des séances hypnotiques.	Remarques.	Nom, titre, fonction du correspondant : Domicile adresse du correspondant :
																I. Personnes saines.
																II. Personnes malades.
																A. Maladies du système nerveux. (Affections organiques.) Affections traitées.
																B. Maladies mentales.
																C. Grandes névroses : (*a*) epilepsie, névrasthénie, tétanie, chorée, etc. (*b*) affections hysterique.
																D. Troubles névropathiques diverses : (*a*) anesthésie, hyperesthésie, crampes, convulsions diverses. Névralgies. Céphalgie habituelle. Migraine, etc. (*b*) Paralysies fonctionelles, parésies. (*c*) Autres troubles nerveux, incontinence d'urine, somnambulisme nocturne,

																	Onanisme. Hypochondrie. Agoraphobie. Impuissance (faiblesse) psychique. Habitudes perverses.
																	E. Troubles fonctionelles des appareils ou systèmes en consequence des (*a*) Maladies d'organization (constitution) : arthrite, anémie, maladie tuberculeuse, consécutifs à syphilis. (*b*) Affections rhumatismales : articulaires, musculaires. (*c*) Troubles gastro-intestinaux : vomissements, catarrhes, nerveux (crampes, manque d'appétit, etc.). (*f*) Consécutifs au maladies d'infection. (*g*) Liés à des maladies externes.
																	F. Anesthésie chirurgicale.
																	G. Diminution du fièvre.
																	H. Troubles de la menstruation. Chlorose.
																	J. Autres affections non citées.
																	K. Remarques.
																	Expériences de Stigmatisation, etc.

but sometimes remain open. Memory on awaking is either lost or incomplete, and he feels more or less the sensation of having slept.

III. *Somnambulism.*—Complete amnesia on awaking, and possibility of realizing hallucinations and other hypnotic and post-hypnotic suggestions.

The sign O signifies the waking state.

Please indicate the method employed by the following signs:

a. Method of Braid and Charcot. Physical means. Vivid sensory impressions (light, sound, etc.). Fixation of the eyes with a brilliant object. Pressure on or friction of certain regions of the body (hypnogenic zones). Monotonous sensory impressions, etc.

β. Method of Liébeault and Bernheim. Suggestion: the method adopted by the school of Nancy.

γ. Combined method—*a* employed systematically in conjunction with *β*.

Forms to be obtained from, and details to be sent to, Dr. Von Schrenk-Notzing, Munich.

Note 11.—Experiments in Auto-Suggestion.

Dr. Coste de Lagrave, surgeon-major in the French army, contributed an interesting paper to the International Congress on auto-suggestion, and related several experiments he has made on himself during the last few years.

By practice he acquired the power of being able to sleep at will, and of awaking at a definite time. To effect this he only had to lie down, and fix his attention on sleep, and on the idea that he would awake after a certain number of minutes. In a short time he obtained such self-control that he could get five or six distinct sleeps, and as many distinct awakenings, in the course of an hour. He also succeeded in producing dreams of the character he wished, and in evoking sensory delusions and hallucinations to such an extent that he became alarmed, lest the condition thus induced should become permanent. He was able to apply auto-suggestion in a curative direction, and thus to

relieve himself of colic, gastrodynia, and the like. He did this by closing his eyes, and concentrating his thoughts on the organ he wished to affect. In from a quarter to half an hour he generally succeeded in getting rid of the pain. On one occasion, when riding with troops, he suffered greatly from cold feet, and he tried the effect of auto-suggestion. He closed his eyes, and induced a state of drowsiness, in which he directed his thoughts to his feet, which he wished to become warm. In less than half an hour he was conscious of a feeling of warmth in them, and as long as he kept his attention fixed there they continued so; but very soon they became cold again when he allowed his thoughts to dwell on other things, showing, as he thinks, that the sensation of warmth depended on mental influence and mind concentration. In subsequent experiments he produced the desired result in a shorter time, and he found that the sensation of warmth was not merely subjective, for on removing his boots he felt the previously cold feet warm to the touch, thus getting the same effect as is nearly always demonstrable in ordinary hypnotic practice.

He relates a curious experience of auto-suggestion in nervous prostration. He had been invalided home from Tonkin for dysentery, and for a year had been so prostrated by weakness that he was unable to walk a mile in the course of a day. One night he suggested to himself increased muscular and nervous force, and ability to walk without fatigue. The next day he walked over six miles without difficulty; but, unfortunately, he does not mention in his paper whether this effort was followed by reaction, or whether the improvement was permanent.

Dr. de Lagrave's experiments open up an interesting field of research, and if his experience is corroborated by that of other scientific observers, it will throw light on a number of mental phenomena connected with directed self-consciousness, which are at present surrounded with a degree of mysticism. The yogis and fakirs of India assert that they can obtain remarkable control over their bodily organs and functions by contemplation, introspec-

tion, and other mental exercises; and there is little doubt that many of their achievements are the result of auto-hypnotism and auto-suggestion.

Note 12.—Hypnotization of Animals.

Dr. Gerald Yeo, late Professor of Physiology at King's College, read a very interesting paper before the College Society in 1883 ('The Nervous Mechanism of Hypnotism'), in which he propounded some interesting theories on the subject of hypnotic phenomena, and illustrated them by experiments on animals. He showed how animals of such diverse organization as crayfish, frogs, fowls and guinea-pigs could be easily hypnotized by monotonous continuous stimulation, and made to remain motionless and unresponsive to ordinary stimulation. He induced this state by firmly fixing them in one position for a few minutes, and then gently removing the restraining influence, when it was found the animals continued in that position, however abnormal, for several minutes. Kircher's experiment with the domestic fowl is the most familiar example of hypnotic effect in animals. If a chalk line is drawn and the bird held for a few seconds with its beak on this line, it will be found that the creature remains in that position for several minutes. Dr. Yeo, however, says that the line is unnecessary in performing this experiment. Dr. Ralph Vincent (*op. cit.*) relates various experiments he has made on hypnotized cats, rabbits, toads, and other animals.

The plan of changing the nest of a sitting hen, familiar to farmers, probably depends on hypnotism for its success. The fowl's head is firmly held under its wing for a few minutes, and she is carried from one nest to another. She seems ignorant of the change, and continues sitting on the new set of eggs until they are hatched, or she is again removed to another nest in the same way. The drowsy condition induced in many animals by gentle friction of the forehead is a matter of common observation; and I have frequently seen negroes in South America reduced

to a condition of drowsiness verging on somnambulism by the gentle stroking of the head and manipulation of the hair which they seem to be so fond of at the hands of their womankind.

Note 13.—Treatment by Transfer.

Dr. Luys, physician to La Charité Hospital, Paris, and a well-known physiologist, has recently introduced a novel kind of treatment of which he expects great things, and which, as he told me, he thinks will supersede hypnotism. In company with Dr. Kingsbury, I took several opportunities in 1890 of visiting his clinique and seeing his method.

Dr. Luys and his assistants were most kind, and readily showed us the curious experiments described in the *Fortnightly Review* for August, 1890. Several patients were undergoing the new treatment, and we had the opportunity of watching their progress for three or four days, and of questioning them as to their feelings and symptoms. Many of them spoke with enthusiasm of the progress they were making, and in a few cases it was possible to note an improvement from day to day. The process is simple enough. The patient is directed to sit down and grasp the hands of a profoundly hypnotized subject, and Dr. Luys passes a heavy magnetized bar of steel up and down both sitters' bodies, especially pressing on the cardiac and epigastric areas. A shiver is seen to pass through the hypnotized subject's frame, and he begins to complain of suffering from the same symptoms as the patient has experienced. The doctor questions him as to the symptoms, and then assures him that they will be cured and not return—much in the same way as the hypnotizer deals with his patients. In the meantime the patient looks on and sees the transferee writhing in his pains, and imitating his voice, gait, gestures and demeanour generally. If he is an imaginative person, it is quite likely that he feels better from witnessing this vicarious suffering. When the doctor thinks it is enough, he tells

the subject to wake up and to feel no more pain, and as a matter of fact he does not remember on waking what he has gone through in the somnambulic state, but goes away feeling apparently none the worse, and gratified by a gratuity from the patient whose disease he has shared. Dr. Luys contends that the subject not only shares the disease, but partakes of the personality of the patient, and demonstrates this by showing how a female sitter will assume a masculine voice and carriage when sitting for a male patient, and will complain of the beard being pulled if one approaches the face too closely. It is not a little surprising in this age of science to find a man of Dr. Luys' undoubted honesty and attainments seriously upholding practice of this kind. One is taken back to the time of Perkins and his metallic tractors to find a parallel for what is now taking place in Paris; and be it remembered that remarkable cures did follow the application of Perkins' instruments and of the wooden imitations which the physicians of Bath tested in their hospital practice.*

What, then, is the explanation of the results which follow such methods of treatment? It is summed up in the word 'suggestion.' The imagination is profoundly affected by the hope and expectation of cure, and this in itself is sufficient to bring about a healthy change in the hypochondriacal, hysterical, and *malades imaginaires*. But among the patients we questioned were some who suffered from well-defined organic disease; one gentleman affected with aortic insufficiency assured me that since his visits to Dr. Luys he had recovered his appetite, had slept well, and been able to walk uphill and upstairs, whereas previously he had been sleepless, without appetite, and almost bedridden. A man suffering from paralysis agitans declared he felt a different being, but as far as we could see there was no lessening of his tremor, though the young woman who acted as his transfer reproduced his disordered movements most faithfully. It is evident

* 'Influence of the Imagination in Health and Disease,' by Dr. Hack Tuke.

that in nearly all diseases there exist symptoms—often the most painful part of the malady—of functional nervous origin, and it is these symptoms which are largely met by hypnotic suggestion and other treatments which appeal to the imagination or the subconscious mind. I consider that it is the duty of a physician to relieve suffering in any way, as long as it is not immoral or hurtful; but no one visiting La Charité Hospital can say that the treatment by transfer, as practised there, is free from terrible abuses. It is a sad sight to see to what a deplorable condition of mental instability and inanity the unfortunate subjects have been reduced by continual hypnotization and experiments. Of course, the experiments carried out on such subjects, and under such hysterical conditions as exist in Dr. Luys' clinique, are valueless from a scientific point of view; and the phenomena he obtains from the action of the magnet, different coloured balls, and with medicines at a distance, have been sought for in vain by other investigators. I have found my subjects perfectly insusceptible to the magnet, until I have told two or three of them that contact with it will always produce pain in the part touched; henceforth they have always realized my suggestion, and complain bitterly when touched by it, or by any cold metallic substance. When one considers that the personality of a subject in the profounder hypnotic states is in complete abeyance, and that his mind is a blank page, to be written on at the dictation of the hypnotizer, we see how absolutely necessary it is to guard against conscious and unconscious simulation, and how utterly Dr. Luys' experiments are wanting in the only conditions which could render them of any value.

As bearing upon the above remarks, I may state that I purposely asked Dr. Luys if the magnet influenced all somnambulists in the same way, and he answered that it did. If he had been more cautious, and had replied that only some subjects were sensitive, one would have been more inclined to believe in the genuineness of his results.

The only way of testing the so-called magnetic sense described by Reichenbach is by the electro-magnet, which can be 'made' or 'unmade' instantaneously in a manner impossible for the subject to guess by ordinary sensuous impressions. The inquirer will find in the first volume of *The Proceedings of the Society for Psychical Research* a report of some experiments made to determine the existence of this sense. The experiments were carried out under rigorous scientific conditions, and proved that certain persons do possess the faculty of perceiving certain effects from the poles of an electro-magnet when in action. But from this to the propositions laid down by Luys is a very long step.

The use of the magnet in medical practice is nothing new. Hippocrates believed in its virtues, and recommended its employment in painful diseases (Laycock). Throughout the Middle Ages its efficacy was a matter of general belief, and Mesmer and his followers saw an analogy between animal and telluric magnetism. It has been left for Charcot and his school to claim physical reactions from the use of the magnet in our own time. Whether such reactions depend upon pure suggestion, as asserted by Bernheim, or do really proceed from some magnetic influence, is a question which can only be decided by very careful experiments. In my own experience I have seen nothing to warrant the supposition that there is any special quality in the magnet. Krafft-Ebing found that Ilma Szandor was affected by the approach of any metal which she believed to be a magnet, exactly as she had been by the real magnet. However, Charcot gets transference of paralysis and other functional troubles in hysterical subjects from one side to the other, by passing the magnet over the parts—a proceeding which causes Sir W. Gowers to write: 'The phenomena of transfer (of the genuineness of which, in spite of its rarity out of France, there can be no doubt) show that there must exist an intimate connection between the sensory centres of the two hemispheres, so that the restoration of functional

action in a part of the inhibited centre is accompanied by an arrest of action in the corresponding part of the centre on the opposite side. The validity of this inference is independent of the mode by which the phenomena are effected, or of the exact functional change in which they consist' (*op. cit.*, p. 934).

I don't know whether Dr. Luys has yet applied his treatment to the correction of moral ills. Historians tell us how in the Middle Ages young princes were provided with 'whipping-boys,' whose office it was to bear the penalty incurred by the prince's fault, but from which his august rank was held to shield him. We are told that Edward VI. was of so sensitive a nature that in his case this punishment by deputy was most efficacious.

NOTE 14.—CHRISTIAN SCIENCE HEALING.

As far as I understand the method of healing called *Christian Science*, and similar modes of treatment which, as Sir J. Crichton-Browne told us at Leeds, fall legitimately within the scope of medical inquiry, I believe that the cures they have effected in certain neuropathic conditions depend upon the same factors as we have been considering.

Auto-suggestion is a proved exciter of disease and ill-health, and it is easily conceivable that when directed into healthful instead of morbific channels, it may prove a valuable moral and curative agent.

It is certain that most of those who derive benefit from healthily directed self-consciousness are capable of doing themselves an infinity of harm by morbid introspection if left to themselves.

If a hypochondriacal or nervous invalid can by any means, its name matters not, be induced to look upon himself as healthy and strong, instead of as diseased and weak, a great point is gained, and as he has grown into the miserable creature he imagined himself to be, so it is possible that under different conditions of thought he may realize in his own person some of the perfection upon which he fixes his aspirations. But we must remember that reverie is apt to pass into brooding, and introspection into hysteria, unless very carefully watched. We know

also that ecstatics of all times and creeds have succeeded in becoming careless and unconscious of bodily pain and discomfort, but that this deadening of sensation has not saved them from wasting with disease, and dying from exposure and neglect.

Practically, the contention of the 'Christian Scientist' is that he can bring about spontaneously what the physician certainly succeeds in effecting by the aid of hypnotism, viz., the inhibition of some centres, and the dynamo-genesis of others. Thus, he will tell you that he can become unconscious of the pain of toothache by determinedly denying its existence and fixing his attention on other things.

He says 'mind is all,' and that the body takes its shape from it as the overcoat does from the body. A flippant American critic has observed, apropos of this simile, that a man cannot raise himself off the ground by pulling on his own boot-straps.

The system has been brought lately before the public owing to the deaths of two prominent men who were treated by 'Christian Science' healers. The death of Mr. Harold Frederick, the novelist, whilst under the care of a lady practitioner, was followed by a coroner's inquest, and the healer was committed for trial on the charge of manslaughter. She was, however, acquitted, and the sect still carries on a very active propaganda.

An interesting exposure of some of the most objectionable features of the movement is supplied by Miss Alice Feilding's book entitled 'Faith Healing and Christian Science,' London, 1899.

The following case, which has been recently reported to me, illustrates one of the dangers of 'Christian Science':

Captain B——, an officer living at Aldershot, went out cycling with a friend who was a firm believer and wanted to convert him. Captain B—— after a mile or two complained of pain in the abdomen and wished to return, but his friend assured him that it was only 'mortal mind,' and that he must deny the pain and it would disappear. So

the ride continued, and at the end Captain B—— was in a very prostrate and painful condition. A doctor was called in, who diagnosed peritonitis, and the patient had a severe illness.

Failure to understand the gravity of the pathological condition in this case nearly cost the patient his life; but according to Mrs. Eddy, the arch-priest of the cult, all diseases are the result of error of thought, and are to be treated on the same principle; medical diagnosis is but a pandering to error and 'mortal mind,' and therefore to be severely discouraged. There is a great deal of half-truth mixed up in the absurdities of this creed, and we all know that this mixture makes falsehood the more dangerous.

Unlike the 'peculiar people,' who often figure in the courts as having contributed to their children's deaths by refusing to call in medical assistance in illness, the 'Christian Scientists' appeal to the wealthy and cultured classes both in America, the country of its birth, and in England, and it is quite extraordinary the vogue it has acquired among the upper classes. Some people like to be told that they are gods and possess all potentiality within themselves; but the movement is ephemeral, and only touched upon here from its psychical interest.

I have frequently succeeded, following Dr. de Lagrave's hints, in awakening at a predetermined moment, and no doubt anyone with a little practice will be able to do the same thing; but I imagine that the other effects of auto-suggestion which he relates are only to be attained by hysterical or neuropathic subjects.

Such experiments afford additional proof of the correctness of Bernheim's theory, that in hypnotism it is the patient who hypnotizes himself, and that it is the evocation of his own forces (under the stimulus of suggestion) which constitutes the curative agency in the treatment. Surely this is a better and nobler conception of the power in every way than that current before Braid's time, and still held by unscientific 'magnetizers,' which would have us believe in a subtle fluid passing from operator to subject.

Dr. Byrom Bramwell, speaking of the important part voluntary effort plays in cases of paralysis, instances that of the late Mr. Horatio Ross, a celebrated sportsman.* 'When some eighty-two years of age, Mr. Ross was attacked with hemiplegia which was, perhaps, embolic. He was seen by a distinguished neurologist in London, who, considering the advanced age of the patient and the very serious nature of the attack, gave a very unfavourable opinion, saying that he would never use his arm again. Shortly afterwards he came to Edinburgh and placed himself under the care of Dr. Foulis, who had previously attended him. When he consulted Dr. Foulis, the paralysis of the arm, though not absolute, was very great; the leg, as is usually the case, had to a much greater extent recovered.

'Dr. Foulis, who is a firm believer in the beneficial effects which frequently repeated voluntary efforts produce in cases of paralysis, explained to Mr. Ross the importance of making frequent and systematic efforts to throw the paralyzed muscles into voluntary contraction. Mr. Ross, who was a man of iron will as well as (in his younger days) of iron muscles, fully appreciated the rationale of this method of treatment, and set himself diligently and with firm determination to carry it into effect. Many times every day he endeavoured to perform each of the individual movements which the hand, forearm, and arm are capable of making. The paralyzed muscles soon began to regain some power, and each day, and almost all day, he diligently practised some form of muscular movement. I was asked to see him some two months after he had commenced this treatment, with the object of advising whether electricity would be beneficial. He had then regained considerable movement in the paralyzed arm and much more in the leg. He continued to practise his muscular gymnastics, and in the course of three or four months he had practically recovered; he could, in fact, make such good use of his paralyzed arm

* 'Studies in Clinical Medicine,' vol. i., No. 6.

that, on the following 12th of August, he was able to get on to the moor and actually to shoot several brace of grouse.'

Dr. Bramwell attributes Mr. Ross's rapid recovery to the exercise of the will-power, as each voluntary effort tends to act as a stimulus which travels along the damaged nerve tract and forms a path for motor impulses.

In support of this theory he reminds us that after facial paralysis the orbicularis palpebrarum is the first muscle to recover its tone, on account, he thinks, of its great functional activity. In consequence of the immense number of times each day the reflex stimulus from the conjunctiva —inclination to wink—is applied, the nerve tract is continually being stimulated by impulses which endeavour to force their way through the lesion, and this repeated stimulation leads to rapid repair of the damaged nerve fibres.

The important part will-effort and concentration of purpose play in muscular development and renovation of tissue is seen in Swedish gymnastics, and in the method practised in America under the name of psycho-physical culture. We have much to learn of hypnotism as a stimulator of effort and arouser of the will; it is in this direction the power should be used, and not as a supplanter or enfeebler of individuality.

Note 15.—Hypnotism and Crime.

Recent events, and especially the Gouffé trial in Paris, have brought the question of the employment of hypnotism for criminal purposes prominently before the legal and medical professions, and a word on the subject will not be out of place here. It is very fully discussed by Dr. Liégeois in his book, already referred to, and Mr. Taylor-Innes, of Edinburgh, has treated it at some length in an article in the *Contemporary Review* for October, 1890. Mr. Brodie-Innes states the case in the *Juridical Review* for January, 1891. Dr. Kingsbury has written an able

criticism on the former article in the *Nineteenth Century* for January, 1891, in which he throws great doubt on the possibility of criminal acts being suggested and carried out in the hypnotic or post-hypnotic state; and his arguments, so far as they go, are conclusive. Charcot, also, and his school discredit the idea that hypnotism can be made the vehicle for criminal suggestion, and contend that the subject was perfectly aware of the harmless nature of the act he was committing when, in obedience to Dr. Liégeois, he seized a paper-knife on waking, stole to his wife's side, and stabbed her to the heart. He knew it was acting, and did his part well, that is all—so explains Charcot. The same thing applies to other test criminal actions, as, for instance, the theft of jewellery, or the discharge of a revolver loaded with blank cartridge, either at the patient's own breast or at a stranger's. The subject knew about the trick, and the experiment was simply a laboratory one, which would fail if put to a real test. We here see a curious circumstance, and one which, to my mind, is strong testimony to the thorough-going honesty of the Nancy school. They are engaged in strenuously maintaining that in hypnotism the evil-disposed have a weapon which will give them absolute power over their agents, and insure the accomplishment of crimes without any risk to themselves. What contention could possibly be more fatal to the extended employment of hypnotism which they advocate, or more certain to arouse popular feeling against the treatment? I consider that the question should be met with perfect frankness, and agree with Mr. Brodie-Innes that lawyers should seriously study the possibilities of hypnotism. In approaching the matter, it is necessary to bear in mind a few points in order to be able to arrive at a proper conclusion. In the first place, only a small proportion of the population are sufficiently affected by hypnotism to be reduced to automatism or powerlessness. In a large number even of these the loss of will and self-control is not sufficient to render the subject

absolutely helpless, and in many cases where there is apparent helplessness personal violence or criminal suggestions would restore complete consciousness and the power of resistance. It is difficult, and often impossible, for even a skilful medical man to judge of the precise depth of sleep, and so pronounced a somnambulist as Mrs. H—— often retains a degree of latent consciousness, and remembers subsequently things I have said to her in the hypnotic state ; but no doubt criminal assaults might be committed on women while in the deepest sleep, and in some cases there would be no subsequent recollection of the circumstance. Here we have exactly analogous abuses of chloroform and other drugs, and the criminality should in each case be considered the same. The chief point of interest is not whether hypnotism may be used as an anæsthetic for the performance of brutal outrage, but whether it may be used with any prospect of success as the vehicle for criminal suggestion. I believe that, under certain circumstances, it might be so used, and I here give my reasons for the belief. Hypnotism acts chiefly, as we have seen, by immensely increasing the capacity for receiving, and the desire to act upon, suggestion. It is this property which we make use of in dealing with drunkards and morphinomaniacs, and our suggestions of abstinence and self-control are received and acted upon in proportion to the depth of sleep attained and the natural receptivity of the patient. I have, however, seen suggestion curative in a case of chronic drunkenness where the influence of hypnotism was barely discoverable, and I have seen it fail where somnambulism was induced. In the first case the patient's desire was for cure, and the natural force of moral suggestions had to be but slightly increased in order to obtain success ; whereas in the latter instance the patient had no real desire to give up his bad habit, and the suggestions found no soil in which to take root. I see no reason for supposing that a somewhat similar result would not follow criminal suggestions. It would

be vain to make criminal suggestions to the disciplined and moral man, for he would either wake up at once or would ignore them; but it would be an easy task to corrupt the naturally weak and ill-disposed. If, as has already been said, one told a sincere teetotaler that on waking he was to drink a glass of brandy, it is certain that the suggestion would fail, no matter what was the degree of sleep induced; but the half-hearted abstainer might perhaps succumb, just as he would yield to the pertinacious solicitation of his ordinary companions, because the wish to abstain was not strongly grounded or an essential part of his individuality.* Dr. Norman

* This theory is borne out by some experiments made by Professor Lombroso, of Turin ('Studi su l'Hypnotismo,' Turin, 1886). He hypnotized two medical students of good character, and suggested to them that they were to steal some articles of value. One of them woke up crying, 'No, I will not be a thief;' and the other, after much opposition, did seize the things, but almost immediately threw them from him. On the other hand, the same physician found that a hysterical young woman of doubtful character received with evident satisfaction the suggestion that she was a thief or a brigand, but resisted the assertion that she was a savant or moralist, and declined to give a disquisition on the beauty of virtue. I have never gone so far as to suggest criminal acts to my subjects, and I should regard such a course as very objectionable; but I have suggested lines of conduct opposed to the disposition of the patient, and I have generally seen the order ignored or very partially obeyed. For instance, I suggested to a brother Mason whom I had hypnotized some scores of times, and who is one of the best subjects I have ever seen, that he should tell the secrets of the craft. He became extremely disturbed, and vigorously protested that nothing would induce him to break his oath in such a manner. This patient was so susceptible to my suggestions that if I told him during the hypnotic state that his tie—a red one—was green, he would accept the suggestion and stoutly maintain on waking that it was green. Another patient, who is also a profound somnambulist, though a man of great muscular strength and keen intellect, carries out ordinary post-hypnotic suggestions with accuracy, but when the suggested act is contrary to his volition, he argues the point and does not execute it. For example, I tell him that five minutes after waking he is to take a pin from a pincushion and stick it into the curtain. He does so in a somewhat shamefaced manner, and perhaps says afterwards that he does not know why he did it, but that he felt he must. But when I tell him to pay me a visit at two o'clock on Saturday—the time when he pays his men—he tells me that the thing is impossible, and I am unable to persuade him to consent (see also Dr. Forel's case, p. 172).

Dr. Kingsbury was able to demonstrate this point before the meeting of the British Medical Association in 1890, for his subject, a Manchester merchant, refused to execute any order opposed to his natural temperament.

Kerr's objection to hypnotism, that, if it enables the physician to cure a drunkard, it will enable a scoundrel to debauch a sober man, is, I hold, extremely fallacious.

It is my opinion, and also my experience, that the power in us for good is more potent than that for evil, and that it would be very much harder to make the good man do wrong than to influence the bad man for good. But hypnotism acts by increasing the normal impressionability to suggestion; and as a moral person of unstable character may be corrupted in time by vicious surroundings and evil influences, so, I believe, the same person could be more quickly and surely corrupted by evil suggestions made to him while in the hypnotic state. I have no doubt that many of the subjects taken about with them by travelling showmen have entirely lost all individuality, and have become passive instruments in the hands of their employers. To reduce a fellow-creature to such a condition is, I hold, one of the greatest offences which can be committed against the dignity of humanity; for the position of the unfortunate victim is worse a hundredfold than that of the captive who

---

In the *Dublin Journal of Medical Science*, May, 1891, Sir F. Cruise relates how he saw Dr. Bernheim endeavour to extract a man's political opinions while in a state of profound hypnosis. The patient declined to tell them, and, folding his arms, said, 'C'est mon affaire.' 'What a remarkable contrast to the awkward confessions occasionally volunteered under the influence of chloroform or ether!' is Dr. Cruise's comment on this incident. On the other hand, Liébeault records how, by telling a young girl that he was her father confessor, he succeeded in obtaining her confession. The result must depend upon the patient's disposition and character. For instance, I told one hypnotic patient that she was to resist my suggestions, and yet she was unable to do so, whereas another patient not only resisted my suggestions, but awoke when I insisted upon them. In the debate on hypnotism at the Edinburgh meeting of the British Medical Association, 1898, Dr. Mercier asked if a hypnotized butcher might not be made to murder a man by being told that the victim was a sheep, and that he had to cut its throat in the ordinary exercise of his trade. I think the answer is in the affirmative. Bernheim made an experiment of this nature when he made an honest woman steal another patient's watch. At first she indignantly refused, saying she was not a thief; but when Bernheim assured her it was her own watch which the other woman had purloined, and that she was therefore only regaining her own property, she took it without further scruple. It seems to me better to face a danger and take steps to combat it than to deny or ignore it.

has only to submit to material slavery. It is witnessing degrading performances, and confusing the travesty with rational hypnotic treatment, which makes many well-meaning people look with horror on the present spread of the knowledge of hypnotism. There is a simple means of doing away with much of the danger which may attend its popularization. Let it be regarded as a medical procedure, to be had recourse to only for definite therapeutic purposes by qualified medical men, or as a method of real scientific research in the hands of savants. Let the public be made acquainted with the dangers which attend its use by improper persons, and let its employment in public for purposes of gain or mere amusement be sternly forbidden in England, as it is in other countries.

I do not think the ordinary criminal will ever make use of hypnotism; it is too tedious and uncertain a process. There have been accounts in the papers of various crimes alleged to have been committed by its means. Some boys in Pesth were a little time ago stated to have robbed their masters' tills in obedience to hypnotic suggestion, and an ingenious newspaper correspondent was quite sure that the Whitechapel murders were the work of someone acting under hypnotic influence! My opinion is that the malefactor, unfortunately, finds plenty of material ready to his hand without hypnotism, and that the weak and criminal actions of bad men and women are capable of a much simpler explanation.

Supposing that a hypnotizer got absolute control over a subject, and rendered him so sensitive to his suggestions that he could induce him to commit thefts and other crimes, and at the same time be unconscious of the prompting which had impelled him, could the subject be hypnotized by another person, and made to give up the secret? I believe he could after a longer or shorter period, and that the real criminal would then be discovered. Moreover, the person acting under controlling suggestion would almost certainly perform the action in a manner different to his ordinary behaviour. He would

appear more or less dazed, and would probably make either no effort or only a very inadequate one to escape capture.

In the event of a criminal action being committed through hypnotic suggestion, expert evidence will be forthcoming to completely establish the case.

I think, however, a false plea of having acted under hypnotic compulsion is a much more probable event than the perpetration of crime through such agency. It is not unlikely that we shall have persons demanding blackmail for alleged felonious hypnotization, as we have had from time to time similar accusations of administering chloroform.*

The alleged dangers of hypnotism may be ranged, then, under three heads: As they affect the morals, pocket, and health of the subject.

First, those to which the patient is liable while actually in the hypnotic trance. These embrace crimes of violence, and especially indecent assault or violation. The use of chloroform is attended with the same risk, and criminal reports show that there is real danger of this abuse. I venture to think that there is less danger on this score from hypnotism than from drugs, on account of the comparatively small number of persons who are susceptible to such a degree as to become anæsthetic and amnesic.

The second danger is a much more serious one, and if the allegations made against the abuse of mesmerism were true, they went far to justify the attitude the profession adopted towards it fifty years ago. It was alleged that persons became absolutely under the control of the mesmerist, and that such control could be, and on many

* It looks as if the plea of having acted under hypnotic suggestion is to become a matter of course in French *causes célèbres*. The papers have been filled with the reports of a sensational trial in Algeria. A Madame Weiss was found guilty of attempting to poison her husband, and she pleaded that she had acted under the control of her lover, who had hypnotized her, and whose suggestions she was unable to resist. The woman was thoroughly degraded, and her accomplice was an unscrupulous villain; but the whole affair was a commonplace crime enough, and easily explicable without calling in the aid of hypnotism.

occasions was, exercised, not only during the mesmeric sleep, but subsequently, for purposes of immorality and to extort money. It was even believed that this power could be exercised at a distance, and against the will of the subject.

More evidence of the possibility of the operator being able to influence the subject at a distance is still wanted, but the experiments of Professor Pierre Janet, of Havre, and Professor Liégeois, of Nancy, seem to show that under special circumstances and in rare instances a subject who has been hypnotized a great number of times by the same operator may be sent to sleep by the hypnotizer exerting his will from a distance. I have come to this conclusion with extreme unwillingness, for it seems to open up the possibility of a man or woman being reduced to a state of complete mental and moral slavery.*

* Examples of this are given in the works of Liégeois, Liébeault, and Bourru and Burot. Liébeault describes a series of experiments with Camille, a very hysterical subject well known to those who have visited Nancy. Camille, unconscious of the experiment, was in Dr. Liébeault's garden, and Dr. Liégeois in the dispensary. The distance between them was 29 mètres, and subject and operator were concealed from one another by a thick hedge. Dr. Liégeois simply fixed his mind on the idea of making Camille sleep. In eight minutes she was actually asleep, and it was found that she was *en rapport* with the Professor and with no one else. He had hypnotized this subject a great number of times, and the experiment failed when Dr. Neilson endeavoured to repeat it under the same conditions. Dr. Beaunis, however, who had also frequently hypnotized her, was also able to send her to sleep from a distance (Liébeault, *op. cit.*, p. 275).

Drs. Gibert and Janet experimented on Mde. B——, at Havre, in the presence of several competent witnesses. They succeeded in sending her to sleep by mental suggestion when she was some kilomètres from them, and ignorant of what was going on. But they failed to influence her to commit definite acts. They could also awaken her by mental suggestion from a distance (Bourru et Burot, 'La Suggestion Mentale,' p. 160).

I have several times made a similar experiment on two or three of my most susceptible subjects, and have tried to hypnotize them by directing my thoughts on the purpose in view at various distances, but I have never noticed any effect. While, therefore, admitting its possibility, I feel convinced that the phenomenon is very rare. Hypnotism here, as in other directions, merely intensifies existing states. The researches of the Society for Psychical Research have completely proved the reality of telepathic influence, and hypnotism, by withdrawing the mind from the life of relation, intensifies the sensitiveness of those few persons who are susceptible to telepathic impressions.

I believe such dependence can only be possible in cases where the hypnotist has dominated the same subject a very great number of times, and then only in very exceptional cases. We have the consolatory legal maxim *de minimis non curat lex*, but I think attention should be drawn to the possibility of such a thing with a view to averting its occurrence.

The Nancy theory of the all-powerfulness of post-hypnotic suggestion introduces an additional element of danger into the practice of hypnotism, and if Professor Liégeois's ideas were justified, they would, I think, afford a very grave argument against the popularization of the treatment. But most observers regard these ideas as exaggerated and somewhat fanciful, and the dangers opened up by them as chimerical. Still, the fact remains that there are a few persons in every thousand who are so influenced by suggestion as to be incapable of resisting the orders of the hypnotist even after long intervals of time, and who can be made to execute these orders as of their own initiative, and without being conscious of their source.

Occupying a somewhat middle ground between these two dangers is the risk of a person being made to sign cheques, forge documents, make promises, etc., while in a state of lucid somnambulism. Thus, Dr. De Watteville easily persuaded the 'Soho sleeper' to sign an I.O.U. But this danger does not appear to me at all so serious as that arising from post-hypnotic suggestion, for the subject would be able on waking to recognise the fact that he had been fradulently dealt with, and to offer opposition subsequently. Moreover, the danger of such fradulent proceedings is not confined to hypnotism, for signatures and promises have been extracted from persons through the instrumentality of intoxicating and stupefying drugs, and the law knows how to deal with such abuses.

The third alleged danger is happily non-existent. When hypnotism is carefully employed for therapeutic purposes, injury to the subject's physical, moral, or mental health is

never caused. That careless and ignorant tampering with hypnotism is dangerous has been sufficiently shown by the cases I have cited, in which grave nervous disturbances have been proved to follow its illegitimate employment (*vide* p. 115). There is still another danger attending its popularization which medical men will do well to be on their guard against, viz., blackmailing and false accusations, for they may be accused of improper conduct in respect to hypnotism, just as they are with regard to chloroform.

It is to be hoped that this possibility, while making them very careful, will not prevent them recommending the use of hypnotism when the patient's condition is such as to benefit from it.

Note 16.—The Hypnotic Will Case.

In July, 1898, there was a sensational law case in which I was subpœnaed to give evidence. Dr. Kingsbury, of Blackpool, was appointed executor and residuary legatee under the will of an old lady patient. The son as heir-at-law disputed the will on the ground of undue influence, and it was alleged that the doctor had hypnotized the patient, and by hypnotic suggestion had got her to make the will in his favour. The charge entirely broke down, and Dr. Kingsbury won the verdict.

It came out in the evidence that Mrs. Howard was on bad terms with most of her family, including the plaintiff, that she was greatly attached to Dr. Kingsbury, and that he had been very devoted in his attendance on her for more than ten years, and was her confidential adviser in all her difficulties. They used to talk a good deal about hypnotism, in which she knew he was much interested, and in 1894 she asked him to try to hypnotize her, as she suffered from sleeplessness.

Dr. Kingsbury consented to try, though he told her he did not think hers a suitable case. He was seeing her daily, and every day for three weeks, in the presence of her maid, he endeavoured to influence her hypnotically. But

the attempt failed and he fell back upon ordinary treatment.

Mr. Carson, Q.C., laid great stress upon the number of times Dr. Kingsbury hypnotized his patient, and the jury was asked to imagine the old lady lying helpless under his suggestions. Sir Edward Clarke, however, was able to put a different complexion on the matter, and the jury decided for Dr. Kingsbury.

In this case it was evident that hypnotism was introduced to prejudice the jury, and it is quite possible that had Dr. Kingsbury's position been less established at Blackpool he might have lost the suit. An interesting feature of the case was the evidence of Sir William Broadbent, who was called by Dr. Kingsbury. He was a member of the Hypnotic Committee of the British Medical Association, whose report is given on p. 372, and he expressed in court his continued adherence to the opinions therein set forth. Under French law the legacy would have been invalid, for in France medical men are not permitted to benefit from wills of persons under their care.

I have met with two cases which show the caution necessary in dealing with hypnotism. Strangely enough, I was consulted in both instances on the same day. The first case was that of a young lady of good education and position. She thought herself the victim of a plot hatched by two young men of her acquaintance to influence her telepathically ; and she was under the impression that they could at any time direct her thoughts and actions from a distance. Though she had never been hypnotized, she supposed that hypnotism had something to do with it.

I found her, like all persons who suffer from a fixed idea, very difficult to hypnotize, but after six attempts I succeeded in inducing a state of mental receptivity, with inability to open the eyes. I suggested that she would become insusceptible to telepathic influences, and would recover her self-confidence and spirits. She almost immediately began to feel stronger in mind and less hysterical, and in three weeks she went home thoroughly convinced that in future she was proof against such influences. Suggestion alone did not suffice to remove the false ideas, for several medical men and others had tried argument in vain. The idea was too deep-seated to be stirred by ordinary methods, and from the way things were tending, I have little doubt but that the patient would very soon have drifted into melancholia or dementia. Her suspicion that hypnotism had something to do with her symptoms is interesting. There is no doubt but that as the subject comes more into vogue we shall find a great number of persons will imagine themselves victims of this, to them, mysterious

agency. The electric telegraph and telephone have been credited by scores of insane persons with being the source of their troubles, and hypnotism is a very likely thing for the mental patient on the look-out for a delusion to take up.

The other case is more serious because, unfortunately, it has not, so far, been found possible to correct the evil. A lady who has for years carried on reformatory work in a Midland town was greatly impressed by the evidence she had heard of the success of hypnotism in curing the craving for drink, and instead of procuring the services of a medical man, she experimented on some of her girls herself. Girls of this class are notoriously susceptible to hypnotism, and she found no difficulty in sending five out of the seven she operated on into somnambulism. The result surpassed her expectation, and three of the five girls seem to have been absolutely cured, and to have remained perfectly sober ever since. Two of the others, influenced by bad companions, have turned upon the unfortunate lady, accuse h r of having hypnotized them for immoral purposes, and have made the situation altogether so uncomfortable that she will probably have to give up her work and quit the town. I have hypnotized many women of the same class in institutions, and have never noticed anything peculiar; but this lady tells me that on each occasion she hypnotized those girls they awoke in a somewhat dazed state, and were under the impression that they were with their former companions and in their old haunts.

* * * * * *

As the question of the State regulation of the use of hypnotism may at any moment become a burning one, I here append the draft of an Act which was approved by the Royal Belgian Academy of Medicine, and discussed by the Belgian Parliament in 1891. It is now, I believe, the law of the land.

LÉOPOLD II.,

ROI DES BELGES.

À tous présents et à venir, Salut.

Sur la proposition de Notre Ministre de la Justice,

NOUS AVONS ARRÊTÉ ET ARRÊTONS:

Notre Ministre de la Justice est chargé de présenter, en Notre nom, aux Chambres législatives, le projet de loi dont la teneur suit :

ARTICLE 1.

Quiconque aura donné en spectacle au public une personne hypnotisée par lui-même ou par autrui, sera puni d'un emprisonnement de quinze jours à six mois et d'une amende de vingt-six francs à mille francs.

ARTICLE 2.

Quiconque, n'étant pas qualifié pour exercer l'art de guérir, aura hypnotisé une personne qui n'avait pas atteint l'âge de dix-huit ans accomplis ou n'était pas saine d'esprit, sera puni d'un emprisonnement de quinze jours à un an et d'une amende de vingt-six francs à mille francs, alors même que la personne hypnotisée n'aurait pas été donnée en spectacle au public.

En cas de concours avec les infractions punies par les dispositions légales concernant l'art de guérir, la peine prononcée par le présent article sera seule appliquée.

ARTICLE 3.

Sera puni de la réclusion quiconque aura, avec une intention frauduleuse ou à dessein de nuire, fait écrire ou signer par une personne hypnotisée un acte ou une pièce énonçant une convention, des dispositions, un engagement, une décharge ou une déclaration. La même peine sera appliquée à celui que aura fait usage de l'acte ou de la pièce.

Donné à Laeken, le 14me avril, 1890.*

LÉOPOLD.

PAR LE ROI :
Le Ministre de la Justice,
JULES LE JEUNE.

* *Juridical Review*, January, 1891.

REPORT OF THE COMMITTEE APPOINTED TO INVESTIGATE THE NATURE OF THE PHENOMENA OF HYPNOTISM; ITS VALUE AS A THERAPEUTIC AGENT; AND THE PROPRIETY OF USING IT.

The Committee, having completed such investigation of hypnotism as time has permitted, has to report that they have satisfied themselves of the genuineness of the hypnotic state. No phenomena which have come under their observation, however, lend support to the theory of 'animal magnetism.'

The experiments which have been carried out by members of the Committee have shown that this condition is attended by mental and physical phenomena, and that these differ widely in different cases.

Among the mental phenomena are: altered consciousness, temporary limitation of will-power, increased receptivity of suggestion from without, sometimes to the extent of producing passing delusions, illusions, and hallucinations, an exalted condition of the attention, and post-hypnotic suggestions.

Among the physical phenomena are vascular changes (such as flushing of the face and altered pulse-rate), deepening of the respirations, increased frequency of deglutition, slight muscular tremors, inability to control suggested movements, altered muscular sense, anæsthesia, modified power of muscular contraction, catalepsy, and rigidity, often intense. It must, however, be understood that all these mental and physical phenomena are rarely present in any one case. The Committee take this opportunity of pointing out that the term 'hypnotism' is somewhat misleading, inasmuch as sleep, as ordinarily understood, is not necessarily present.

The Committee are of opinion that as a therapeutic agent hypnotism is frequently effective in relieving pain, procuring sleep, and alleviating many functional ailments. As to its permanent efficacy in the treatment of drunkenness, the evidence before the Committee is encouraging, but not conclusive. Dangers in the use of hypnotism may arise from want of knowledge, carelessness, or intentional abuse, or from the too continuous repetition of suggestions in unsuitable cases.

The Committee are of opinion that when used for therapeutic purposes its employment should be confined to qualified medical men, and that under no circumstances should female patients be hypnotized except in the presence of a relative or a person of their own sex.

In conclusion, the Committee desire to express their strong disapprobation of public exhibitions of hypnotic phenomena, and hope that some legal restriction will be placed upon them.*

(*Signed*) F. NEEDHAM, *Chairman.*
T. OUTTERSON WOOD, *Hon. Sec.*
